The model performance for evaluating these scenarios will also depend on the model representation of geological layers and hydraulic properties, particularly permeability. The spatial distribution and parameterisation of the multiple layers of aquifer and aquitards within the model have been based on available evidence, including many drilling investigations and hydraulic tests, and more recently, core testing and the 6-month aquifer pumping test. There is also an extensive record of data on aquifer and stream flow responses to mining and groundwater pumping, which has been used for model history-matching, demonstrating sound performance.

There are several lines of evidence that the aquitards that separate shallow and deeper groundwater near the mine site are relatively thick and are low permeability. The types of different tests and evidence of aquitards limiting vertical flow pathways presented by EHS (2022) is similar to approaches near other mine sites to test the integrity of aquitards and probability of vertical connectivity (e.g. McMillan et al 2022).

The possibility of minor groundwater flow through small scale geological features (e.g. sand lenses), that are smaller than might be mapped or modelled, cannot be discounted. However, if these features were to exist, the influence on water balance and/or drawdown in the swamps, would be minor by definition, and could be evaluated with modelling scenarios. There are also potential risks further away from the mine pit void, where the EUV aquitards are thinner and the UEV lower sands (and LEV) are closer (vertically) to the swamp. If there is a high risk that such potential flow pathways could influence water quality (e.g. acidity), surveys and monitoring may be warranted.

4.6.4 Mine Pit Water Quality

It is understood that potentially acid forming overburden has been selectively placed and encapsulated within the Anglesea mine pit. It is noted that groundwater from the borefield that is proposed to be discharged into the Anglesea mine pit has a pH of 5.5 before it is added to the current mine pit water body, which has a pH of 3.5. These processes are not represented in the groundwater model.

4.6.5 Subsidence

The risk of new land subsidence is generally a process related to:

- a new maximum drawdown of groundwater (ie. new groundwater pumping rate greater than previously) of compressible saturated strata at depth

and/or

- desaturation of peaty sediment near the land surface

and/or

- shallow geological strata that subsides due to extraction of underlying strata (ie. tunnelling or underground mining subsidence (Hebblewhite, 2022) as distinct from open pit mining at Anglesea).

There has been no detailed evaluation of the possibility that subsidence may have occurred in these areas since the late 1960s. However, the assessment of the risks of borefield use on land subsidence is a regulatory objective for Barwon Water and the TRP have considered the risk of subsidence in reviewing the groundwater modelling approach. The TRP note that the risk of

subsidence will be low if groundwater drawdown in the future is at low to moderate pumping rates compared to previous rates of pumping. The TRP therefore concur that the groundwater model objectives do not include subsidence assessment and subsidence is not examined in the groundwater model.

4.7 Recommended ongoing monitoring and investigations

As best practice guidance recommends strong linkages between monitoring, modelling and investigations to provide support for adaptive management, additional data should be collected.

Gaps in the groundwater monitoring network should be filled with additional multi-level piezometers (e.g. in the ASA lower catchment areas where there is no monitoring, to augment WTOB1 and WTOB2), and other monitoring bores with poor integrity should be replaced to ensure continuity of reliable data.

Crucial monitoring data includes groundwater levels and surface water flows/levels, along with water quality (acidity especially in the swamps/ASA, rivers/creeks and estuary, plus a range of parameters i.e., salinity, pH and EC, DO, Fe^{2+}), augmented by investigation of ecological responses to changes in acidity from upstream to the estuary will help to understand the drivers of environmental impacts.

5. Conclusions and Recommendations

The model objectives are clearly defined; to develop a single Anglesea groundwater model that can meet the ongoing water management and planning obligations of both Barwon Water and Alcoa, to support:

- the Alcoa mine closure and rehabilitation planning and management works, including the licence application to SRW for long-term groundwater abstraction to fill the pit water body;
- the Barwon Water Anglesea borefield planning, management and approvals works under the Bulk Entitlement (BE) process, including re-assessment of the sustainability of groundwater extractions for urban water security purposes.

The groundwater model is suitably designed and built for the intended objectives and predictive scenario forecasting purposes, and adequately represents the hydrogeological conceptual model. The reasonable calibration/history-match performance provides confidence that the Anglesea model is a suitable predictive tool under a range of climate and other stresses for surface water and groundwater interactions, interactions with the pit, interaction between the main aquifers, groundwater trends, water balances, pit water levels, flux exchanges and parameter realisations. The overall methodology and execution are consistent with best practice guidelines, including for uncertainty assessment (Barnett al 2012; Peeters and Middlemis 2023) and climate change (DELWP 2020), subject to review of the scenario design in progress.

The groundwater model is not designed to directly investigate acid mobilisation events, but it can provide objective insights given its capability to simulate groundwater levels, groundwater flows, and surface water flows under a range of climatic and pumping conditions. Recommendations for ongoing modelling include the following.

- The upcoming scenario forecasting and differencing task should be designed to provide groundwater model outputs for use in detailed analysis of acid mobilisation and thus to confirm whether or not the combined groundwater modelling and geochemical analysis methodology has suitable capability for the assessment acid-related effects.
- Scenario forecasts should include no pumping and low or moderate pumping rates compared to the much higher rates of groundwater extraction during mining (i.e. the model has been tested within this range), and with extraction from either or both Alcoa and Barwon Water borefields able to be included. The model is also suitable for use in a data worth analysis to identify optimum sites for filling gaps in the monitoring network (eg. in the ASA, such as in the lower catchments to augment the existing bores WTOB1 and WTOB2).

The modelling methodology is founded on the latest uncertainty analysis methods, and the results are designed to aid decision-making through presentation of combinations of:

- the magnitude of effects of groundwater extraction:
    - eg. groundwater levels and drawdowns in the aquifers; river flow-duration and zero flow period changes with time; aquifer flux exchanges with rivers and swamplands; pit lake levels and water balances; etc.
- the probability of occurrence of those effects:

key metrics of 5%, 50% and 95% likelihood ('P5, P50 and P95') of predicted impacts exceeding or not exceeding established triggers at sensitive/key sites such as groundwater dependent ecosystems and at stream flow gauges, and with consideration of climate change effects, consistent with DEECA guidelines.

7. Appendix A – Glossary

7.1 Glossary of key terms used in this report

Table **2** - Glossary of key terms

Term	Description
Adaptive Management	An approach to natural resource management that comprises implementing management action, monitoring and evaluating outcomes and systematically adapting those actions according to what is learned.
ASA	Alluvial Swamp Aquifer (swampland sediments)
ASS	Acid Sulfate Soils
calibration / history match	The modification of model input data in a systematic fashion (eg. aquifer and aquitard parameters, recharge, boundary conditions) and repeatedly running the model over the history-match period until the model output matches measured data within an acceptable level of accuracy.
CHM	Conceptual Hydrogeological Model - a simplified and idealised representation (usually graphical) of the physical hydrogeologic setting and our hydrogeological understanding of the essential flow processes of the system; includes the identification and description of the geologic and hydrologic framework, aquifer media type, hydraulic properties, sources and sinks, and important aquifer flow and surface-groundwater interaction processes.
EVF (EVF, UEVF, LEVF)	Eastern View Formation (EVF, Upper EVF, Lower EVF)
Fit for purpose	Peeters and Middlemis (2022, in press) propose a model as fit for purpose when it is useful, reliable, and feasible for its given context. A groundwater model can be considered fit for purpose in the context of impact assessment for coal mines and coal seam gas developments when it provides: • objective evidence that the uncertainties affecting decision-critical predictions of impacts on aquifer resources and dependent systems are not underestimated, and; • information about uncertainties in the conceptualisations and model simulation outputs in a way that allows decision makers to understand the effects of uncertainty on project objectives (echoing the AS/NZS ISO 31000:2009 risk definition) and the effects of potential bias.
Groundwater Dependent Ecosystem (GDE)	Ecosystems that require access to groundwater on a permanent or intermittent basis to meet all or some of their water requirements so as to maintain their communities of plants and animals, ecological processes and ecosystem services. GDEs include terrestrial vegetation, wetlands (swamps, lakes and rivers) and ecosystems in aquifers and caves.
GMA	Groundwater Management Area
Model – conceptual	See also CHM - Conceptual Hydrogeological Model. A descriptive and/or schematic hydrological, hydrogeological and ecological representation of a site,

	environment or process showing the stores, flows and uses of water, which illustrates the geological formations, water resources and water-dependent ecosystems. It provides a basis for developing water and salt balances and inferring water-related ecological responses to changes in hydrology, hydrogeology, and water quality.
Model – numerical	Computer codes that enable simulation of physical systems and processes such as groundwater and/or surface water flow and can be applied to assess the potential impacts of a project or management plan. Similar to analytical models in that they make simplifying assumptions; however, features of the governing equations and boundary conditions in numerical models (e.g., aquifer geometry, hydrogeological properties, pumping rates or sources of solute) can be specified as varying over space and time. This enables more complex representations of groundwater or surface water systems than could be achieved with an analytical model.
Quantity of Interest (QoI)	A model outcome from a specified model scenario, with a predefined spatial and temporal setting, that is relevant to assessing the likelihood and consequence of a causal pathway element representing a hazard. An alternative term is 'key prediction or scenario forecast'.
sustainable groundwater extraction	The groundwater extraction regime, measured over a specified planning timeframe, which allows acceptable levels of stress and protects the higher value uses that have a dependency on the water.
DELWP	Department of Environment, Land, Water and Planning
DEECA	Department of Energy, Environment, and Climate Action
DJPR / ERR	DJPR-ERR was previously known as Department of Jobs, Precincts and Regions - Earth Resources Regulator, and it has now been incorporated into DEECA
Inter-Agency Group (IAG)	comprises representatives from DELWP, SRW and DJPR/ERR who have shared responsibilities for, and interest in, various aspects of groundwater management in the Jan Juc GMA
SRW	Southern Rural Water One of four rural water corporations in Victoria. Responsibilities include the regulation of surface water, groundwater licensing and dams and managing the bulk entitlements for environmental water, power generation companies and the raw water for some regional and urban water corporations to treat for drinking water.
TRP	Technical Review Panel appointed by DELWP
TAP	Technical Advisory Panel appointed by SRW

Terminology Descriptions

Term	Description
Ash	Produced from the burning of brown coal at the former power station. A combination of bottom and precipitator/fly ash
Berm	Constructed at the toe of the consolidated leached ash area to bund drainage water from sluiced ash. Constructed of clay rich material sourced from the overburden
Clay Rich Cover	Constructed to cover the consolidated leached ash area. Comprises clay rich material sourced from the overburden
Consolidated Leached Ash	Combination of sluiced and dried leached ash consolidated into an approximate area of 4.6 ha in the south-east corner of the former mine pit
Fill Material	Backfilled overburden which surrounds the consolidated leached ash area
Leached Ash	Ash produced from the power station was sluiced into Ash Pond 1. Stored under water for years during which salts and metals were leached from the solids
Overburden	Demons Bluff Formation and Boonah Formation lithologies removed to extract underlying brown coal

1 Introduction

In September 2017, Alcoa of Australia Ltd ("Alcoa") submitted a draft Mine Rehabilitation and Closure Plan (MRCP) to Earth Resources Regulation (ERR) providing a plan that would ensure that the rehabilitation of the Anglesea coal mine (**Figure 1**, attached) would provide a safe, stable, and sustainable landform for the future that compliments the surrounding natural environment.

The draft MRCP recognised that leached ash has historically been placed into the former open cut coal mine (also referred to as the mine pit) in accordance with the Mine Work Plan endorsed by ERR in September 2011 and included an assessment of the risks associated with submerging the material within the proposed water body which concluded that risks to the environment were low.

In 2017, consistent with the draft MRCP, the leached ash material located within the south-eastern corner of the mine pit was consolidated for covering[1]. Approval was provided by ERR in December 2017, in consultation with the Environment Protection Authority Victoria (EPA), which allowed Alcoa to cover the consolidated leached ash (CLA) with at least 1 m of clay rich overburden material. The draft MRCP proposed that the CLA would be:

'…encapsulated with approximately 1 m of clay spoil and overburden material, and from below by the presence of a low permeability basal clay unit within the base of the mine pit.'

Redeposition and grading of the final CLA area was completed early 2018.

As part of this approval, ERR included several future considerations and requirements including the following, that '*… the potential impacts on water chemistry, hydrology, hydrogeology, and stability will be considered in Alcoa's revised rehabilitation and closure plan.'*

Based on re-commenced discussions between Alcoa, ERR, and EPA in 2021, and to respond to the feedback from ERR (and EPA) in 2017, Alcoa engaged EHS Support to undertake the following:

- Further field investigations and sampling in the vicinity of the CLA;
- Numerical modelling related to potential mine pit water body level increase and groundwater seepage; and
- Technical risk assessment related to submerging of the CLA.

In September 2021, samples representative of CLA material, the clay-rich layer,[2] and fill material[3] were collected in the south-eastern corner of the mine pit. Laboratory reporting included physical characterisation in addition to total and leachable fraction analysis. Permeability results indicated CLA permeabilities ranging from $1x10^{-9}$ to $7x10^{-10}$ m/sec and clay-rich layer permeabilities of $2x10^{-9}$ to $2x10^{-10}$ m/sec.

[1] As discussed with ERR/SRW/EPA on 19 December 2023, Alcoa noted that ash was historically placed elsewhere within the mine leased area which was in accordance with the regulatory regime in place at that time. The purpose of the CLA technical risk assessment is to specifically assess the risk of inundation of the CLA located in the south-east corner of the former mine void, which Alcoa can also confirm is the only ash material within the existing mine void that will be subject to inundation by the future water body. As such Alcoa considers that historical ash placement outside of the existing mine void is not relevant to this CLA technical risk assessment.

[2] Clay-rich material sourced from Demons Bluff Group used to cover consolidated leached ash by at least 1 m

[3] Consisting of reworked and back filled Demons Bluff Formation and Boonah Formation sands, silts and clays

On 20 October 2021, following discussions with Alcoa, the EPA advised Alcoa in a letter entitled 'Approval pathway under the Environment Protection Act 2017', that the following information should be provided related to the CLA area:

1 *detailed design of the landfill cap;*
2 *a description of the targeted performance (short- and long-term) and outcomes of the proposed landfill cap;*
3 *information that supports how the proposed cap can achieve the targeted performance and outcomes;*
4 *monitoring results capable of confirming that the cap is performing in line with targeted performance and outcomes (short- and long-term);*
5 *detailed and verifiable confirmation that the proposal constitutes the best available techniques;*
6 *independent technical peer-review of a qualified expert (or experts) that have expertise suitable to undertaking a technical peer-review of the proposal; and*
7 *measures taken to comply with the General Environmental Duty (GED), relevant Environment Reference Standards (ERS) and principles of the Environment Protection Act 2017.*

This document provides information in response to the above requirements, and to respond to the feedback received from ERR (and EPA) in a letter dated 29 November 2017 and entitled 'RE: Alcoa Anglesea – Ash Covering Management Commencement' in response to the sections of the draft MRCP related to CLA. An assessment of the management and characterisation of the CLA material, a review of national and international examples of the sub-aqueous storage and disposal of leached ash, water quality performance targets, numerical groundwater modelling and particle tracking, and an overall risk assessment for the activity of submerging the CLA material is provided.

1.1 Objective

The main objective is to complete a detailed technical and risk assessment for the activity of submerging the CLA material covered by at least 1 m of low permeability clay-rich overburden to understand any associated short and long-term risks to the environment. This also then provides information to support Alcoa's response to address the feedback provided by the EPA in the letter dated 21 October 2021, and the original feedback received from ERR and EPA in November 2017.

The overall intent of this assessment is to determine the risk to human health and the environment by the presence of and the submerging of the CLA material in the former mine void. A hypothesis has been defined to aid the process of assessment:

> *Hypothesis – the submergence of the encapsulated consolidated leached ash will not result in adverse risk of harm to human health or the environment within the catchment.*

This hypothesis will be examined throughout this assessment using historical data and targeted site investigations which have been used to develop a suitable numerical model. This process has been subject to an independent technical peer review by BlueSphere.

1.2 Summary

Alcoa has undertaken a detailed risk assessment of the CLA area in the south-eastern corner of the mine pit which considers the future proposed inundation of the CLA area as the water body fills. This detailed review (inclusive of independent peer review) demonstrates that the risks of harm from the presence of CLA within the former mine pit are low and has been minimised so far as is reasonably practicable. The main risk mitigation measure adopted by Alcoa is the encapsulation of the CLA in a low permeability (sandy clay) fill material, on average less than $1x10^{-9}$m/sec. In addition to this, leachable fraction analysis of the CLA demonstrates that ash pore water is unlikely to have any measurable environmental impacts in either groundwater or the water body, currently or in the future. Groundwater monitoring wells are located in the vicinity of the CLA area (Demon Bluff Group [DBG] MB4, DBG MB5, and DBG MB6) and are screened within the clay -rich fill material. These locations have been part of the groundwater monitoring network surrounding the mine area since 2021 and will continue to be monitored as the CLA area is inundated by the water body.

Numerical groundwater modelling and particle tracking analysis using the permeability characteristics of the CLA and encapsulating clay-rich fill material also supports minimal migration of conservative particles in groundwater. The modelling showed that under all simulated scenarios (natural and fast fill) the water body evolves as a groundwater sink. In the fast fill scenario (where supplementary water is used to fill the mine pit), maximum particle movement is 41 m in 200 years and groundwater flows away from the water body for less than 20 years. These distances are significantly less than the distance to the edge of the mine disturbed area of approximately 400 m.

The above outcomes are supported by a detailed risk assessment that indicates only low or rare risks in both the short and long term associated with the activity of submerging the CLA area and regardless of the water body filling strategy. In accordance with Part 3 Division 6 Section 44 of the Mineral Resources Sustainable Development (Mineral Industries) Regulations (2019), Alcoa has identified potential mining hazards and assessed risks associated with covering and submerging the CLA area located in the south-east corner of the mine. This process involved several steps, consistent with those outlined in 'Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS' **Appendix B** (December 2020 version 1.3) (Victoria, 2020) provided by the Department of Jobs Precincts and Regions.

Finally, an independent peer review (IPR) of this technical assessment was completed by BlueSphere Environmental Pty Ltd (BlueSphere). Refer to **Appendix A** for IPR letter.

This Consolidated Leached Ash Technical Assessment provides the technical information supporting the Alcoa proposal to submerge the CLA material. This was in accordance with the Mine Work Plan endorsed by ERR in September 2011. The CLA area was covered by at least 1 m of low permeability clay rich overburden meeting Alcoa's GED and demonstrating that the low risks associated with this activity to the environment have been reduced as far as reasonably practical in the short and long term.

The following Sections provide further information on the items detailed by the EPA in the letter to Alcoa dated 20 October 2021, and also addresses the feedback received from ERR in their letter to Alcoa dated 29 November 2017 **Appendix B**.

Table 1-1 Report Sections Addressing EPA Queries

EPA Query	Section	Content
1. Detailed design of the landfill cap	**Section 5.2.1**	CLA design methodology.
2. A description of the targeted performance (short- and long-term) and outcomes of the proposed landfill cap	**Section 7**	Performance based on de-ionised and saline water permeameter tests and thickness of clay-rich material surrounding the CLA, long-term performance of a low permeability material is expected in contact with saline groundwater and CLA porewater.
3. Information that supports how the proposed cap can achieve the targeted performance and outcomes	**Section 5**, **Section 7**, **Section 9**	Knowledge and documentation of the CLA placement, the clay-rich cover and surrounding fill material. Spatial distribution of field sampling and permeability results. Numerical groundwater modelling.
4. Monitoring results capable of confirming that the cap is performing in line with targeted performance and outcomes (short- and long-term)	**Section4**, **Section 6**, **Section 7**, **Section 9**	Soil sampling results from 2021 and 2022. Ongoing surface water and groundwater sampling results from the mine pit water body and monitoring bores in the vicinity which are screened within the fill material and DBF and BF surrounding the CLA area. Interim Water Quality Performance Targets.
5. Detailed and verifiable confirmation that the proposal constitutes the best available techniques	**Section 5**, **Section 8**, **Section 9**, **Section 10**	Use of low permeability clay-rich material, placement of material in lifts to minimise voids above the consolidated leached ash and surrounding with low permeability clay-rich material. Literature review of national and international examples of (leached) ash management. Use of numerical groundwater modelling to demonstrate the efficacy of the surrounding low permeability materials.
6. Independent technical peer-review (ITPR) of a qualified expert (or experts) that have expertise suitable to undertaking a technical peer-review of the proposal	**Section 2**	BlueSphere have undertaken a technical review of the assessment, refer to **Appendix A**.
7. What are the measures taken by Alcoa to ensure compliance with the GED, relevant ERS and *Environment Protection Act 2017*.	Entire document but specifically: **Section 3**, **Section 5**, **Section 9**, **Section 10**	Entire document.

2 Independent Peer Review

An independent technical peer review was completed by BlueSphere Environmental Pty Ltd (BlueSphere). BlueSphere were engaged throughout the development of the technical review and involved at each stage of the process. The peer review identified a number of improvement opportunities during the process which have been actioned and included as part of this final technical assessment, which has significantly improved the level of confidence in the conclusions reached within this report.

BlueSphere concluded that:

- The combined assessment and characterisation work on the physical properties of the CLA is considered to have been completed in accordance with appropriate and relevant legislation, guidance, and industry standards to the extent practicable. The outcomes of this work are considered to be a reasonable basis from which to assess the likely future impacts on the surrounding environment from the submergence of the CLA within the pit lake.
- Numerical modelling has been utilised to make predictions regarding the future environmental performance of the CLA cap and other encapsulating materials. The model is considered to be sufficiently rigorous given the setting, margin of safety indicated by the modelling results, and relatively modest modelling objectives.
- The numerical modelling together with other lines of evidence, including the site-specific physical characterisation of the materials, has been used to inform the risk assessment process. The risk assessment concludes that the activity of submerging the CLA beneath the pit lake represents a low risk of adverse environmental outcomes in both the short and long term.
- In the context of the specific assumptions (**Section 4.1**), the history of regulation, and the environmental setting, the ITPR team is of the view that the submergence of the CLA does present a low risk of adverse environmental outcomes for surface water and groundwater and that the approach is consistent with previous regulatory directions and broader principles of environmental protection, including the GED.
- Future monitoring and verification of the environmental performance is considered to be a key tenet of sound environmental management. The consolidated leached ash technical risk assessment (CLARA) provides the overall monitoring principles which the ITPR team considers appropriate. It is understood that specific details on the future monitoring requirements, trigger levels, and contingency actions are to be prepared prior to the submergence of the CLA. The ITPR team emphasises that an appropriately detailed water management plan as proposed should be developed and implemented so as to provide a robust framework for future environmental management of the CLA.

Refer to **Appendix A** for IPR letter.

3 General Environmental Duty

The approach used in the CLA technical assessment considers the principles of environment protection in accordance with the Environment Protection Act (2017). It provides details on the measures adopted by Alcoa which have enabled compliance with its GED by using industry best practice to achieve minimal risks of harm to human health and the environment, as far as reasonably practicable.

3.1 General Environmental Duty

The foundation of the Environment Protection Act (2017) and Environment Protection Amendment Act (2018) is the GED which requires individuals and industry to understand the risks associated with activities and minimise risk of harm to human health and the environment. The process of risk assessment assesses the chance of harm occurring, either qualitatively or quantitatively, and what the potential impacts could be to human health and the environment. A state of knowledge is developed of the risks and how they can be managed, in association with relevant regulatory guidance. The understanding of the risks enables controls that can be put in place to eliminate or minimise the risks that are reasonably practicable and are proportionate to the risk.

EPA Victoria Publication 1741.1 outlines the principles and objectives of the GED for industry and has been used by Alcoa, amongst other applicable guidance documents, to understand and demonstrate the measures that have been adopted and the framework followed to comply with the GED. This is principally associated with the activity of submerging the covered CLA material during the filling of the mine pit and development of the mine water body.

The following steps describe the approach used to demonstrate compliance with the GED:

- Undertaking appropriate technical studies related to submerging the CLA area, informed by Alcoa's extensive experience with the site – **Section 5**, **Section 6**, **Section 7**, **Section 8**, and **Section 9**;
- The application of a risk assessment process that will identify risks (based on the ERR risk assessment framework) including consideration of the consequence and likelihood associated with each risk – **Section 10**;
- Determining relevant performance objectives, controls and an appropriate level of monitoring associated with each identified risk, and commensurate of the level of each risk – **Section 4**, **Section 10**;
- The engagement of qualified and experienced technical expert consultants (EHS Support) to undertake the relevant technical studies;
- Being informed by previous technical studies completed in 2017 as part of the draft Mine Rehabilitation and Closure Plan (EHS Support, 2017);
- Being informed by ERR/EPA feedback related to the consolidated leached ash both in 2017, and in more recent 2021/2022 discussions with both ERR and the EPA – **Appendix B**;
- Completion of expert Independent Peer Review (BlueSphere) of the relevant technical studies and risk assessment – **Section 2**; and
- Implementing appropriate controls and monitoring proportionate with risks identified in the above – **Section 10**.

The approach and framework detailed above has allowed Alcoa to identify and understand all relevant risks to human health or the environment (state of knowledge), and also allowed Alcoa to minimise risks and meet its GED, so far as reasonably practicable.

4 Interim Water Quality Performance Targets

Dredged and dried leached ash has historically been placed into the former open cut coal mine in accordance with the Mine Work Plan endorsed by ERR in September 2011. Alcoa has considered the role of the Environment Protection Act (2017) in defining appropriate **interim** water quality performance targets (WQPT) for the purpose of this technical and risk assessment of the CLA area.

Since August 2015 groundwater recovery (and rainfall runoff) has slowly contributed to the development of the water body within the mine pit. A groundwater pumping test approved by Southern Rural Water (SRW) also contributed 671 ML of groundwater between May and December 2021. The mine water body itself is considered to be a constructed artificial surface water feature that enables the mine pit to meet the long term safe, stable, and sustainable landform objective of the draft MRCP. Clause 13 (2) of the ERS states that environmental values do not apply to waters in constructed artificial features, however it is acknowledged that future performance targets will be set for the protection of potential receptors in the surrounding catchment and will be aligned with the principles outlined in the GED.

A framework has been used to develop the approach to derive interim WQPTs associated with the catchment immediately surrounding the CLA area which includes the mine water body and groundwater within the Fill material and local Demons Bluff Formation (DBF) and Boonah Formation (BF). The framework derives WQPTs using water quality datasets to calculate an appropriate percentile value for each target. The main objective of this approach is to derive interim WQPTs during the activity of submerging the CLA. This is specifically to determine whether the process of submerging the CLA has any adverse impact on these potential receptors.

It is important to note that the long term (final) WQPTs for the mine water body have not been determined at this time as the mine water body filling strategy has not been finalised. Interim WQPTs have been developed and are included within this assessment. Final WQPTs are expected to be included as part of the MRCP finalisation.

The interim WQPTs presented here are complimentary to natural background water quality with the exception of boron which is discussed in greater detail below. This framework also considers technical feedback received from the EPA in relation to WQPTs for the mine pit water body and localised groundwater within the surrounding fill material, DBF and BF. Based on the direction provided by Department of Environment, Land, Water and Planning (DELWP) to Alcoa in 2016/2017 (refer to 2017 draft Mine Rehabilitation and Closure Plan [MRCP]; EHS Support, 2017) the mine pit water body is not intended to provide environmental values such as recreational uses and flora/fauna habitat support which are not complimentary to the local catchment. The water body does however have the future potential to provide non-contact recreational aesthetic enjoyment[4] such as visual appearance and bird watching from the surrounding Anglesea Heath, which will be further evaluated within the final MRCP.

[4] Reference: NHMRC – Guidelines for managing risk in recreational water, Designation of Recreational Uses

4.1 Environmental Legislation

A detailed review of the Environment Protection Act (2017) and the associated Regulations and ERS has been conducted in relation to the mine pit water body and CLA area and the surrounding catchment. The review has enabled an evaluation of how the legislation would apply to the CLA area and the mine pit water body and which environmental values are relevant for protection.

The Environment Protection Act (1970) was superseded by the Environment Protection Act (2017) ("new Act"), which came into force on 1 July 2021. The GED is at the centre of the new Act and applies to all Victorians. The GED requires that the entity engaging in an activity must reduce the risk of harm:

> *"A person engaging in an activity that may give rise to risks of harm to human health or the environment from pollution or waste must minimise those risks, as far as reasonably practicable5."*
>
> *Subordinate legislation is the group of tools that support the new Act, which include Regulations and the ERS. Under the new Act, the previous State Environment Protection Policies (SEPPs) are replaced by the ERS. The purpose of the ERS is to support the protection of human health and the environment from pollution and waste by providing benchmarks to be used to assess and report on environmental conditions in the whole or any part of Victoria.*

Part 5 (Water) of the ERS lists the environmental values of water environments in Victoria and describes the environmental quality that is needed to achieve and maintain these values. The environmental values of waters (both surface water and groundwater) are defined in Table 5.1 of Part 5, Division 1 of the ERS. Applicable protected environmental values for surface water, and each groundwater segment in the Anglesea area, are relevant for the Inland segment Central Foothills and Coastal Plains, as specified in the ERS.

As discussed in the ERS guidelines (EPA Victoria Publication 1992[6],[7]), an environmental value may not apply to groundwater or surface water if the background water quality exceeds the relevant objective and as a result the environmental value is precluded (cannot be achieved or maintained):

> *"Circumstances where environmental values are not recognised in the ERS still must be managed in accordance with the general environmental duty (GED). This means that a person must still take reasonably practicable measures to minimise risks from pollution and waste to the environment or human health, even where environmental values may not apply in the ERS".*

Under these circumstances, the background water quality level is the objective for the indicator because the background water quality better protects the environmental values[8][9].

[5] Quoted from: Industry Guidance: Supporting you to comply with the general environmental duty EPA Victoria Publication 1741.1 published October 2020, page 1
[6] Division 2 – Groundwater, Section 15 2(c) page 19;
[7] Division 3 – Surface water, Section 18 (3) page 25
[8] Division 2 – Groundwater, Section 16 2(b) page 19/20
[9] Division 3 – Surface Water, Section 19 2 (b) page 28

Segments for surface water are described in Clause 17 of the ERS. The site falls within the Central Foothills and Coastal Plains Segment (1a(iv)).

The protected environmental values for the Central Foothills and Coastal Plains are listed in Table 5.5, Clause 18 of the ERS and include:

- Water dependant ecosystems and species (slightly to moderately modified);
- Agriculture and irrigation;
- Human Consumption of Aquatic Foods;
- Industrial and commercial;
- Water based recreation (includes primary, secondary, and non-contact[10] aesthetic enjoyment);
- Buildings and structures; and
- Traditional Owner cultural values.

Segments for groundwater are described in Table 5.2, Clause 14 of the ERS. The DBF and BF[11] in the vicinity of the mine pit water body and CLA area is mostly dry, however beneath the former power station this aquifer is saturated. Based on the groundwater quality beneath the power station (EHS Support 2021b) the adopted segment classification for the DBF and BF is Segment B. Segment B is based on a total dissolved solids (TDS) concentration range of 1,201 to 3,100 mg/L. The segment classification of the Upper Eastern View Formation (UEVF) is also Segment B, which agrees with previous classifications (Coffey, 2015; GHD, 2013).

The protected environmental values for Segment B groundwater are listed in Table 5.3, Clause 15 of the ERS and include:

- Water dependant ecosystems and species;
- Potable mineral water supply;
- Agriculture and irrigation (irrigation and stock watering);
- Water based recreation (includes non-contact[12] aesthetic enjoyment);
- Industrial and commercial;
- Buildings and structures;
- Traditional Owner cultural values; and
- Geothermal properties.

The area is currently zoned as a special use zone (SUZ1) Schedule 1 under the Mine (Aluminium Agreement) Act 1961[13]. Future industrial or commercial use is possible and has been presented in concept as the development of a safe, stable, and sustainable landform and water body with associated tourist facilities.

Environmental values that could potentially be realised in both groundwater and surface water are discussed further in **Table 4-1** and **Table 4-2** below together with receptors, migration, and exposure pathways.

[10] NHMRC (2008) Guidelines for managing risks to recreational water
[11] Collectively the Demons Bluff Formation and the underlying Boonah Formation (DBF and BF), were formerly referred to as the Demons Bluff Group
[12] NHMRC (2008) Guidelines for managing risks to recreational water
[13] Mines (Aluminium Agreement) Act 1961 No. 6829 of 1961 Authorised Version incorporating amendments as at 30 November 2011 - an agreement between the Victorian government and Alcoa of Australia to allow the establishment and operation of the Anglesea mine.

Table 4-1 Environmental Values of Groundwater, Potential Receptors, and Migration and Exposure Pathways

Environmental Value	Potential Existing and Future Receptors		Potential Migration and Exposure Pathways
	DBF and BF	Off-site	
Water dependent ecosystems (slightly to moderately modified)	**Yes** (in the long-term) – Currently the DBF/BF lithological unit surrounding the water body is dry; however, it is acknowledged that the DBF/BF will become saturated in the future, the hydraulic connectivity between the water body and the DBF/BF will be established, and this environmental value will be realised. Preliminary analytical modelling has predicted that outward groundwater flow from the water body will be short-lived before the water body becomes a discharge feature.	**Yes** – The surrounding surface water catchment includes Salt Creek, Upper Anglesea, and Lower Anglesea River. There is no hydraulic connectivity between the DBF and BF and surface water, however there will be future connectivity between the water body and off-site groundwater within the DBF and BF.	**On-site:** Potential migration of contaminants from the CLA area (when submerged) and the water body into the developing groundwater body within the DBF and BF aquifer via groundwater flow. **Off-site:** During the filling of the water body there will be an outward flow from the water body into the DBF and BF aquifer, however once filling ceases the groundwater flow will reverse (refer to **Section 9** for potential timeframes based on numerical groundwater modelling).

Environmental Value	Potential Existing and Future Receptors		Potential Migration and Exposure Pathways
	DBF and BF	Off-site	
Potable mineral water supply	**No** – DBF and BF is not a recognised source of potable mineral water and the area is not a recognised source of potable mineral water as defined in the ERS. As such, this environmental value is considered not to be relevant.	**No** – DBF and BF is not a recognised source of potable mineral water, and the area is not a recognised source of potable mineral water as defined in the ERS; as such, this environmental value is considered not to be relevant.	
Agriculture and irrigation (irrigation and stock watering	**No**	**No** – As agreed with ERR the water body is not intended for flora and fauna support and therefore agriculture and irrigation are also considered to be unsupported. Use of DBF and BF groundwater is unlikely due to low yield and quality. These environmental values are not considered supported or relevant.	
Water based recreation (primary, secondary, and aesthetic)	**No**	**Yes** (in part) – The upper catchment is naturally acidic with low pH and elevated soluble metals; however, Anglesea Heath does provide aesthetic enjoyment. The Lower Anglesea River does provide secondary and aesthetic contact and enjoyment for the majority of the time, however, primary contact recreation is not recommended by the Surf Coast Shire (advisory signs are in place) due to the regular naturally occurring low pH of the River. During high flows from the upper catchment the Lower Anglesea River can be closed to recreation (primary and secondary) but aesthetic enjoyment is still recognised.	
Industrial and commercial use	**Yes** – The area is currently zoned as a special use zone (SUZ1). Future industrial or commercial use is possible and has been presented in concept as the development of a safe and stable landform and water body with associated tourist facilities.	**Unlikely** – The area is currently zoned as a special use zone (SUZ1). Future industrial or commercial use is possible and has been presented in concept as the development of a safe and stable landform and water body with associated tourist facilities. Use of DBF and BF groundwater is unlikely due to low yield, quality, and the availability of reticulated water locally.	

Environmental Value	Potential Existing and Future Receptors		Potential Migration and Exposure Pathways
	DBF and BF	Off-site	
Buildings and Structures	**Yes** – Buildings that proposed to intersect the groundwater will need to be resistant to corrosion.	**Yes** – Buildings (concrete and steel footings/foundations) that proposed to intersect the groundwater will need to be resistant to corrosion.	
Traditional Owner cultural values	Refer to comments under Off-site column to the right.	**Yes** – No specific Traditional Owner cultural values have been determined in discussions with the local Traditional Owner Wadawurrung representatives to date, however Alcoa has proposed that protection of any water (surface or ground) dependent eco-systems including the Anglesea River may also ensure the protection of Traditional Owner cultural values related to ground water and surface water in the area. Refer to Water dependent ecosystems (above) which are based on the natural or background levels.	
Geothermal properties	**No** – Groundwater within the DBF and BF has been measured as less than 30 degrees Celsius, therefore, this environmental value is not considered to be relevant.	**No** – Groundwater within the DBF and BF has been measured as less than 30 degrees Celsius, therefore, this environmental value is not considered to be relevant.	

Table 4-2 Environmental Values of Surface Water, Potential Receptors, and Migration and Exposure Pathways

Environmental Value	Potential Existing and Future Receptors		Potential Migration and Exposure Pathways
	Water Body	Off-site	
Water dependent ecosystems (slightly to moderately modified)	**Yes** – It is possible that ecosystems could develop in the water body which are similar to the surrounding naturally acidic catchment.	**Yes** – The surrounding surface water catchment includes Salt Creek, Upper Anglesea, and Lower Anglesea River. There is no hydraulic connectivity between the water body and surface water.	**On-site:** Potential migration of CLA porewater through Fill Material to the water body and potentially affecting land and air-based fauna. **Off-site:** Potential migration of contaminants from the water body by land and air-based fauna.
Human Consumption after appropriate treatment and human consumption of aquatic foods	**No** – The water body is an artificial constructed feature, and this environmental value is unlikely to be realised on-site in the future.	**No** – The natural catchment is acidic with low pH and elevated metals, and this environmental value is unlikely to be realised on-site in the future.	
Agriculture and irrigation	**No.**	**No** – As agreed with ERR the water body is not intended for flora and fauna support that is not consistent with background and therefore agriculture and irrigation are also considered to be unsupported. Use of DBF and BF groundwater is unlikely due to low yield and quality. These environmental values are not considered supported or relevant.	
Industrial and commercial use	**Unlikely** – This environmental value is possible, although water quality would have to be suitable for future proposed uses. Use is unlikely due to quality and the availability of reticulated water locally.	**Unlikely** – This environmental value is possible although water quality would have to be suitable for future proposed uses. Use is unlikely due to quality and the availability of reticulated water locally.	

Environmental Value	Potential Existing and Future Receptors		Potential Migration and Exposure Pathways
	Water Body	Off-site	
Water based recreation (primary, secondary, and aesthetic)	**No** – Water body is not intended to provide environmental values such as recreational uses, however does have the potential for aesthetic enjoyment.	**Yes (in part)** – The upper catchment is naturally acidic with low pH and elevated soluble metals, however Anglesea Heath does provide aesthetic enjoyment. The Lower Anglesea River does provide primary, secondary, and aesthetic contact and enjoyment for the majority of the time, however primary contact recreation is not recommended by the Surf Coast Shire (advisory signs are in place) due to the regular naturally occurring low pH of the River. During high flows from the upper catchment the Lower Anglesea River can be closed to recreation (primary and secondary) but aesthetic enjoyment is still recognised.	
Buildings and Structures	**Yes** – Buildings that proposed to intersect the groundwater will need to be resistant to corrosion.	**Yes** – Buildings (concrete and steel footings/foundations) that proposed to intersect the groundwater will need to be resistant to corrosion.	
Traditional Owner cultural values	Refer to comments under Off-site column to the left.	**Yes** – No specific Traditional Owner cultural values have been determined in discussions with the local Traditional Owner Wadawurrung representatives to date, however Alcoa has proposed that protection of any water (surface or ground) dependent eco-systems including the Anglesea River may also ensure the protection of Traditional Owner cultural values related to ground water and surface water in the area. Refer to Water dependent ecosystems (above) which are based on the natural or background levels.	

Alcoa consider that the following environmental values are not relevant:

- Potable mineral water supply (groundwater);
- Water based recreation (primary and secondary), both surface water and groundwater;
- Agriculture and irrigation (irrigation and stock watering) from both surface water and groundwater; and
- Geothermal properties (groundwater).

The consideration of whether an environmental value is relevant or not has been based on the availability of reticulated water and the quality and yield of groundwater in shallow aquifers (DBF/BF).

The DBF and BF surrounding the water body is partially saturated, however over time it will achieve a steady-state elevation. Based on the outcomes of the numerical modelling, particles of water are not expected to migrate more than a few metres from their source (as the water body acts as a sink under steady-state conditions). The hydrogeological characteristics of the shallow aquifers align with the low yielding definition from EPA publication 1992 page 52, 'In groundwater, an environmental value may not apply when there is insufficient aquifer yield to sustain the environmental value.' Aquifer yield is represented by hydraulic conductivity, which is a measure of permeability. The average permeability (Kxy) across all aquifer tests within the DBF and BF was $7.8x10^{-4}$ m/d. This is presented in EHS Support (2022) and has been used in the calibrated numerical modelling report. The permeability of an aquifer defines the potential rate of flow through a porous media. For the purpose of Clause 15(2)(a) of the Environment Reference Standard, insufficient aquifer yield can be considered as any porous media with a hydraulic conductivity less than 0.0001 m/day. This has been demonstrated via measurement of the aquifer properties and consideration of the factors described above.

The DBF and BF is also not potable mineral water as the catchment does not have any mineral springs and is not known to be a source of mineral water. Natural groundwater quality does not support a source of safe drinking water. As per example on EPA Publication 1992, page 75; The use of groundwater for potable mineral water supply was not considered relevant given that the investigation area was not located in a mineral spring district (Department of Minerals and Energy (1981), Groundwater Resources Map, 1981, 1:1,000,000 scale).

The area does not have any documented geothermal properties.

The ERS definition of potable mineral water is "groundwater that is safe to drink and in its natural state contains carbon dioxide and other soluble matter in sufficient concentration to cause effervescence". Shallow groundwater in the vicinity of the site is not a recognised source of potable mineral water, and the site is not located in a recognised mineral water area; as such, this environmental value is considered not to be relevant.

The mine pit water body is not intended to provide environmental values such as direct contact recreational uses, based on the direction provided by Department of Environment, Land, Water and Planning (DELWP) to Alcoa in 2016/2017 (refer to 2017 draft Mine Rehabilitation and Closure Plan [MRCP]; EHS Support, 2017); therefore, this environmental value is considered not to be relevant.

As agreed with ERR the water body is not intended for flora and fauna support that is not consistent with background and therefore agriculture and irrigation are also considered to be unsupported; therefore, these environmental values are not considered supported or relevant.

The site is located within an area of known potential for geothermal energy resources at depth (greater than 300 m depth), however the temperature of groundwater in close vicinity to the site has been measured as less than 30 degrees Celsius (an indicator as stipulated in the ERS); as such, this environmental value is not considered to be relevant.

4.1.1 Registered Bore Search

A search for registered groundwater users located within a 1,000 m radius of the site, using the DELWP Watering Measurement Information System (WMIS), was conducted on 19 April 2024. The results of this search identified 50 registered groundwater bores within a 1,000 m radius of the site all of which lie within the Alcoa lease area and are (or have been) used for the purposes of groundwater monitoring and/or groundwater abstraction. The search for the bores within the vicinity of the site is included in **Appendix C** for reference.

The search radius of 1,000 m was selected based on the outcomes of the fast fill scenario run using the regional numerical model. For this scenario 98 percent of the model realisations (147 of 150) indicate that all the particles migrating from the water body circumference into the surrounding aquifers, terminate within the mine lease area (<1,000 m) over the simulation period (2023 to 2066). All particles are also simulated to ultimately discharge to the water body because it forms a groundwater sink for all aquifer discharge in the long term.

4.2 Risk Assessment and Management

As described in **Section 10** and relevant to the activity, a detailed risk assessment has been completed for the activity of submerging of the CLA during the development of the mine pit water body. This section details the approach to the risk assessment, the potential hazards identified, the risk assessment matrix, and identifies appropriate controls for each risk.

In addition to the process described in **Section 10**, the source – pathway – receptor (SPR) approach has also been used to understand the potential modes of connectivity between the artificial mine pit water body and natural water features (refer **Table 4-3**).

Table 4-3 represents the relationship between the activity of submerging the CLA and the potential for leaching into the mine pit water body, and the interactions with relevant receptors. Linkages or pathways between these features are mostly permanent, with a potential temporary discharge from the water body to the surrounding fill material and natural DBF and BF aquifer (refer to **Section 9** for further detail) during the filling of the mine water body. The upper sands of the UEVF aquifer are omitted from this assessment as there is no connectivity between the UEVF (upper sands), the local DBF and BF groundwater, and the water body.

Table 4-3 Risk Assessment: Source – Pathway – Receptor

Source	Pathway	Receptor
CLA area	**Groundwater (fill material)** Pore-water within the CLA has a potential to migrate from the CLA area, through the clay-rich cover/berm into the surrounding fill material, when saturated. This pathway is only complete if the fill material is saturated between the CLA area and the water body.	Water Body
	Groundwater (fill material) Pore-water within the CLA has a potential to migrate from the CLA area, through the clay-rich cover/berm into the surrounding fill material, when saturated. If the filling of the water body has not been completed, then groundwater flow will be away from the water body towards the in-situ DBF and BF which is identified as a potential receptor of CLA pore-water. This pathway is only complete if the fill material is saturated between the CLA area and the DBF and BF groundwater.	DBF and BF groundwater user
Water Body	**Land** Animals drinking from the water body, can migrate between the artificial catchment of the water body and the surrounding natural catchment.	Ecosystems (flora and fauna)
	Air Birds using the water body for drinking and preening, can migrate between the artificial catchment of the water body and the surrounding natural catchment.	Ecosystems (fauna)

4.2.1 Protection of Maintenance of Ecosystems Environmental Value

The SPR assessment has been used to establish the pathways between sources and receptors. This process informs which water systems (or sources) are connected and whether the environmental values of natural water dependent ecosystems and species could be adversely affected from identified sources. For toxicants in water, the Anglesea water catchment lies within the Inland Segment Central Foothills and Coastal Plains[14]. Water dependent ecosystems and species within this segment are considered to be slightly to moderately modified. The indicators and objectives for this segment are provided in Table 5.8 of the ERS and for toxicants in water the percent (%) level of species protection (LOP) that must be used to determine the objectives is 95 percent.

Upper Anglesea River (monitoring location AV2) has been used as representative of surface water quality hydraulically up-gradient of the mine pit water body. In comparison to Salt Creek (monitoring location SV2), it contributes 75 percent of flow to the Lower Anglesea River during times of flow. Based on AV2 water quality central tendency values, pH provides 0 percent species LOP, aluminium provides 0 percent species LOP, boron protects 100 percent species, and zinc provides 20 percent species LOP. The existing background pH and concentrations of toxicants (aluminium and zinc) used to characterise the water quality within the catchment fall below the LOP required for this segment.

The mine pit water body is representative of a highly modified aquatic system and the percent LOP that must be used to determine the objectives is 90 percent. As there is no applicable segment for the mine pit water body there is no pH objective, however as the water body pH is comparable to natural catchment background, the potential level of species impact is likely to be similar.

Based on the comparison between the natural background toxicant concentrations of AV2 and the mine pit water body, AV2 aluminium and zinc concentrations provide lower LOP than the water body (Warne, 2018). Boron concentrations within the water body are less protective of species than AV2, however the only species potentially affected within the water body are diatom species, Cyclotella and Navicula[15] (ANZG, 2021). Due to the low pH (high acidity) and elevated electrical conductivity in background surface waters across the catchment (natural and artificial) it is unlikely that these diatom species are present[16]. Boron concentrations within the catchment (surface water and soils) are also discussed in EHS Support (2021c). The EHS Support (2021c) report concluded that in terms of species protection aluminium presented a much higher level of risk than boron. Boron toxicity tests to derive default guideline values were also conducted at pH 6.8 to 10 (ANZG, 2021). This pH range was used as the highest level of adsorption is observed at pH 7.5 to 9 (Australian and New Zealand Environment and Conservation Council & Agriculture and Resource Management Council of Australia and New Zealand [ANZECC/ARMCANZ] 2000 and WHO 1998). At low pH boron adsorption is expected to be lower and therefore boron concentrations which are protective of aquatic ecosystems are anticipated to higher than the default toxicant guideline values; however, it is accepted that the boron concentrations considered within EHS Support (2021c) are lower than the interim WQPTs values, particularly for the DBF and BF groundwater and that this groundwater quality data is associated with the power station monitoring network and not in the vicinity of the CLA area. Further future site-specific risk assessment is therefore proposed to assess the potential

[14] Division 2 – Groundwater, Section 17 1(a, iv) page 22.

[15] Cyclotella and Navicula. Cyclotella sp. Are both known to prefer circum-neutral to alkaline waters, pH 6.5 to 8.6 and pH 7.2 to 7.8 respectively and low concentrations of electrolytes, 92-332 uS/cm. The use of Cyclotella and Navicula in limnological investigations of acidic waters, should be approached with caution. Reference - https://diatoms.org/species/

risks to ecological receptors from boron sources (in addition to the CLA area). Additional risk assessment will be conducted as part of the MCRP finalisation.

This approach is considered to be consistent with the ongoing and accepted management of the surrounding naturally occurring surface water systems by the local authorities and regulators which include: DELWP; Corangamite Catchment Management Authority (CCMA); and the Surf Coast Shire.

The following sections provide a discussion on the natural background water quality within Salt Creek (monitoring location, SV2), Marshy Creek/Upper Anglesea River (monitoring location, AV2), DBF and BF, and the UEVF (upper sands), together with the artificially constructed mine water body water quality.

4.3 Catchment Surface Water and Groundwater Quality

The local catchment surrounding the mine pit water body comprises the following natural surface water and groundwater systems:

- Surface Water:
  - Salt Creek (and tributaries);
  - Marshy Creek/Upper Anglesea River (and tributaries); and
  - Lower Anglesea River.
- Groundwater:
  - Demons Bluff Formation and Boonah Formation (DBF and BF).

The Alluvial Swamp Aquifer (ASA) and UEVF (upper sands) groundwater are not hydraulically connected to the mine pit water body and are therefore not identified as potential receptors for the purposes of this risk assessment. Further detail on the local hydrogeology is described in EHS Support (2022).

The Water Body Filling Strategy has not finalised a source of water. There is no current agreement with, or direction from, DELWP (now DEECA) for future engineered connection between the natural surface water systems (i.e., Salt Creek) and the mine pit water body; as a result, the mine pit water body will not be directly connected to the Anglesea River catchment consistent with previous discussions with DELWP and with no engineered outlet or spillway (**Table 10-6**). Water also cannot move from the water body into the UEVF (upper sands), as an upward hydraulic gradient exists between the UEVF and the water body. During the 6-month UEVF (lower sands) pumping test, the vertical hydraulic gradient was significant, with a 65 m head difference between the pumped bore (i.e., UEVF lower sands) and the overlying aquifer units and no drawdown or change in trend was observed in any overlying units (including those immediately overlying the pumped unit). This gives an indication on the competency of the clay and coal layers between the thin upper sands of the UEVF. The DBF and BF aquifers are desaturated in the vicinity of the mine pit water body, however the DBF and BF aquifer is saturated in the vicinity of the former power station (**Figure 1**, attached). Groundwater quality for the DBF and BF beneath the former power station area is discussed in detail below (**Section 4.3**) together with the mine pit water body quality (**Section 4.4**).

All water analyses in the following tables are reported for dissolved species concentrations.

Table 4-4 (**Table 1**, attached) and **Table 4-5** (**Table 2**, attached) provide the water quality summary statistics from the Upper Anglesea River (or Marshy Creek) and Salt Creek during the period 1999 to 2021. Dissolved aluminium, boron, iron, and zinc within the Upper Anglesea River (monitoring location AV2) are generally elevated and the pH is usually less than pH 3.5 (net acidic). Dissolved aluminium, boron, iron, and zinc within Salt Creek (monitoring location SV2) are also observed to be elevated and the pH is usually less than pH 3.8; however, higher pH is observed in the upper reaches.

Table 4-4 Upper Anglesea River – Surface Water Quality Summary, 2000 to 2021

Analyte	Units	Upper Anglesea River/Marshy Creek (AV2)						Number of Samples
		Mean	Median	Min	Max	10th Percentile	90th Percentile	
pH	S.U.	2.93	2.76	2.69	3.74	2.70	-	10

Table Notes:
mg/L = milligrams per litre
NR = Not Recorded

The UEVF (upper sands) groundwater is moderately acidic and may also contain potential acidity. The UEVF (upper sands) groundwater is anoxic and in the presence of oxygen, acidity may be generated from the oxidation of ferrous iron to ferric iron and the hydrolysis of aluminium and manganese.

In the vicinity of the mine, the DBF and BF is largely unsaturated as the mine pit acts as a discharge point, meaning there is no groundwater quality data in this area; furthermore, where the mine has progressively been rehabilitated (i.e., overburden placed back into formation), the water quality of monitoring bores in this re-worked material is not truly reflective of the natural undisturbed DBF and BF.

Representative groundwater quality has been sourced from groundwater monitoring bores in the vicinity of the power station site (**Figure 1**, attached). **Table 4-7** (**Table 4**, attached) presents the water quality summary statistics from the DBF and BF groundwater during the period 2021 to 2022.

Table 4-7 DBF and BF (overburden/fill material)[17] – Groundwater Water Quality Summary 2021 to 2022

Analyte	Units	Mean	Median	Min	Max	10th Percentile	90th Percentile	Number of Samples
pH	S.U.	6.05	6.12	3.54	7.32	5.46	-	20
TDS	mg/L	2,483	2,495	1,510	3,320	-	3,039	20

Table Notes:
S.U. = standard units
mg/L = milligrams per litre

4.4 Current Water Body Water Quality

Surface water has collected within the low point of the mine pit and consists of rainwater, surface water runoff and groundwater pumping test discharge from the UEVF (lower sands).

The current water quality of the mine pit water body is characterised by elevated acidity (low pH), aluminium, boron, iron, and zinc (**Table 4-8** and **Table 5** [attached]), however these are generally lower in concentration within the mine pit water body (better quality) in comparison to the surrounding catchment. Boron is historically reported at higher concentrations within the mine water body; this is likely attributed to the historical dissolution of boron from coal fragments within the fill (overburden) material. Analytical results from in-situ coal samples collected in 2016 for the draft MRCP are provided as **Table 6** (attached).

Table 4-8 Mine Water Body Quality Summary 2021 to 2022

Analyte	Units	Mean	Median	Min	Max	10th Percentile	90th Percentile	Number of Samples
pH	S.U.	3.56	3.57	3.44	5.96	3.48	-	17
TDS	mg/L	1,715	1,680	1,500	2,470	-	2,004	17
Aluminium	mg/L	3.41	4.27	0.22	5.50	-	5.32	12
Boron	mg/L	1.14	1.22	0.32	2.05	-	1.46	12
Iron	mg/L	4.75	4.23	0.91	87.80	-	11.49	12
Manganese	mg/L	-		0.56	0.56	-	-	1
Zinc	mg/L	0.24	0.21	0.16	0.58	-	0.38	7

Table Notes:
S.U. = standard units
mg/L = milligrams per litre

[17] Well location: DBG MB4 and DBG MB6

4.5 Consolidated Leached Ash Porewater Quality

The 90th percentile leachable fraction values for aluminium, boron, iron, and zinc have also been provided for the CLA material (**Table 4-9**). The values include the leachable fraction analyses for samples collected from locations ADBH01 (two samples), ADBH02, ADBH03, ADBH04, ADBH05, ADBH06, and ADBH08 during the September 2021 field program (**Figure 6**, attached).

Table 4-9 Consolidated Leached Ash – Leachable Fraction (90th Percentile)

Analyte	Units	90th Percentile	
		pH 2.9	De-ionised Water
Aluminium	mg/L	17.1	3.78
Boron	mg/L	10.5	5.33
Iron	mg/L	3.0	3.45
Manganese	mg/L	3.6	0.08
Zinc	mg/L	0.1	0.02

Table Notes:
mg/L = milligrams per litre
Note: pH and TDS are not reported for leachable fraction analysis
Limit of reporting for zinc @ pH 2.9 is 0.1 mg/L

4.5.1 Quality Assurance and Quality Control

All water quality samples, and analysis collected by EHS Support has been subject to quality control and assurance (QA/QC) requirements of AS4482.1 and National Environment Protection Measure (NEPM) Schedule B2 Guideline on Site Characterisation and relevant EPA Victoria guidelines. Any analytical services are performed by a National Association of Testing Authorities (NATA) accredited laboratory. Barwon Water collect surface water samples from the wider catchment. Prior to 2016, Tetra Tech Coffey (formerly Coffey) and Alcoa shared responsibility for site sample collection and analysis. It was acknowledged in the draft MRCP that any data collected and reported prior to 2009 has no accompanying QA/QC documentation.

4.6 Water Quality Comparison

A comparison of the 90th percentile values for aluminium, boron, iron, and zinc have been provided for the leachable fraction of CLA, DBF and BF, and the mine pit water body (**Table 4-10**). The comparison indicates that only boron and aluminium would be potentially identifiable in the water body and the DBF and BF groundwater if a direct discharge of CLA porewater occurred.

Table 4-10 Comparison of CLA pore-water, Water Body and DBF and BF Groundwater (90th Percentile)

Analyte	Units	90thPercentile		
		CLA leachable Fraction pH 2.9[18]	DBG MB6 (DBF&BF)	Mine Water Body
Aluminium	mg/L	17.1	1.41	5.32
Boron	mg/L	10.5	0.53	1.46
Iron	mg/L	3.0	87.12	11.49
Manganese	mg/L	3.6	0.96	-[19]
Zinc	mg/L	0.1	0.4	0.38

Table Notes:
mg/L = milligrams per litre
Note: pH and TDS are not reported for leachable fraction analysis

After considering the influence of the groundwater hydraulic regime in the vicinity of the CLA area (change over time of hydraulic gradient from the east to the west) and the additional effects of retardation, impacts from the CLA area are unlikely to be measurable in either the water body or the DBF and BF groundwater. This is further supported by the groundwater hydraulic and particle tracking assessment in **Section 9**.

4.7 Interim Water Quality Performance Targets

The water quality datasets for the mine pit water body and DBF and BF groundwater have been used to develop interim WQPTs. The interim WQPTs will provide an indication of any impacts from the CLA area as it is submerged during the filling of the mine pit water body.

For the CLA Technical Assessment, the derivation of interim WQPTs for the mine pit water body and DBF and BF groundwater will aid in the assessment of risk, related to:

1. Short term – The activity of submerging the CLA area and potential impacts from CLA porewater on the DBF and BF groundwater; and
2. Long term – The activity of submerging the CLA area and potential impacts from CLA porewater on the mine pit water body.

The interim WQPTs developed for the mine pit water body and DBF and BF groundwater are currently considered as interim. The final mine pit water body water quality is currently unknown as the source of water to fill the water body has not been finalised, however the future water quality will be complimentary to background water quality, with the possible exception of boron. Future WQPTs will be developed during the finalisation of the MRCP using the framework described.

[18] The leachable fraction at pH 2.9 has been selected for comparison as this pH is most comparable to the water body pH. Water body water is slowly saturating the surrounding fill material
[19] Only one sample from the mine water body has been analysed for manganese therefore 90th%ile value has not been calculated

The application of interim WQPTs and the final WQPTs will aid in the identification of any deterioration of environmental values and receptors as the water body filling strategy proceeds and the CLA area is inundated. As described in the sections above, the environmental values of the surrounding natural catchment must be protected. The risk to environmental values of water dependent ecosystems and species will be low and manageable using contingency measures which will be developed as part of the water body filling strategy. It is acknowledged that boron concentrations in the water body are elevated in comparison to the natural catchment and further site-specific risk assessment is proposed to assess the potential risks to ecological receptors from boron sources (in addition to the CLA area). Additional risk assessment will be conducted as part of the MCRP finalisation.

As part of the framework for developing interim WQPTs, a statistical approach has been adopted using percentile values. The 90th percentile has been used for aluminium, boron, iron, and zinc and the 10th percentile for pH. This approach has been discussed and agreed with EPA Victoria (EPA Victoria letter dated 2 September 2022).

The interim WQPTs for the mine pit water body and DBF and BF groundwater derived from 10th and 90th percentile values for pH, aluminium, boron, iron, and zinc are provided in **Table 4-11** and **Table 4-12**. The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZ Guidelines) toxicant default guideline values for the protection of aquatic ecosystems have also been provided for the 90 percent and 95 percent species LOP (where available).

Table 4-11 Interim Water Quality Performance Targets – Metals/Metalloids (90th Percentile)

Analyte	Units	DGV		90th Percentile	
		95% LOP Slightly to Moderately	90% LOP Highly Modified	DBF&BF	Mine Water Body
TDS	mg/L	-	-	3,039	2,004
Aluminium	mg/L	0.0008[20]		0.27	1.41
Boron	mg/L	0.94	1.5	0.53	1.46
Iron	mg/L	0.3[21]		30	87.12
Manganese	mg/L	1.9	2.5	0.96	-[22]
Zinc	mg/L	0.008	0.015[23]	0.4	0.38

Table Notes:
DGV = Derived Guideline value
mg/L = milligrams per litre

Table 4-12 Interim Water Quality Performance Targets – Catchment pH (10th Percentile)

Analyte	Units	DGV	10th Percentile	
		95% LOP slightly to moderately	DBF&BF	Mine Water Body
pH	S.U.	≥6.8 - ≤8	5.46	3.48

Table Notes:
S.U. = standard units

[20] For waters pH<6.5. actual pH range pH 4.5 to 6 used to derive aluminium DGV, unknown level of species protection
[21] Canadian guideline value
[22] Only one sample from the mine water body has been analysed for manganese therefore 90th%ile value has not been calculated
[23] Level of protection not pH specific

4.8 Conclusion

A framework has been used to develop interim WQPTs associated with the catchment immediately surrounding the CLA area. These receptors include the mine water body and groundwater within the Fill material and local DBF and BF. The framework for the risk-based assessment of groundwater that may be affected by water quality changes, as detailed in the National Environment Protection (Assessment of Site Contamination) Measure 1999 (NEPC, 2013), has been considered in the development of the interim WQPTs.

The framework derives WQPTs using water quality datasets to calculate an appropriate percentile value for each target. These datasets have been used to calculate the 10th percentile values for pH and 90th percentile values for aluminium, boron, iron, and zinc. The main objective of this approach is to derive interim WQPTs during the activity of submerging the CLA. This is specifically to determine whether the submerged CLA has any adverse impact on these potential receptors. These interim WQPTs are presented in **Table 4-11** and **Table 4-12**.

It is acknowledged that groundwater monitoring should be conducted in the vicinity of the CLA area to assess whether pore water migration from the CLA area is occurring. Sentinel wells located in proximity to the CLA area (within 5-10 m) were considered, however this was not considered practicable for the following reasons:

- Any new wells could only be installed during dry conditions, providing only a seasonal opportunity to do so during summer. This becomes more difficult as the water body elevation approaches the CLA area.
- The installation and decommissioning of wells prior to inundation could present a risk of creating additional water migration pathways after inundation.
- The process of inundation is potentially within a time period of two years, during which wells will need to be decommissioned prior to submergence. This does not provide an adequate time frame to collect a representative dataset as the formation surrounding the CLA saturates and the water quality takes time to equilibrate.
- The objective of these wells would be to validate any potential seepage from the CLA, and this can't occur if the area is submerged.
- Based on the SEEP/W model outcomes the formation is expected to remain unsaturated after inundation, meaning that there will be no groundwater quality to measure prior to any new wells needing to be decommissioned.

Existing groundwater monitoring wells in the vicinity of the CLA area (DBG MB4, DBG MB5, and DBG MB6) will therefore be used to monitor the potential risks of pore water migration from the CLA area into surrounding fill material during (and after) the inundation period. These wells are screened within the clay-rich fill material and DBF and BF. These locations have been part of the groundwater monitoring network surrounding the mine area since 2021 and will continue to be monitored as the CLA area is inundated by the water body. Due to their locations, they will remain even after the water body attains steady-state elevations, and are located well within the Alcoa mine specified area, therefore provide significant early warning of any issues relative to potential receptors.

Monitoring/sampling of the mine pit water body will be undertaken during the filling period and inundation period. Evaluation of the results against WQPT will be used to assess whether seepage is occurring from the CLA.

Note that that the long term WQPTs for the mine water body cannot be determined at this time as the mine water body filling strategy has not been finalised, these are expected to be included as part of the MRCP (when finalised). Note also that the mine pit water body is not intended to provide environmental values such as direct contact recreational uses (with the exception of aesthetic enjoyment), based on the direction provided by DELWP to Alcoa in 2016/2017 (refer to 2017 draft Mine Rehabilitation and Closure Plan [MRCP]; EHS Support, 2017).

It has also been demonstrated that the interim WQPTs presented here are complimentary to natural background water quality with the exception of boron. In comparison to the natural background water quality of the catchment, the water body has lower concentrations of aluminium, iron, and zinc. Boron concentrations in the water body are higher than natural background concentrations, however, as discussed in **Section 4.2**, aluminium is considered to be the primary risk driver and not boron. The DBF and BF in the vicinity of the mine pit is currently dry, however there is a potential that this part of the DBF and BF aquifer may become saturated as the mine pit water body develops.

5 Anglesea Ash History and Management

5.1 Alcoa Former Power Station

The former power station at Anglesea used coal from the former open cut brown coal mine (adjacent to the power station) to generate electricity for the aluminium smelting facility in Point Henry, Geelong. The power station started generating electricity in 1969 and closed in 2015. Approximately 1 million tonnes of brown coal was consumed by the power station each year (GHD, 2012). The ashing system was used to collect, convey, and dispose of the ash generated within the furnace and from the precipitators at the Alcoa Anglesea former power station. The coal at Anglesea contained on average between two to four percent ash which is a by-product of the coal combustion process. Some of the ash was collected in the furnace bottom hopper, while the fly ash was entrained in the flue gases. The fly ash comprised a greater proportion of the total ash. The electrostatic precipitators collected the fly ash from the gas stream before the atmospheric dispersal of gases via the stack. The bottom ash from the furnace was sluiced away by water from the ash tank and the fly ash was removed by a pneumatic system. The combined furnace ash and fly ash was then transported by the water sluices through piping to Ash Pond 1 (**Figure 5-1** and **Figure 1** [attached]).

Leached ash from Ash Pond 1 was periodically removed and dried. Ash Pond 1 was initially designed to be dredged once every five years during a plant shutdown. Alcoa changed to a 'finger excavating' process in the late 1990s where a section of the pond (a finger) was kept operational while one other 'finger' was cleared by excavation and then brought back online avoiding the need for plant shutdown. The two fingers are observed to the north of Ash Pond 1 in **Figure 5-1**. The dried excavated leached ash was then deposited in the mine pit and incorporated into the general overburden backfill process as per the Mine Work Plan endorsed by ERR September 2011 (**Figure 2**, attached). Note that Ash Pond 2 was never required to be used for ash management.

Figure 5-1 Ash Pond Drying Areas

5.2 Alcoa Former Open Cut Mine

The CLA area within the south-eastern corner of the former coal mine consists of the final dried leached ash that was progressively tipped by truck during operations, with the final material dredged and pumped after the closure of the power station during 2016. The leached ash was sourced from the ash drying cells and Ash Pond 1 within the power station area (**Figure 1**, attached) and was permitted to be placed within the mine in accordance with the Mine Work Plan endorsed by ERR in September 2011.

The CLA area lies between relative levels (RL) - 15 metres Australian Height Datum (mAHD) and -8 mAHD, at an average thickness of 4 m, and over a final area of approximately 4.6 ha.

The leached ash that was sourced from the drying cells next to Ash Pond 1 has a considerably lower moisture content than leached ash that was dredged and pumped from Ash Pond 1; however, this dried ash would have been leached and aged (just like ash dredged from Ash Pond 1) during the residence time in Ash Pond 1. The pumped and dredged leached ash was allowed to naturally dewater and consolidate to enable earthmoving machines to then cover the leached ash with clay-rich material. Dewatering occurred via a combination of evaporation, decanting into the water body and minor lateral seepage into the surrounding fill material (refer to further discussion in **Section 6.3.2**). In late 2016 and 2017 dried leached ash was consolidated together with the dredged leached ash into the area now known as the CLA area.

The CLA was encapsulated with at least 1 m of earth-moving machine compacted clay-rich fill material, typically in approximately 300 mm lifts allowing machine compaction in each lift. This material consists of clay, silt, and minor sand which limits recharge and provides a low permeability hydraulic separation from the developing mine water body (referred to hereafter as the water body)[24] that will develop in the mine pit as part of the closure plan. Covering of the CLA with the clay-rich material was completed in the first quarter of 2018.

Additional fill material re-deposited in the pit in the vicinity of the encapsulated leached ash consists of reworked sands, clays, and silts (**Figure 3** and **Figure 4**, attached). Locally the fill material displays similar permeability characteristics (on average less than $1x10^{-9}$ m/sec) to the CLA and clay-rich cover. At depth (approximately -40 mAHD) beneath the CLA layer is the horizon referred to the Basal Clay, which underlies the mined A Group coal seam and is approximately 1-2 m thick in this locality. This unit provides a horizontal hydraulic separation between the underlying UEVF and the overlying fill material.

Refer to **Section 6** and **Section 9** for additional characterisation on the CLA area materials and local geology, respectively.

[24] Surface water feature developing in the former open cut coal pit.

5.2.1 Consolidated Leached Ash Area Design Methodology

The CLA material will be inundated and submerged by the developing water body and will be submerged by at least 12 m of water, as proposed by the draft MRCP.

Alcoa recognises that EPA Victoria's Best Practice Environmental Management (BPEM) Publication Siting, design, operation, and rehabilitation of landfills (BPEM, 2015) is the source document for best practice management measures for landfills. The BPEM states that landfills must not be located below the regional water table, however the CLA area was not intended to be designed or designated as a traditional landfill or meet the requirements of the landfill BPEM, rather it was intended that leached ash would be deposited in the mine pit and incorporated into the general overburden backfill process as per the Mine Work Plan endorsed by ERR September 2011.

The BPEM also allows *'for an alternative risk-based design*', and this is the basis that Alcoa has developed the current 'design' of the CLA area and material cover.

For this assessment the best practice objectives of the BPEM have been referenced but not necessarily adopted for all standards. A risk-based approach has been adopted to demonstrate that the low permeability clay rich material surrounding the CLA is suitable to minimise and mitigate any risks that may arise from the CLA area.

The intention has been to provide for a low permeability clay-rich cover on top of the CLA area and low permeability fill material surrounding the area to contain the CLA and mitigate future risks. The CLA area it therefore surrounded by semi-engineered materials which have achieved the same objective as an engineered liner.

Key considerations in the placement and long-term management of CLA material that mitigate both short- and long-term risks include:

1. Leaching of Coal Combustion Ash (CCA) in the power station ash ponds.
2. Historical drying of leached ash in the finger excavating process.
3. The progressive dewatering and compaction (by earth moving machines) of the dredged leached ash.
4. Consolidation of dried and dredged leached ash into a final clearly defined CLA area.
5. The defined CLA area is bounded on three sides by the haul road and berm, both of which are constructed with clay-rich material derived from the DBF and BF overburden.
6. Covering the CLA with clay-rich material:
    a. Clay-rich material was laid in three, approximately 300 mm lifts by pushing the material out with dozers and track rolled for compaction; and
    b. Completed in a short period of time to prevent drying of the surface.
7. Confirmation of the placement of CLA, clay-rich cover by intrusive field investigation and sampling to demonstrate the spatial extent of CLA, clay-rich cover and associated permeability.
8. Sampling of the clay-rich cover material and surrounding material to confirm permeability of containment area confirming that the mean values for each material group were less than $1x10^{-9}$ m/sec.
9. Numerical modelling and particle tracking to determine any potential short- and long-term interaction of CLA with surface and groundwater.
10. Assessment of identified risks related to the environment including surface and groundwater, and considerate of interim water quality performance targets for both, while being mindful of background water quality.

Table 5-1 provides a summary of the placement methodology adopted for the clay-rich cover in comparison to BPEM standards.

Table 5-1 Clay-rich Cover Placement Methods

Clay Cover Placement	Units	BPEM Standard	Site Results
Number of lifts	n/a	Minimum of 4 for 1 m thick liner	3
Lift thickness	mm	<250 mm	approximately 350 mm
Placement Method	n/a	Appropriate equipment	Appropriate equipment
Lift Scarification	n/a	Yes	Yes
Clay Total Thickness	m	≥1 m	≥ 1 m
Clay Liner Finish	n/a	Smooth	Smooth with a low gradient to the south-west (towards water body)
Photo Evidence	n/a	Yes	Yes[25]

Figure 5-2 provides a conceptualisation of the design methodology for the CLA area (also refer to **Figure 5**, attached).

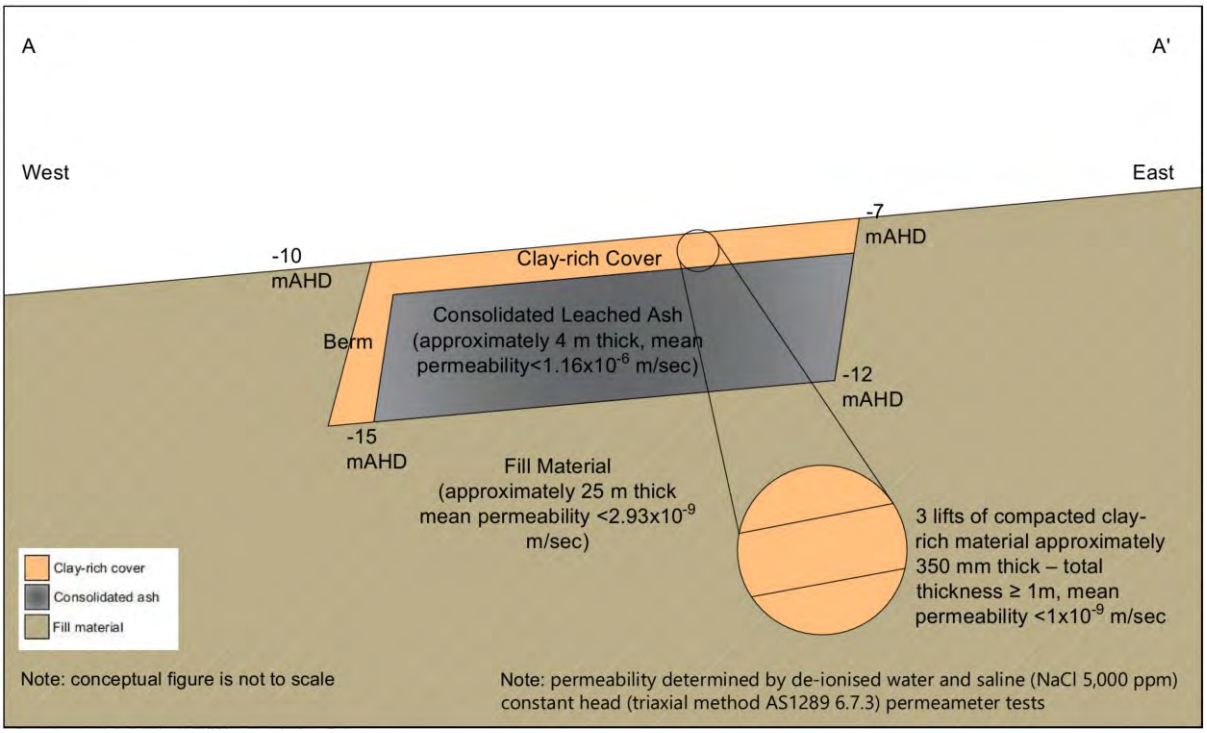

Figure 5-2 Consolidated Leached Ash Area – Conceptual Cross Section

[25] Refer to **Appendix D** CLA Site Photographs

On-going aftercare of the CLA area prior to being submerged includes weekly inspections to ensure unacceptable erosion of the clay-rich cover is not occurring, with any erosion repaired where required. In addition to the compacted clay-rich cover, the CLA area is bounded from the northwest to the east by the mine haul road. This haul road was progressively developed using the same clay-rich material as the CLA cover.

The road material has been compacted through the development and use of the haul road by heavy machinery. The road is also present through the full vertical profile of the fill material in this area of the mine pit, from approximately -40 mAHD (the base of the excavated coal horizon) to -7 mAHD (the current surface elevation). The berm (to the west of the CLA area) was also constructed using clay-rich material and the same placement methodology as the clay-rich cover. The berm was built in lifts and tracked by heavy earth-moving machinery and is wider at the base than the top.

Table 4 and **Table 9** (attached)provide a summary of permeability values measured from undisturbed samples collected in 2021 and 2022 from the following domain areas:

- Clay-rich cover;
- CLA;
- Fill material (to the south and beneath the CLA);
- Haul road (clay-rich material); and
- Berm (clay-rich material).

Field sampling in September 2021 and June/July 2022 was conducted to demonstrate that the CLA area is surrounded by at least 1m of clay-rich low permeability material. All sample holes through the clay-rich cover were re-plugged with bentonite and not remoulded clay.

Table 5-2 provides permeability characterisation of the clay-rich material used to form the cover over the CLA area.

Table 5-2 Clay-rich Layer Properties

Clay Properties	Units	BPEM Standard	Number of Tests	Site Results
Hydraulic Conductivity	m/sec	$<1x10^{-9}$	4	$2x10^{-9}$ to $2x10^{-10}$
Long-term permeation tests (5,000 ppm saline solution[26])	m/sec	$<1x10^{-9}$	5	$1x10^{-9}$ to $2x10^{-10}$

In addition to the clay-rich cover permeability characteristics, samples were also collected within the CLA and fill material (**Table 5-3**).

Table 5-3 Consolidated Leached Ash and Fill Material Properties

Domain Area	Units	Hydraulic Conductivity (de-ionised water)	Hydraulic Conductivity (5,000 ppm saline solution)
Consolidated Leached Ash	m/sec	$9x10^{-9}$ to $7x10^{-10}$ (7 samples)	Not conducted[27]
Fill material	m/sec	$6x10^{-8}$ to $9x10^{-11}$ (12 samples)	$4x10^{-8}$ to $8x10^{-11}$ (17 samples)

[26] A salinity of 5,000 ppm was agreed with BlueSphere (independent peer reviewer) prior to testing as this concentration is representative of the salinity of the CLA porewater

[27] Saline water permeameter tests were not conducted on CLA samples as this test method was only conducted on samples collected during 2022. Consolidated leached ash was not sampled during this event.

The geomean values for each material group were less than $1x10^{-9}$ m/sec. Refer to **Appendix E** for all laboratory analysis reports.

The values provided in **Table 5-2** and **Table 5-3** confirm the presence of low permeability materials (clay-rich cover and fill materials) which surround the CLA area and in addition includes the CLA. These values have also been used in the hydraulic modelling assessment (**Section 9**) which forms part of the overall CLA risk assessment. The outcome of the hydraulic modelling also demonstrates that the low permeability materials limit the migration of conservative constituents (such as boron and sulfate) from leached ash porewater to groundwater.

The placement method of the clay-rich cover together with the results of the intrusive site investigations demonstrate the effectiveness of the low permeability clay-rich material, including during any inundation and submerging of the CLA for both natural and fast fill mine water body filling strategies. These outcomes are also supported by hydraulic modelling.

The materials and placement methods have therefore met the objective and design criteria of limiting leached ash porewater migration from the CLA area in both the short and long term.

All testing and reporting is provided that support the above objective. This documentation has also been reviewed and verified by an independent peer reviewer (BlueSphere), refer to **Section 2** and **Appendix A**.

6 Anglesea Ash Characteristics

The by-product of using coal to fuel electricity generation at power stations is a combination of fly and bottom ash commonly called coal combustion residues, product, or CCA. Anglesea CCA is the product of the historical combustion of brown coal (or lignite) mined from the UEVF used to generate electricity at the former Alcoa Anglesea power station. A combination of the furnace (bottom ash) and electrostatic precipitated ash (fly ash) was produced from the combustion process. The proportions of bottom ash to fly ash can vary depending on the characteristics of the coal and the coal burning process but fly ash comprises the dominant portion (approximately 80 percent) in dry-bottom boiler furnaces and the Anglesea CCA (GHD, 2012). Fly ash comprises a very fine material usually consisting mostly of silica, calcium, aluminium, and iron. Bottom ash is coarser in texture and forms at the bottom of the furnace. Anglesea CCA can also have a small amount of sand which is an artefact from the open-cut coal mining activity. During the mining of coal, fill material would occasionally become entrained within the coal and remains after combustion in the bottom ash residue.

6.1 Ash Characterisation Studies – Historical

Historical characterisation of the Ash materials has been conducted by Alcoa and indicates that the combustion of Anglesea brown coal fly ash has produced a high calcium content ash. **Table 6-1** and **Figure 6-1** provide chemical testing of ash conducted by Alcoa (Beattie, 2003 and GHD, 2012). Concentrations of trace elements (antimony, cadmium, chromium [hexavalent], mercury, molybdenum selenium, silver, and tin) were analysed below 10 mg/kg. Arsenic, copper, lead, and vanadium concentrations were also reported less than 50 mg/kg. Trace elements that are reported as elevated (greater than 100 mg/kg) include barium, boron, manganese, nickel, and zinc.

Note that historical major ion concentrations for leached ash (ash samples recovered from ash ponds) are not available. Also, the minor ion concentrations reported by GHD (2012) are based on median concentrations reported between 2006 and 2011.

Table 6-1 Major Compound and Element Chemical Composition of Fly Ash prior to Mixture with Water – Analysed by Alcoa in 2002 (Beattie, 2003)

Major Compounds	% Dry Basis
Calcium oxide (CaO)	18.63
Sulfur trioxide (SO_3)	18.18
Magnesium oxide (MgO)	17.55
Silicon dioxide (SiO_2)	14.58
Iron (III) oxide (Fe_2O_3)	13.3
Aluminium oxide (Al_2O_3)	5.13
Sodium oxide (Na_2O)	2.65
Potassium oxide (K_2O)	0.19
Titanium dioxide (TiO_2)	0.09

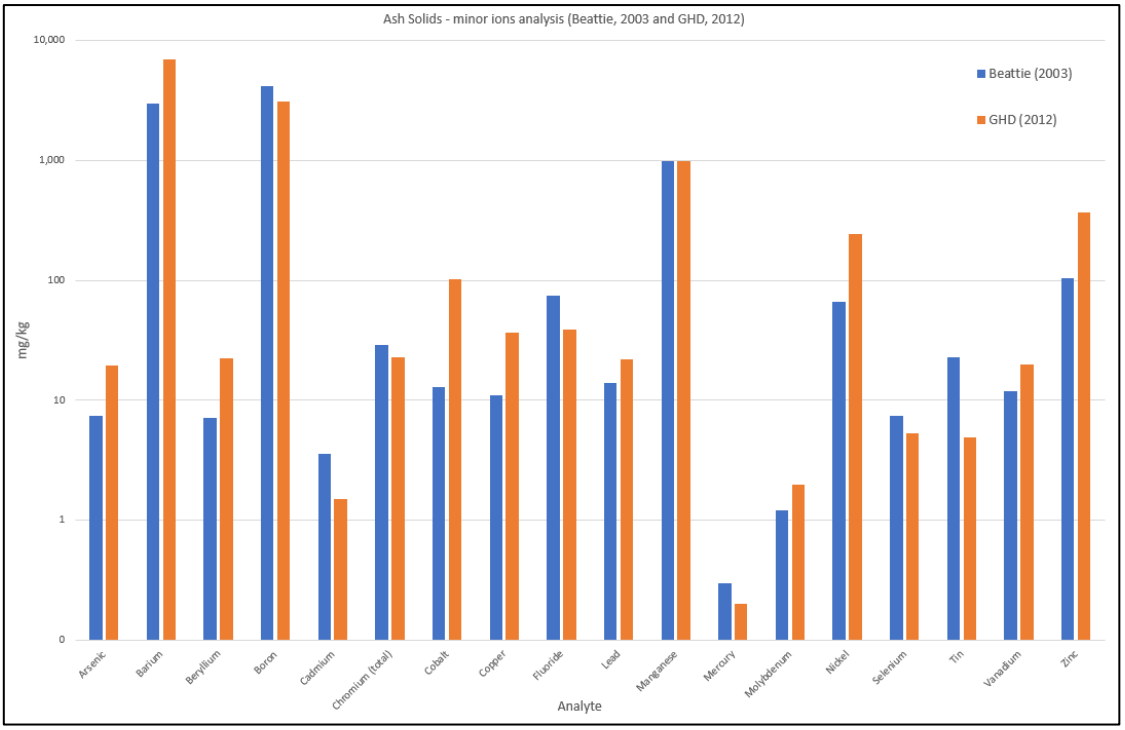

Figure 6-1 Minor Ions (Beattie, 2003 and GHD, 2012)

As shown in **Figure 6-2** and **Table 6-2**, the majority of analytes within the ash appear to have low leachability as demonstrated by the ash pond water quality. Most analytes are reported below the limit of reporting (based on the limit of reporting at the time of analysis). This is most likely due to the pH of the historical ash ponds, which is not conducive to the solubility of most metals and subsequent leaching from the ash. Total dissolved solids are elevated which is most likely due to the major ion concentrations.

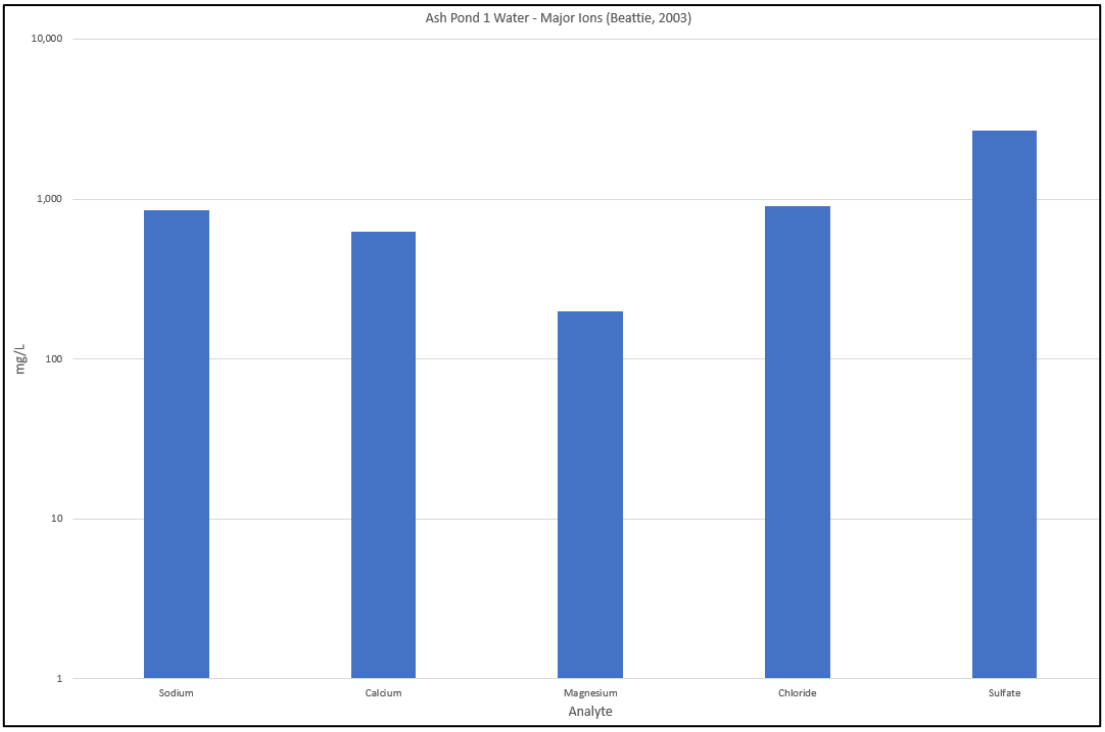

Figure 6-2 Ash Pond 1 Water – Major Ions (Beattie, 2003)

Table 6-2 Minor Ion Chemical Composition of Ash Pond 1 Effluent - Analysed by Alcoa in 1999 (Beattie, 2003)

Analyte	Ash Pond 1 Water Concentrations (mg/L)
Aluminium	<0.005
Arsenic	<0.005
Barium	0.061
Beryllium	<0.005
Boron	36
Cadmium	<0.005
Chromium	<0.005
Cobalt	<0.005
Copper	<0.005
Fluoride	<0.5
Iron	<0.1
Lead	<0.005
Manganese	0.1
Mercury	<0.001
Molybdenum	0.007
Nickel	<0.005
Selenium	0.006
Tin	<0.005
Vanadium	<0.005
Zinc	<0.005

On the basis of the historical testing (Beattie, 2003), the key constituents with potential to leach from the ash materials at high concentrations are limited to major ions (as total dissolved solids) and boron. The results are however dependent on the age of the leached ash and contact time with water in the ponds.

6.2 Ash Characterisation Study – 2016

Additional characterisation of ash solids and Ash Pond 1 water was conducted during 2016 for the development of the draft MRCP.

6.2.1 Field Sample Collection

Samples collected from Ash Pond 1 have been used to provide detailed chemical information on the characteristics of the ash material and ash pond water. Ash solid and aqueous samples were collected in June 2016 (**Table 6-3**).

Table 6-3 Solid and Aqueous Samples

Sample Location	Sample Type	Sample Analytical Test	Number of Sample Locations	Total Number of Samples
Ash Pond 1	Solid – Ash Pond 1	Solid characterisation and ash solid	3	3
	Surface water – Ash Pond 1 water	Water quality analysis and leachable fraction procedure	3	3

Figure 6-3 shows the approximate locations of where the samples were collected.

Figure 6-3 Ash Pond 1 Solid and Aqueous Locations

The solid and aqueous samples were subjected to a detailed solid and wet chemistry analytical schedule (**Table 6-4** and **Table 6-5**).

Table 6-4 Analytical Schedule for Solid Sampling

Analytical Group	Analytical Parameter
Laboratory analysis of major ions	Calcium, magnesium, sodium, potassium, sulfate, chloride, alkalinity (total, bicarbonate, and carbonate).
Laboratory analysis of minor ions	Fluoride.
Laboratory analysis (total) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, manganese, molybdenum, nickel, tin, lead, vanadium, zinc, and mercury.

Analytical Group	Analytical Parameter
Laboratory analysis (soluble) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, ferrous iron (dissolved), manganese, molybdenum, nickel, tin, lead, vanadium, zinc, and mercury.
Laboratory analysis physicochemical	Particle size distribution (ash solids only), moisture content, exchangeable cations, pH, total acidity, total organic carbon.
Laboratory analysis	pH (1:2) and electrical conductivity (1:2).
Laboratory analysis	Maximum Potential Acidity (MPA).
Laboratory analysis	Acid Neutralising Capacity (ANC).
Laboratory analysis	Net Acid Producing Potential (NAPP).
Laboratory analysis	Net Acid Generation (NAG).

Table 6-5 Analytical Schedule for Aqueous Sampling

Analytical Group	Analytical Parameter
Field parameters	pH, temperature, turbidity, electrical conductivity, dissolved oxygen, redox potential.
Laboratory measured 'field' parameters (where instrumentation is not available)	pH, turbidity, electrical conductivity, redox potential.
Laboratory analysis of major ions	Calcium, magnesium, sodium, potassium, sulfate, chloride, alkalinity (total, bicarbonate, and carbonate), total hardness, total dissolved solids.
Laboratory analysis of minor ions	Fluoride.
Laboratory analysis (total) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, manganese, molybdenum, nickel, tin, lead, vanadium, zinc, and mercury.
Laboratory analysis (dissolved) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, ferrous iron (dissolved), manganese, molybdenum, nickel, tin, lead, vanadium, zinc, and mercury.

A modified Australian Standard Leachate Procedure (ASLP) was also used to derive leachable fraction solutions from the batch mixing of Ash Pond 1 solids with Ash Pond 1 water.

6.2.2 Chemical Testing – Ash Solids and Leachable Fraction Analysis

As described earlier three samples of ash solids were collected from Ash Pond 1 and analysed for the constituents listed in **Table 6-4** above.

Two split samples of an ash solid sample (collected at Location 1, **Figure 6-3**) were used in a modified ASLP test which used a replicate sample of Ash Pond 1 water (collected at Location 3, **Figure 6-3**) as the reagent water. The resulting leachable fraction was then analysed using the same suite of analytical parameters used for other aqueous samples (**Table 6-5**).

The results of the ash solid sample analyses are provided in **Table 7** (attached).

The results of the ash pond water analyses are provided in **Table 8** (attached).

The results of the ash solid ASLP leachate analyses are provided in **Table 9** (attached).

6.2.2.1 Ash Solids – Physical Characteristics

The samples collected from within Ash Pond 1 are typically fine-grained with greater than 70 percent of particles reported between 2 to 60 µm (silt fraction). The ash pond samples display a variable cation exchange capacity, with Location 2 sample reporting 61.3 meq/100g and Location 3 reporting 14.1 meq/100g. Location 1 and 2 samples are dominated by exchangeable magnesium, in contrast to Location 3 which is low in exchangeable magnesium. All samples report low exchangeable sodium, potassium, and calcium (**Table 2**, attached). The fine-grained characteristics of the ash solids are likely to create a low hydraulic conductivity area when deposited in the former mine pit based on these results. The presence of silts and clays has the potential to provide attenuation in the form of sorption surfaces for metal cations and major ions (such as sodium, potassium, calcium, and magnesium).

6.2.2.2 Ash Solids – Ash Acid and Alkali Generating Characteristics

Several tests were conducted on the ash to characterise the acid-producing and acid neutralizing potential. Although the ash is an alkaline material there was a potential for the presence of coal fines within the ash. These tests included:

1. Total sulfur;
2. MPA;
3. ANC expressed as percentage calcium carbonate ($CaCO_3$) and kg of sulfuric acid (H_2SO_4) equivalents per tonne;
4. NAG at pH 4.5 and pH 7;
5. NAPP; and
6. Fizz rating.

Initial pH screening tests (field pH [pHF] – pH in deionised water and field oxidised pH [pHFOX] tests) were not undertaken on the samples to determine the degree of acidity. This was based on the historical geochemical characterisation of the ash and its anticipated alkaline nature.

The MPA can be estimated from the total sulfur content, although it is a conservative approach because it assumes all sulfur generates acidity under oxidising conditions. All the ash samples contained low amounts of sulfur (**Table 2**, attached). A conservative assessment of acidity potential using the sulfur concentrations estimates that the ash has a low potential acidity production.

ANC measures the amount of acid a sample can neutralise. The consumption of acidity by a sample is determined and expressed as kg H_2SO_4 equivalents/tonne. This reports the ability of a sample to neutralise (using its buffering capacity) any acidity generated. ANC is elevated in the ash solids, so NAPP is unlikely from the ash samples. The fizz rating for all three ash samples was reported as a ‘very strong reaction’ and Locations 1 and 2 were rated 5 where ANC is >400 kg H_2SO_4/t. The elevated pH, fizz, and ANC values are indicative of fresh or minimally leached ash. Leached ash typically has lower concentrations of alkalinity and lower pH and associated negligible fizz and ANC values.

NAG directly evaluates the generation of sulfuric acid within a sample. The NAG procedure includes a final titration to pH 4.5 and finally pH 7. The reported titration value at pH 4.5 includes acidity due to free acid (sulfuric acid, H_2SO_4) in addition to soluble iron and aluminium. The titration value at pH 7 also includes metallic ions that precipitate as hydroxides between pH 4.5 and 7. The results of the NAG tests also support the low probability of acid production potential with the ash samples.

NAPP represents the theoretical balance of a samples capacity to generate acid (MPA) and its capacity to neutralise (ANC). If the MPA is less than ANC, then the NAPP is negative and the sample may have sufficient ANC to prevent acid generation; however, if the MPA exceeds the ANC then the NAPP is positive and the same may be acid generating. All three ash samples report negative NAPP values.

The acid-producing potential is plotted as **Figure 6-4**, which shows Locations 1, 2, and 3 as non-acid forming.

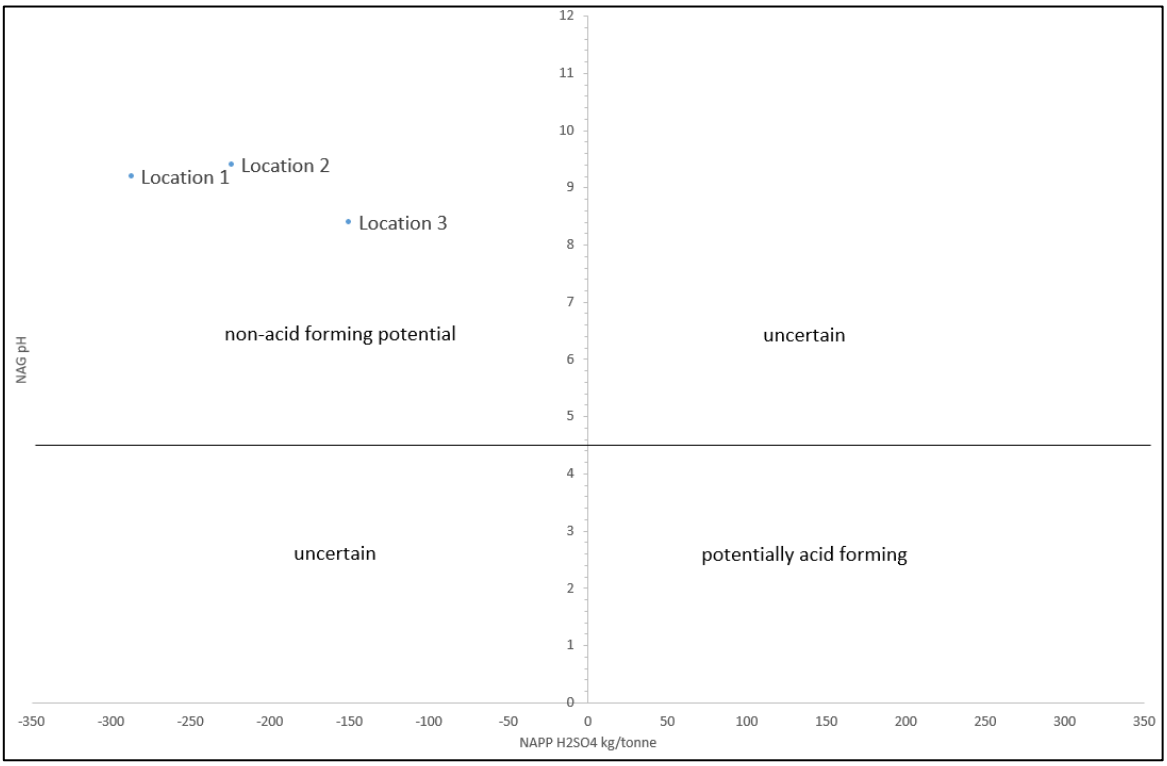

Figure 6-4 Ash Pond 1 Solid Samples – Acid Forming Potential Plot

In summary, the fresh ash material represents an elevated capacity for acid neutralisation.

6.2.2.3 Ash Solids – Major Ions

The major ion concentrations are provided in **Figure 6-5** and **Table 2** (attached).

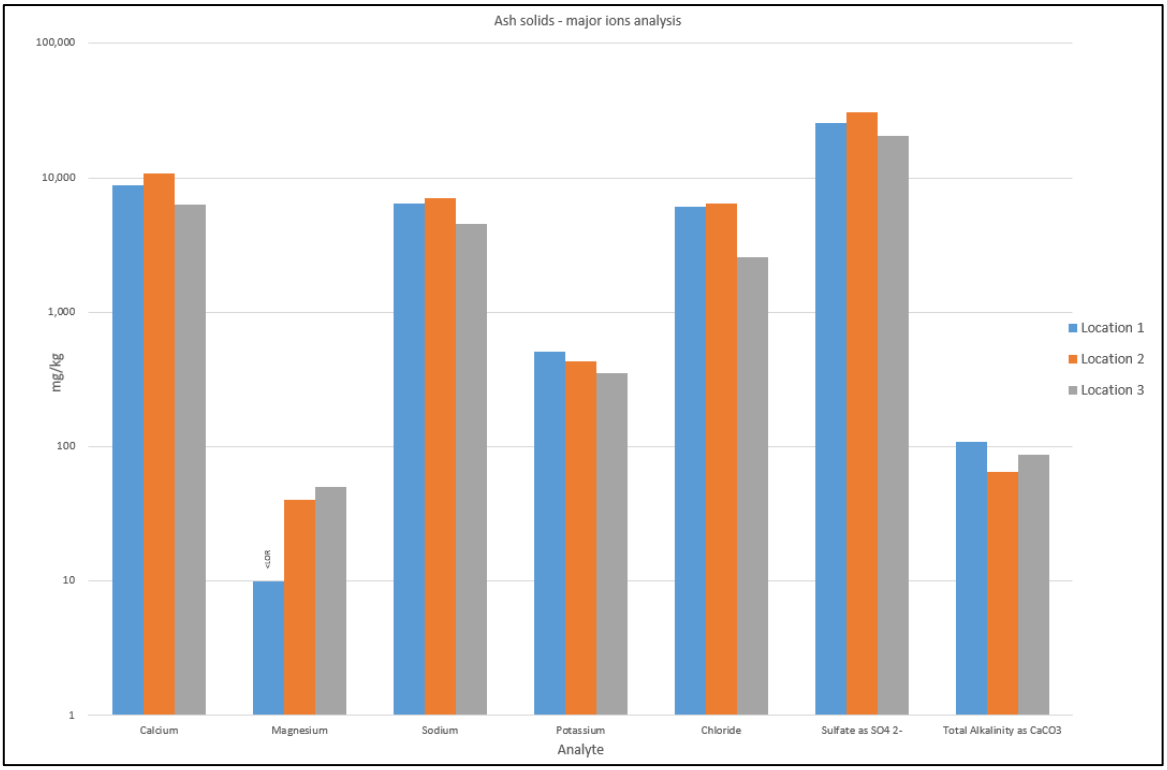

Figure 6-5 Ash Pond 1 Solids – Major Ions Analytes 2016

The analytical results for major ion concentrations in ash solids (**Figure 6-6** and **Table 2**[attached]) fall within similar ranges of concentrations presented in previously published references (Beattie, 2003).

6.2.2.4 Ash Solids – Minor Ions

Cadmium, molybdenum, tin, and selenium all reported concentrations below the laboratory limit of reporting (LOR), refer to **Figure 6-6**.

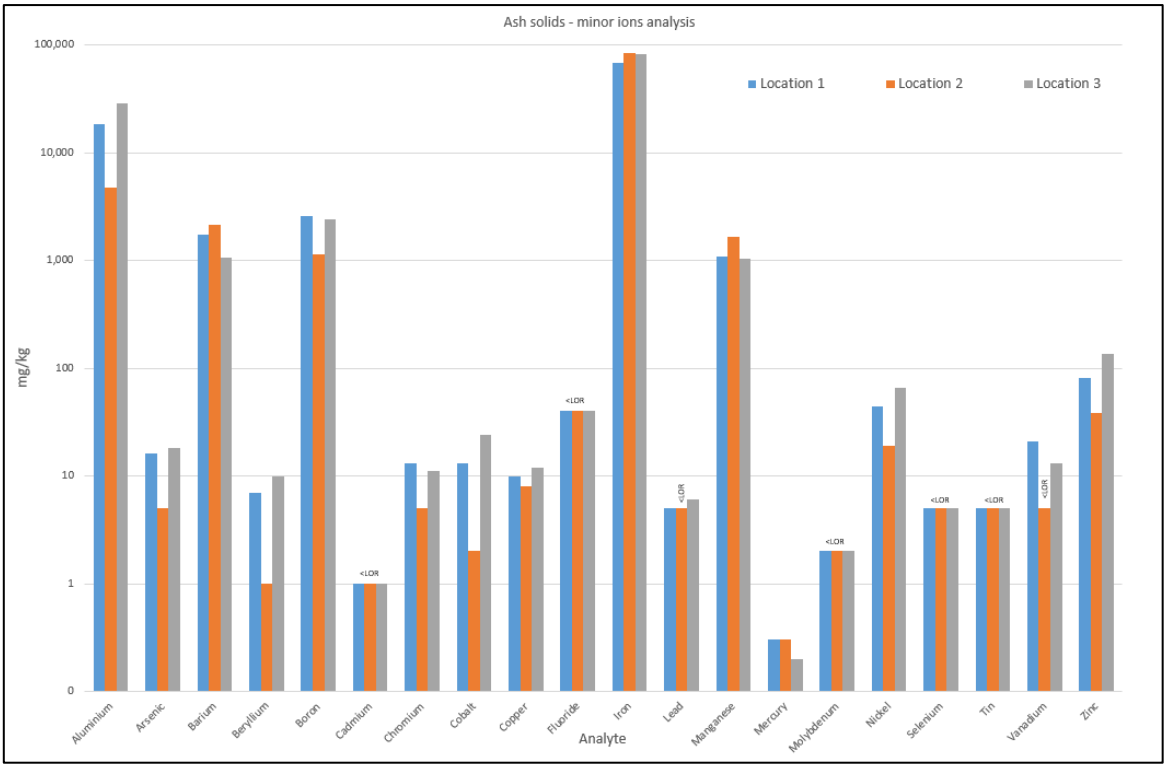

Figure 6-6 Ash Pond 1 Solids – Minor Ions 2016

The analytical results for minor ion concentrations in ash solids (**Figure 6-6**) fall within similar ranges of detectable concentrations presented in previously published references (Beattie, 2003); refer to **Figure 6-1** and GHD (2012).

6.2.2.5 Ash Pond 1 Water – Major Ions

The Ash Pond 1 water samples have been characterised for water types and major ion distribution relationships using the Geochemists Workbench (GWB) Community program. GWB can be used to check the internal consistency and carbonate equilibria of data sets and plot a variety of graphs including Piper plots.

It is noted that within some analytical reporting for total and dissolved analytes, occasionally the dissolved concentration is higher than the total concentration. These results have been reviewed by quality control procedures and the differences reported are within the experimental variation of the analytical methods.

Three samples of ash pond water were collected from Ash Pond 1. A range of analyses were carried out on the Ash Pond 1 samples (**Table 8**, attached) which included:

1. Major ions; and
2. Total and dissolved minor anions.

The Ash Pond 1 water plots as a sodium sulfate water type (**Figure 6-7**). All the ash pond samples are supersaturated with calcium carbonate which is a function of the pH (average pH 8.25).

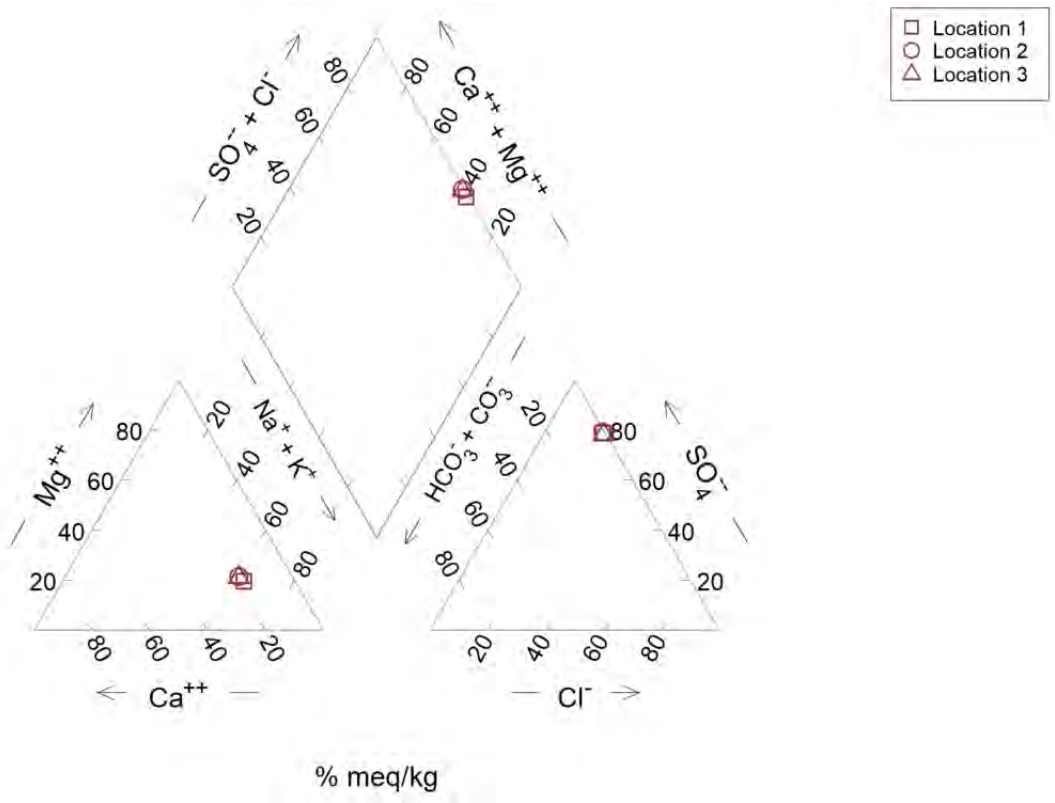

Figure 6-7 Piper Plot Ash Pond 1 Surface Water Locations

Major ion distribution is also provided in **Figure 6-8**.

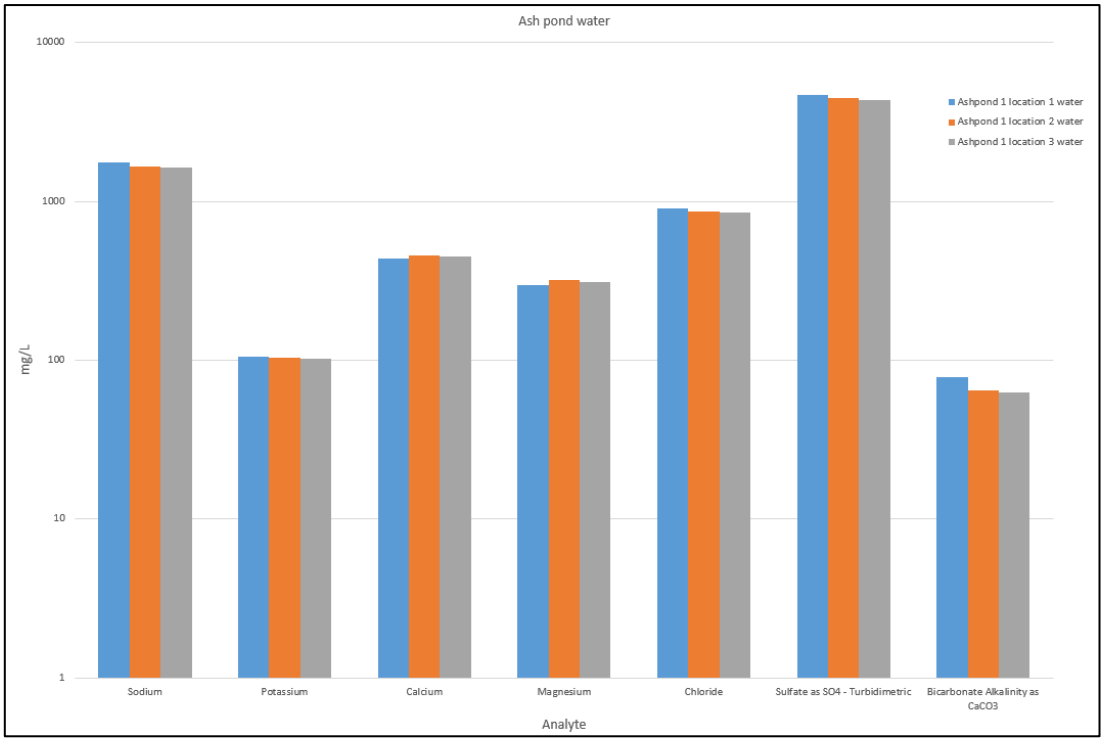

Figure 6-8 Ash Pond 1 Water – Major Ions 2016

In comparison to the historical major ion concentrations, there appears to be a good correlation between the data presented in **Figure 6-2** and **Figure 6-8**.

6.2.2.6 Ash Pond Water - Minor Ions

The Ash Pond 1 water is characterised by low to non-detectable concentrations of minor ions. Total and dissolved arsenic, beryllium, cadmium, chromium, copper, iron, lead, mercury, selenium, tin, and vanadium are all reported at or below the laboratory LOR. Minor ion distribution is dominated by boron (greater than 10 mg/L), followed by aluminium, barium, and manganese (**Figure 6-9** and **Table 8** [attached]).

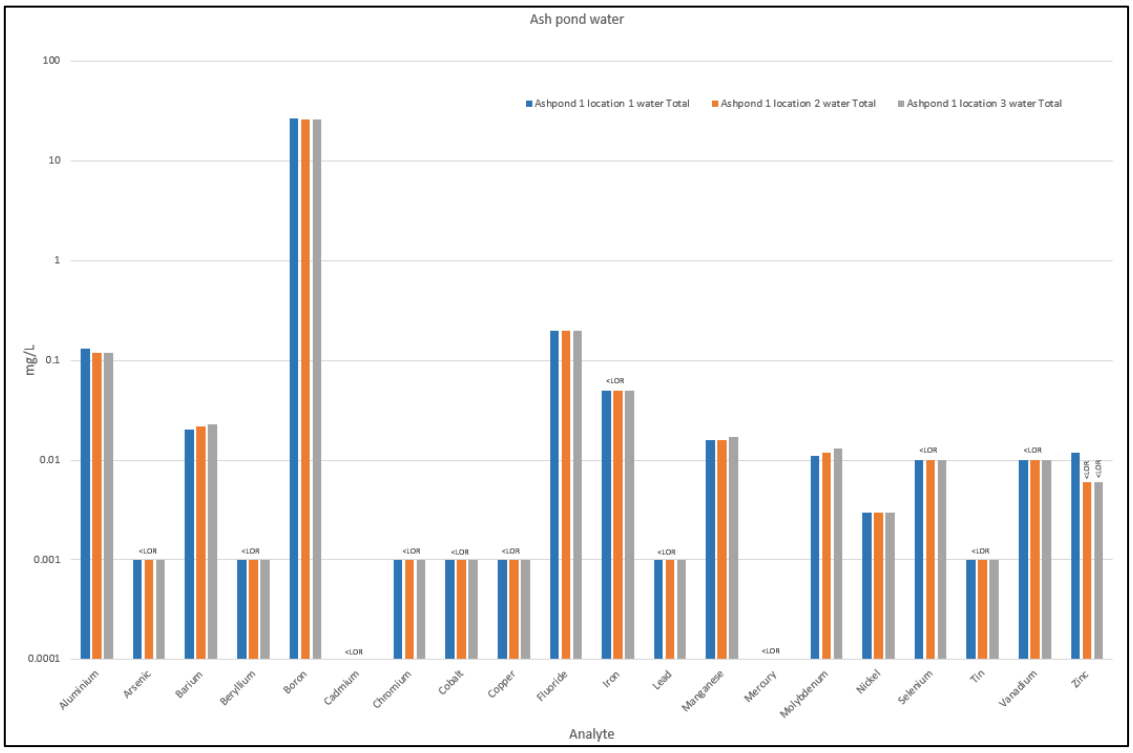

Figure 6-9 Ash Pond 1 Water – Minor Ion Concentrations 2016

6.2.3 Leachable Fraction Analysis

A sample of ash solid material was leached using Ash Pond 1 surface water as the reagent water. The ASLP method was used for the leachate procedure but instead of using a laboratory-derived reagent water (pH 5), a site representative reagent water was used, Ash Pond 1 water. The ash pond water has been in contact with the ash solid material for an extended period (years to decades). The comparison between Ash Pond 1 water and the leachable analyses provides an indication of the equilibrium between the Ash Pond 1 water and solid material and future porewater characteristics within the consolidated leached ash area.

Leachable fraction and Ash Pond 1 water analyses are provided in **Figure 6-10**.

The results of the ash solid, ash pond water and leachable fraction analyses are provided in **Table 7** to **Table 9** (attached).

The ASLP results for the Ash Pond 1 water and ash solids indicate that the main variances between the analyses are related to alkalinity and pH. The pH is observed to increase from pH 8.22 (Ash Pond 1 water) to pH 9.8 (leachate). Accompanying the increase in pH are increases in carbonate and hydroxide alkalinity and a decrease in bicarbonate alkalinity. The changes in relative abundance of alkalinity species is as expected with the change in pH. It is likely that the increase in pH initially

occurred when water came into contact with the ash material within the ponds. Over time, the hydroxide species would have been scavenged by metal cations to form insoluble precipitates, which in turn would have decreased the pH. As observed in **Figure 6-10** and **Figure 6-11**, most of the analytes report negligible changes between ash pond water and the leachable fraction of ash solids in contact with ash pond water. This supports a hypothesis that the water is anticipated to be in equilibrium with the ash solids within Ash Pond 1.

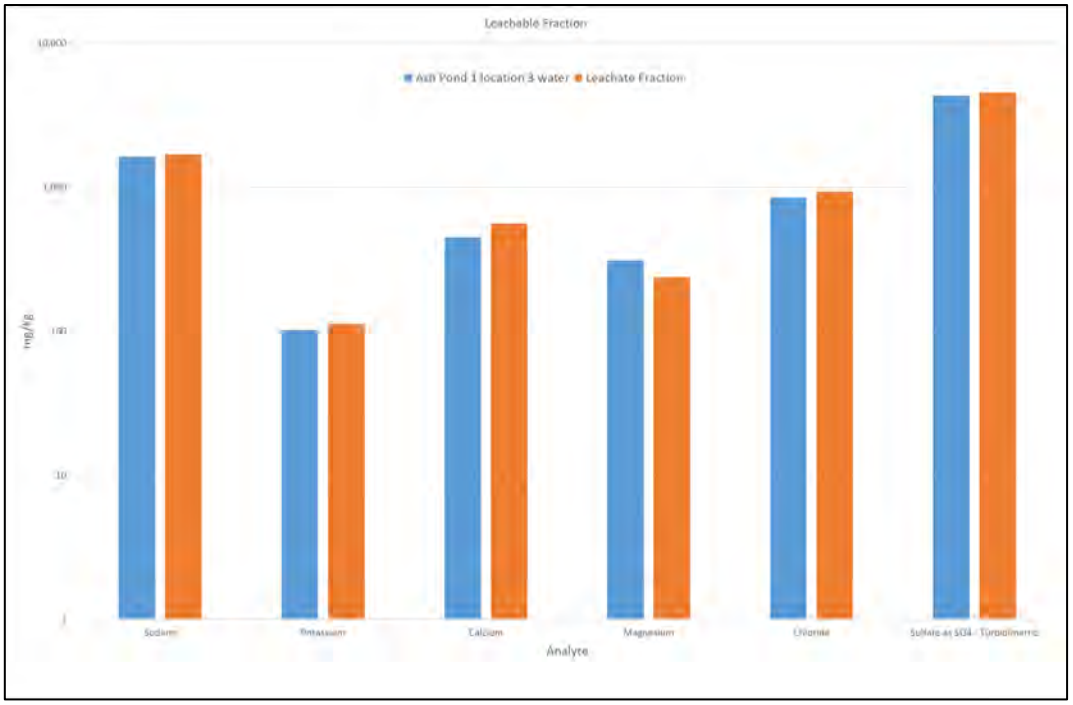

Figure 6-10 Major Ions – Ash Pond 1 Water and Leachable Fraction Analyses 2016

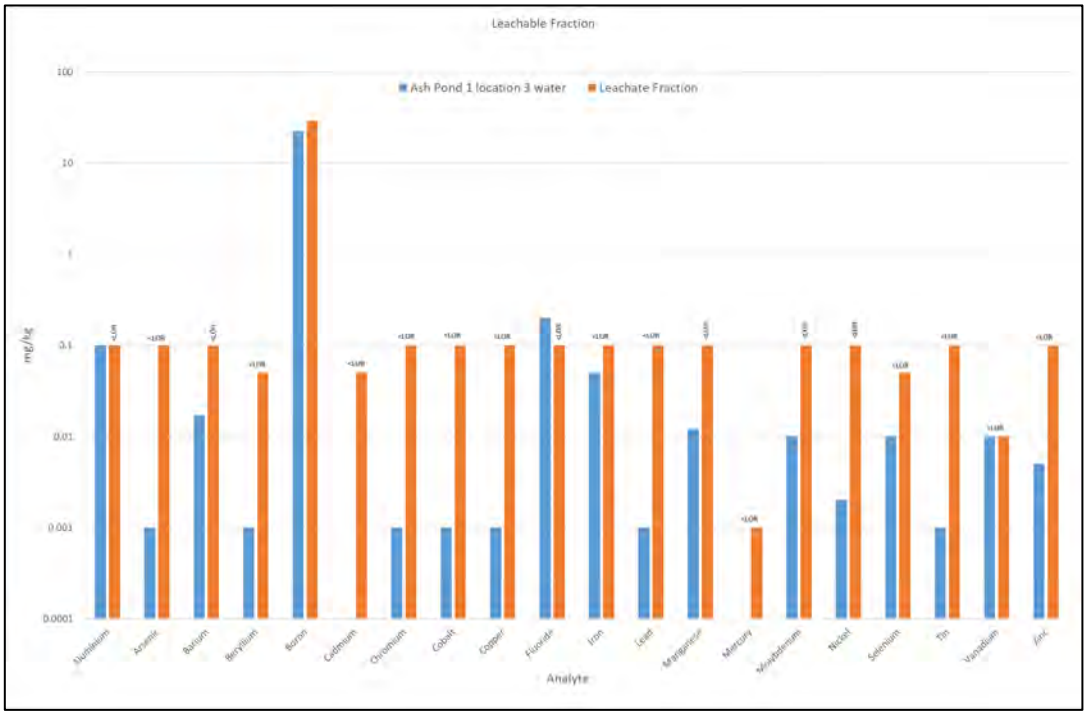

Figure 6-11 Minor Ions – Ash Pond 1 Water and Leachable Fraction Analyses 2016

Note the differing LORs between the Ash Pond 1 water and leachable fraction analysis. The LOR achieved for the leachable fraction analysis is observed to be between one and three orders of magnitude higher than that for the Ash Pond 1 water.

In summary, ASLP testing conducted using Ash Pond 1 solids and water reported limited leaching potential for metals from the ash materials. The results of these tests indicated that the majority of metals were strongly bound to the ash matrix. Boron, ammonia, and nitrate/nitrite were the only constituents detected in the leachable fraction.

6.3 Consolidated Leached Ash Characterisation – 2021

During September 2021 a two-day field sampling event collected samples for permeability, chemical, and ASLP analysis. The sampling event was focussed within the clay-rich cover (over the consolidated leached ash), the consolidated leached ash and the underlying fill material. The objective was to gather permeability data and understand the chemical profiles of the CLA, clay-rich cover, and underlying fill material. Only the CLA results are presented and discussed within this section. Refer to **Section 7** for the discussion of clay-rich cover and fill material characterisation.

The site location plan is provided as **Figure 1** (attached) and sample locations within **Figure 6** (attached).

Bore logs are provided as **Appendix G**.

6.3.1 Permeability Testing

Permeability test results are presented in **Table 6-6**. All results are less than $5x10^{-9}$ m/sec and the geomean for each material group is less than $1x10^{-9}$ m/sec. Ash permeability results are observed to be very similar to those reported for the clay-rich cover layer (refer to **Section 7.1**).

Table 6-6 Permeability Test Results (de-ionised water permeameter method)

Alcoa ID	Material	Texture	Permeability (m/sec)
ANG_21_181	Ash	Silty CLAY	$8x10^{-10}$
ANG_21_185	Ash	CLAY	$2 x10^{-10}$
ANG_21_187	Ash	Silty CLAY	$9 x10^{-9}$
ANG_21_191	Ash	CLAY	$1 x10^{-9}$
ANG_21_193	Ash	Silty CLAY	$4 x10^{-10}$
ANG_21_196	Ash	Clayey SILT	$2 x10^{-9}$
ANG_21_202	Ash	Silty CLAY	$5 x10^{-9}$

Soil testing was carried out on samples to assess the Emerson Class Number. This test indicates the degree of dispersivity, or reactivity displayed by the samples when in contact with de-ionised water and provides an indication of the ash (and surrounding material) stability under saturated conditions. The results show that most of the samples did not disperse in de-ionised water apart from two samples that showed a slight to moderate reaction.

The laboratory geotechnical results are presented in **Table 10** (attached) and **Appendix E**. Emerson results are presented in **Table 11** (attached).

A west-east cross section through the consolidated leached ash area based on selected bore logs within **Appendix G** is provided as **Figure 7** (attached).

6.3.2 Chemical Testing

Chemical testing on the leached ash samples included total and leachable fraction analysis at two pH values, pH 2.9 and pH 7. These two pH values were selected based on the pH conditions in the vicinity of the CLA area.

The CLA and leachable fraction analyses are provided in **Table 12** and **Table 13** (attached).

The laboratory analysis reports are presented in **Appendix E**.

Laboratory and field sample QA/QC is provided in **Appendix F**.

Total major and minor ion analysis results are presented in **Figure 6-12** through **Figure 6-15**.

Major ion concentrations are generally lower than those reported in 2016, particularly sodium and chloride (**Figure 6-5**).

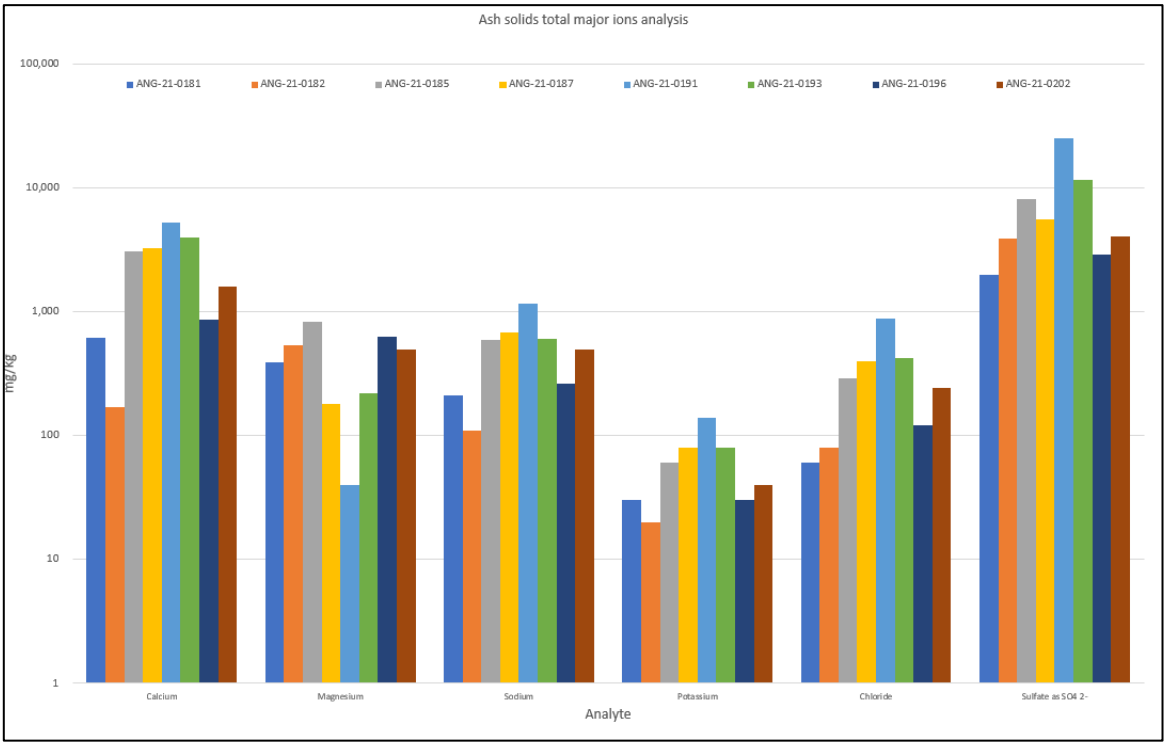

Figure 6-12 Leached Ash Solids Total Major Ions Analysis 2021

Minor ion concentrations are mostly unchanged in comparison with 2016 (**Figure 6-6**) with the exception of fluoride which is now detected above the LOR.

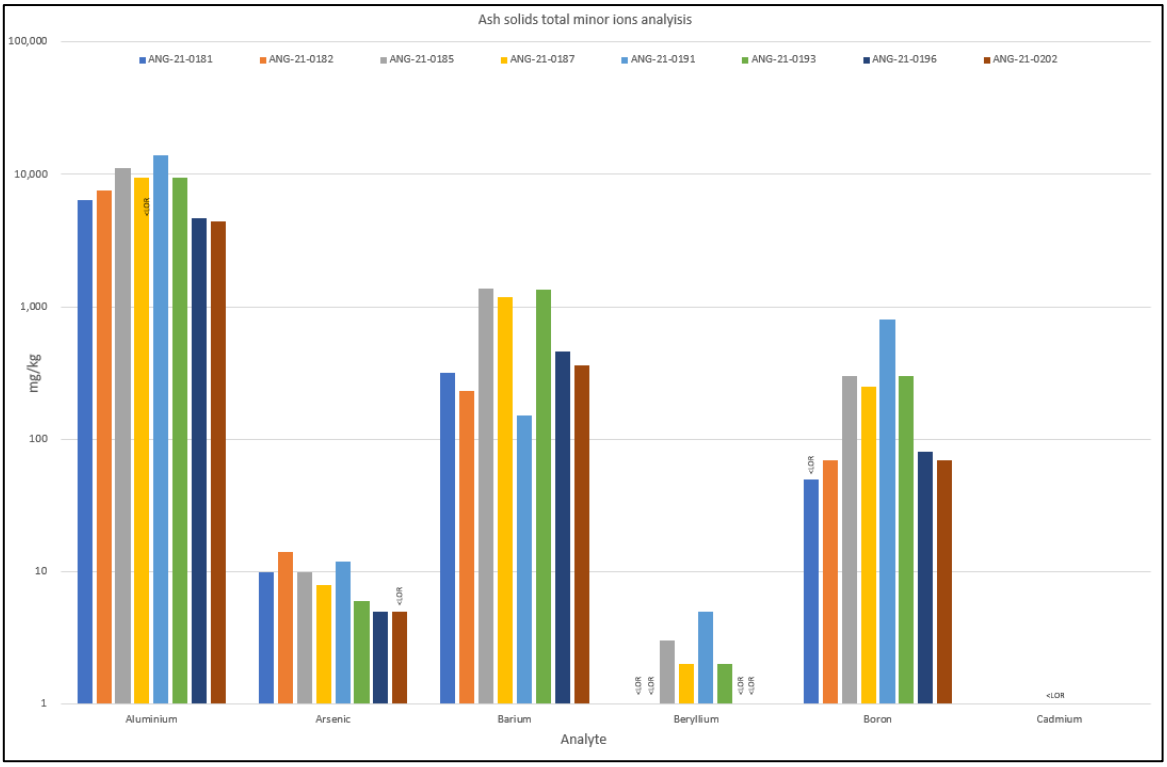

Figure 6-13 Leached Ash Solids Total Minor Ions Analysis (aluminium through cadmium) 2021

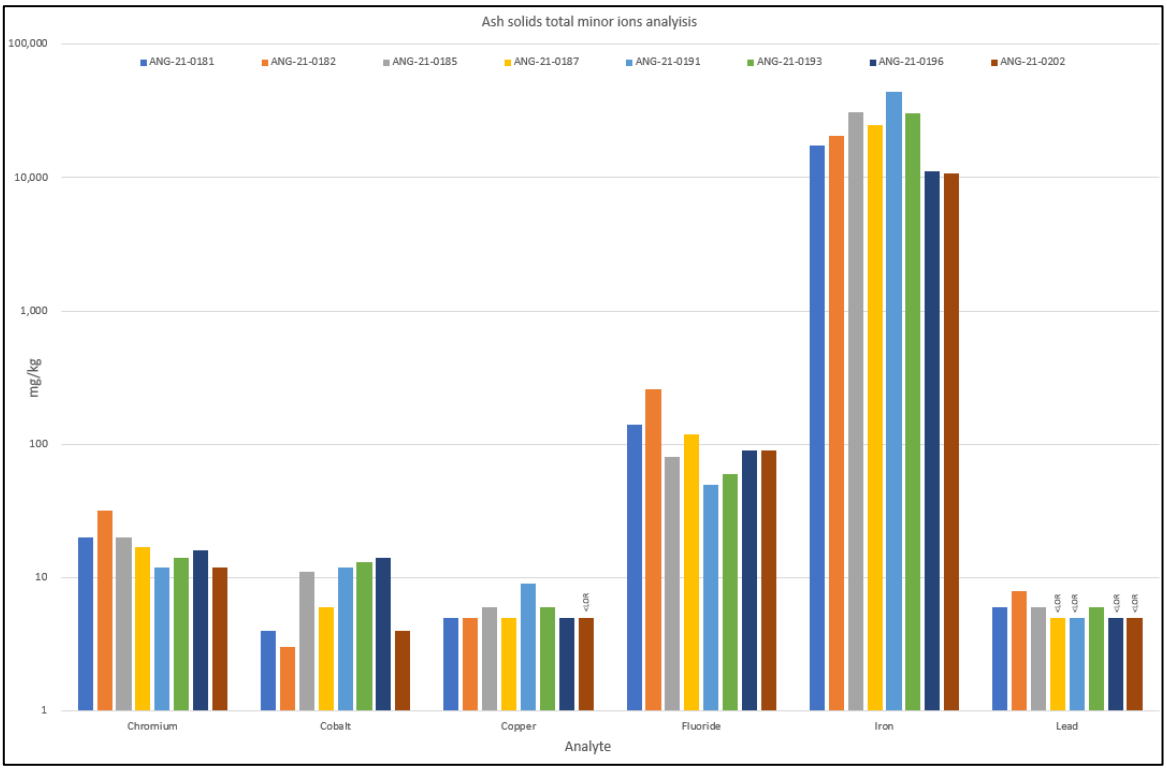

Figure 6-14 Leached Ash Solids Total Minor Ions Analysis (chromium through lead) 2021

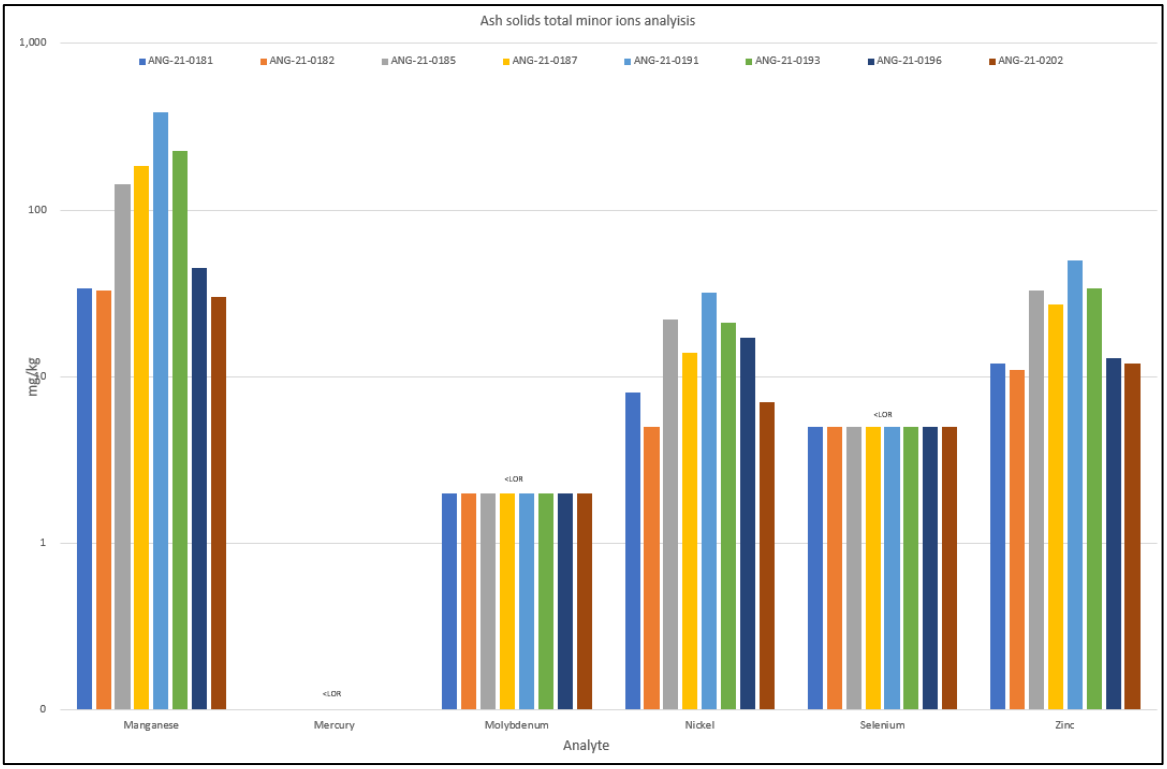

Figure 6-15 Leached Ash Solids Total Minor Ions Analysis (manganese through zinc) 2021

In comparison to the typical ranges of minor ions encountered in coal ash, Anglesea leached ash is representative of the lower end of the range presented in **Table 6-7**. The lower concentrations are most likely attributed to the extended leaching of the ash in the ash ponds.

Table 6-7 Minor Ions – Typical Ranges in fresh CCA (after Eary et al, 1990)

Analyte	Fly Ash (mg/kg)	Bottom Ash (mg/kg)	Anglesea Fly Ash (mg/kg) Beattie (2003)
Arsenic	2 – 440	0.02 – 168	7.5
Barium	1 – 13,800	11 – 9,360	2,974
Boron	10 – 5,000	2 – 513	4,148
Cadmium	0.1 – 130	0.1 – 4.7	3.6
Chromium	4 – 900	0.2 – 5,820	29
Copper	33 – 2,200	4 – 930	11
Lead	3 – 2,100	0.4 – 1,100	14
Manganese	25 – 3,000	60 – 1,900	991
Mercury	0.01 – 12	0.01 – 4	0.3
Molybdenum	1 – 140	1 – 440	1.2
Nickel	2 – 4,300	<10 – 2,900	67
Selenium	0.2 – 130	0.1 – 10	7.4
Zinc	14 – 3,500	4 – 1,800	105

ASLP testing was conducted on ash samples at two different pHs, pH 2.9 and pH 7. The leachable fraction concentrations are provided in **Figure 6-16** to **Figure 6-19**.

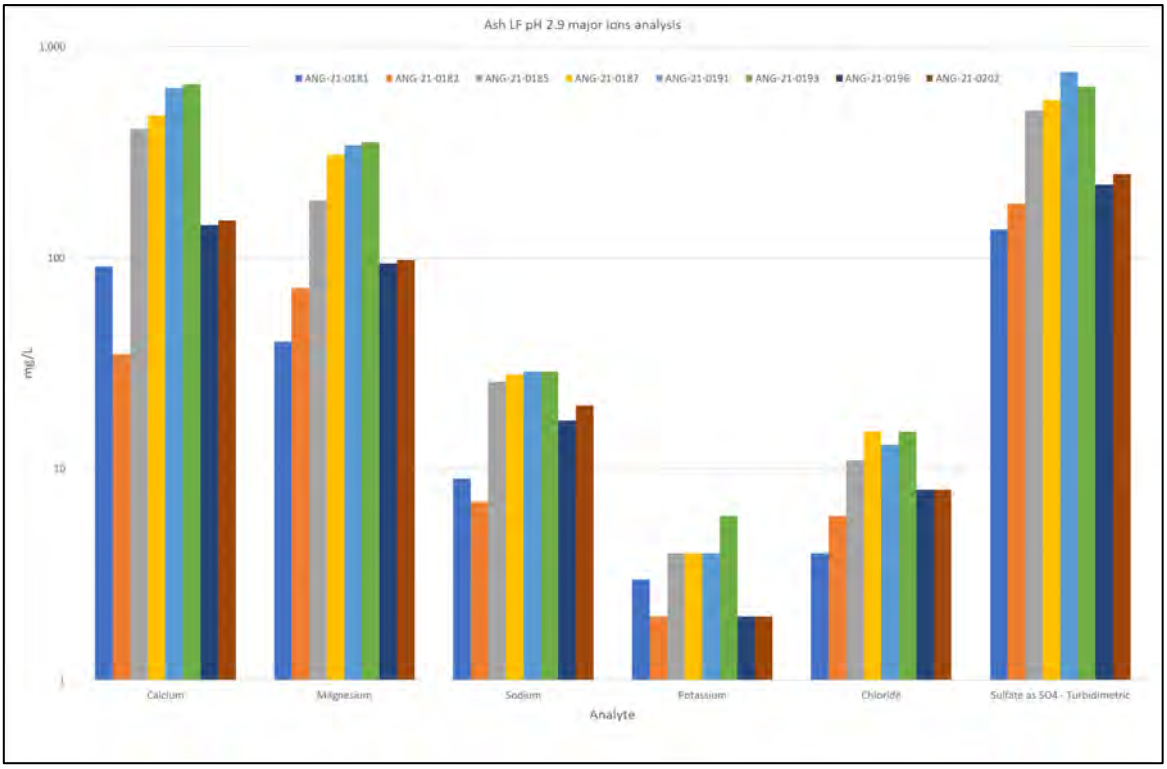

Figure 6-16 Leached Ash Leachable Fraction pH 2.9 Results – Major Ions 2021

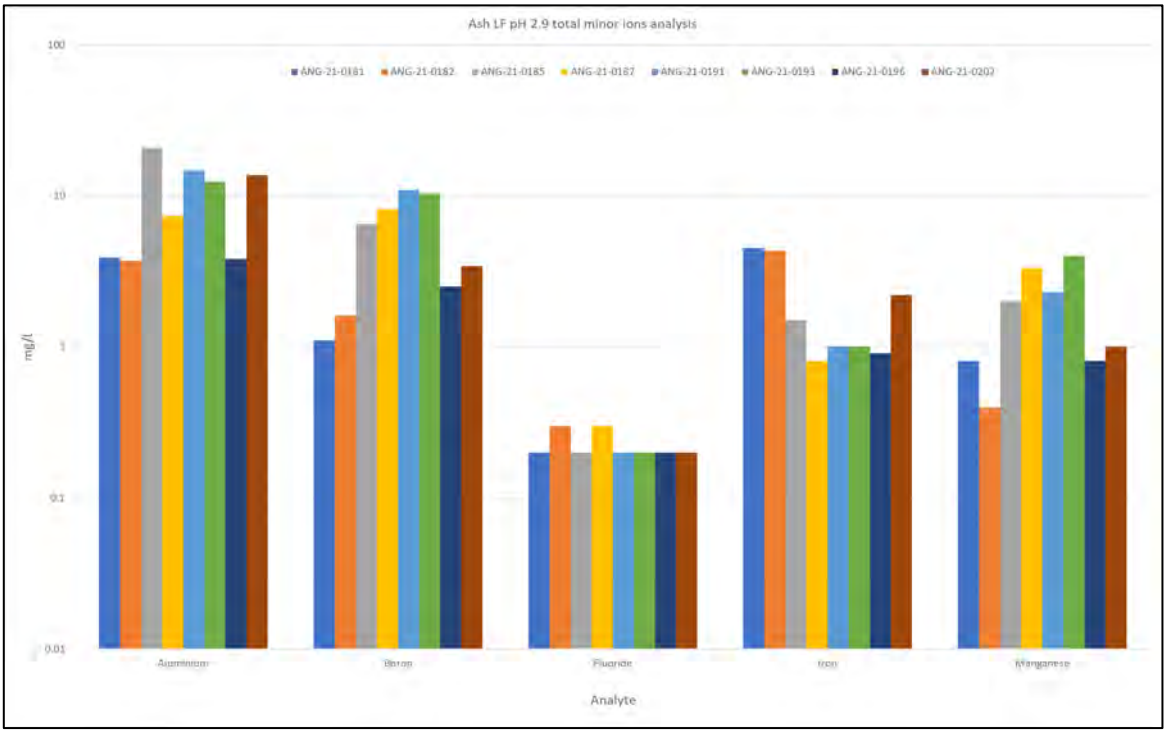

Figure 6-17 Leached Ash Leachable Fraction pH 2.9 Results – Minor Ions[28] 2021

[28] The following minor ions were reported below the LOR and not plotted – arsenic, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, molybdenum, selenium, zinc. Barium and nickel where also omitted from the plot as they both reported concentrations at or below the LOR of 0.1 mg/L.

The comparison of leachable fraction concentrations at pH 2.9 and pH 7 does not reveal any marked differences with the exception of manganese which appears to be less leachable at neutral pH.

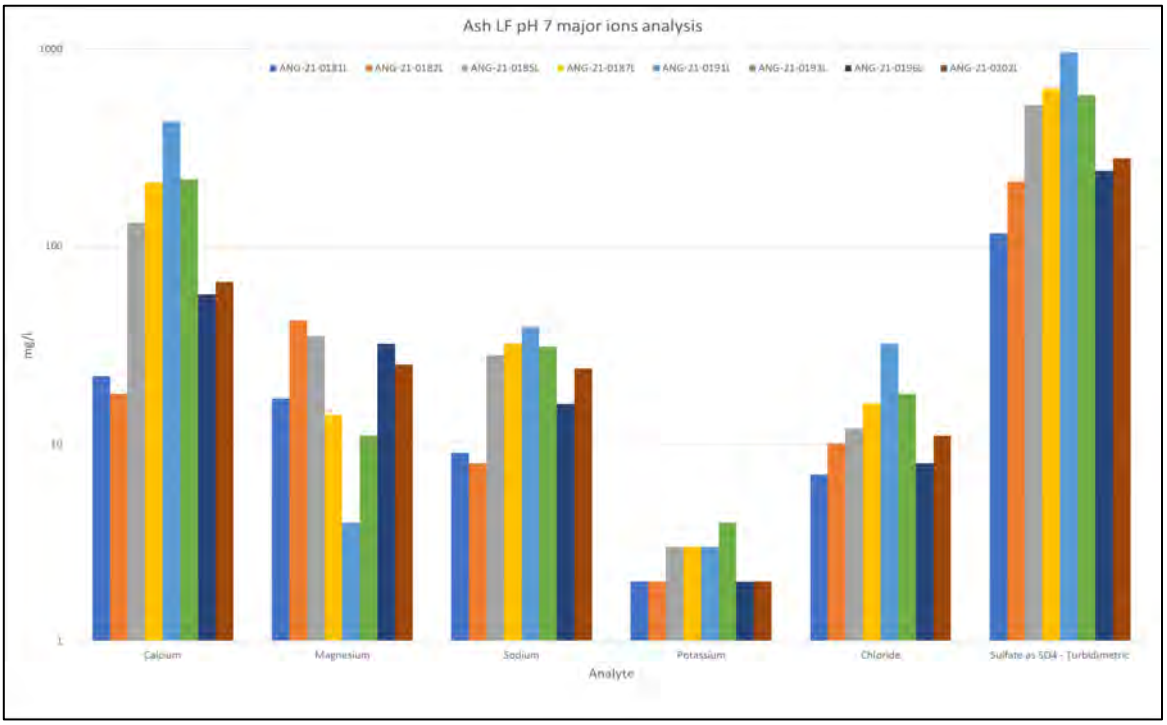

Figure 6-18 Leached Ash Leachable Fraction pH 7 Results – Major Ions 2021

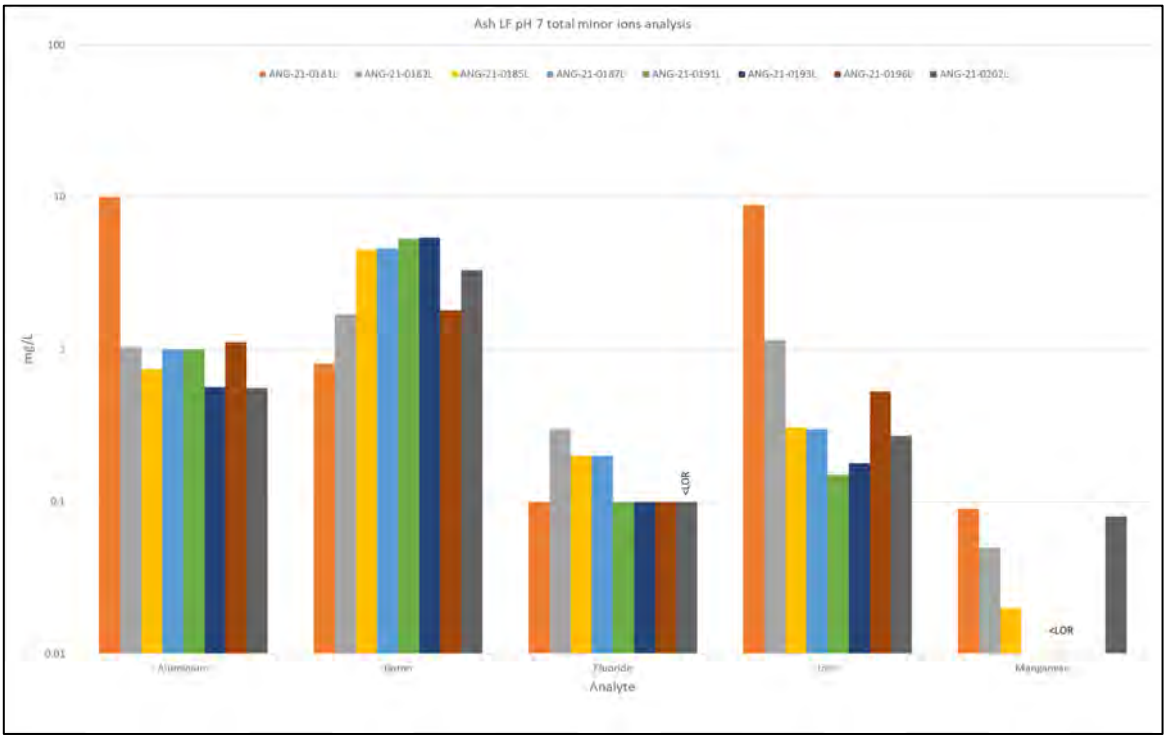

Figure 6-19 Leached Ash Leachable Fraction pH 7 Results – Minor Ions[29] 2021

[29] The following minor ions were not plotted – antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iodide, lead, mercury, molybdenum, nickel, phosphorus, selenium, silver, thallium, tin, vanadium, zinc as they reported concentrations at or below the analyte LOR.

6.3.3 Comparison of Leached Ash Leachable Fraction with Water Body and Groundwater Quality

Due to the low permeability of the clay-rich fill material surrounding the CLA and the retardation properties of the clay, it is highly unlikely that constituents in leached ash pore water will impact either groundwater or surface water in the vicinity. This is also supported by the outcomes of the numerical modelling (**Section 9**).

A comparison of the acidic leachable fraction analysis of ash sample ANG-21-191 with the current groundwater (groundwater monitoring location, DBG MB6) and surface water quality (water body) in the vicinity of the consolidated leached ash indicates that if a direct discharge of ash pore water occurred into the water body it is unlikely to be detectable (**Table 6-8**).

Only iron and calcium are elevated in the leached ash leachable fraction in comparison to the water body. A direct discharge of leached ash pore water to the water body would not be subject to any retardation or dilution mechanisms that could occur along the discharge pathway. Aluminium, boron, and calcium are elevated in the leached ash leachable fraction in comparison to shallow groundwater in the vicinity of DBG MB6; again, this would assume an unattenuated discharge of leached ash pore water to the location of DBG MB6.

Table 6-8 Comparison of Leached Ash Leachable Fraction, Groundwater, and Water Body Water Quality

Sample ID	ANG-21-191	ANG-22-104	ANG-22-105
Sample Location	ADBH04	DBG MB6	Water Body
Media	Consolidated Leached Ash ASLP pH 2.9 Leachable Fraction	Groundwater	Surface Water
Sample Date	14/09/2021	27/07/2022	27/07/2022
Aluminium (mg/L)	3.9	0.12	4.69
Boron (mg/L)	1.1	0.313	1.16
Calcium (mg/L)	91	30	85
Chloride (mg/L)	4	666	471

7 Consolidated Leached Ash Area Characterisation – 2022

As recommended by BlueSphere as part of the Independent Peer Review process, a four-day field sampling event was held in June and July 2022 to collect additional samples for further permeability, chemical and ASLP analysis. The 2022 sampling event was undertaken to compliment the 2021 sampling event on the advice of BlueSphere. The spatial coverage and number of investigation locations for the 2022 event was discussed in detail as part of the Independent Peer Review process so that the combination of the 2021 and 2022 sampling events meet the requirements of the AS4482.1 Sampling Design Guidelines. Australian Standard, AS4482.1-2005, was used as a guide to ensure a sufficient sample density was achieved to characterise the clay-rich cover and fill material, in consultation with BlueSphere. A sufficient number of CLA samples had been collected in 2021 for characterisation. The clay-rich cover and fill material samples collected in 2021 are also presented and discussed in this section.

The sampling event was focussed within the clay-rich cover (over the CLA) and fill material areas surrounding the CLA. The objective was to gather more permeability data to support the assumptions made in the hydraulic modelling assessment and to assess the potential for infiltration impacts of residual ash pond water (from sluiced ash) discharged from the CLA area to the water body in 2016.

The site location plan is provided as **Figure 1** (attached) and sample locations within **Figure 6** (attached). Bore logs are provided as **Appendix G**.

7.1 Permeability Testing

Permeability test results from 2021 and 2022 are presented in **Table 7-1**.**Table** 7-2 and **Table 7-3**. All results were reported at less than 7 $x10^{-8}$ m/sec and the geomean for each material group is less than $2x10^{-9}$ m/sec with the exception of the 2021 fill material group. This result is skewed by a sample of organic clay with a permeability of $6x10^{-8}$ m/sec which is not representative of the other fill material sample permeabilities. This sample is considered to be an outlier in the dataset, however has been retained. Samples tested with both de-ionised and saline water reported minimally different permeabilities.

Table 7-1 Permeability Test Results 2021 (de-ionised water permeameter method)

Alcoa ID	Material	Texture	Permeability (m/sec)	Geomean (m/sec)
ANG-21-184	Clay rich layer	Sandy CLAY	$2x10^{-10}$	$4.7x10^{-10}$

The laboratory geotechnical results are presented in **Table 10** and **Table 14** (attached) and **Appendix E**.

7.2 Chemical Testing

7.2.1 Initial Analysis

Two locations (ADBH32 and ADBH33) were advanced within the area where the discharge of leached ash pond water occurred. Three samples were collected at each location within elevations 0-2 mbgl, 2-4 mbgl, and 4-6 mbgl. Total and ASLP analysis was conducted on each sample. The leaching procedure was carried out at two pH values, pH 2.9 and a pH representative of de-ionised water (pH 5 to 6). The results have been tabulated and not plotted due to the low concentrations and non-detects reported for this group of samples.

The laboratory analysis reports are presented in **Appendix E**.

Laboratory and field sample QA/QC is provided in **Appendix F**.

The laboratory results are provided within **Table 15** and **Table 16** (attached).

Table 7-4 and **Table 7-5** provide the summary results of the total major and selected minor ion analysis from the discharge area. The total major and selected minor ion analysis from a sample of the clay-rich cover (from 2021 field sampling event) has also been added for comparison. A very similar profile of major and minor ion concentrations is observed for both the fill material in the discharge area and the clay-rich cover.

Table 7-6 and **Table 7-7**, **Table 7-8** and **Table 7-9** present the summary results of the ASLP analysis at pH 2.9 and a pH representative of de-ionised water (pH 5 to 6), respectively; again, a very similar profile of major and minor ion leachable fraction concentrations is reported for both the fill material in the discharge area and the clay-rich cover. The minor ions selected are representative of a small group of consistently detectable analytes including aluminium, which can be indicative of coal, ash, and ash pond water. Boron, which is also a coal/ash indicator analyte, was not reported above the LOR in totals or leachable fraction results. ASLP analysis of ash solids and ash pond water quality typically reports the presence of boron at concentrations greater than 10 mg/L.

Based on the results of the totals and ASLP analyses, impacts from the leached ash water discharge (and potential infiltration) appear to be limited in concentration and do not change the overall outcomes of the risk assessment; however, additional samples which were kept on hold were submitted for total and leachable fraction analysis the results of which are discussed in **Section 7.2.2**.

7.2.2 Additional Analysis

Additional samples (number = six) were selected for analysis from four locations (ADBH13, ADBH17, ADBH20A, and ADBH31). These locations were advanced in the Haul Road (ADBH13, ADBH17, and BH20A) and Berm (ADBH31) domain areas (**Figure 6**, attached). Samples were recovered from 0-2 m bgl (ANG-22-0026, 2-4 m bgl ANG-22-0031, and ANG-22-0050) and 4-6 m bgl (ANG-22-0028, ANG-22-0103, and ANG-22-0052). Total and ASLP analysis was conducted on each sample. The leaching procedure was carried out at two pH values, pH 2.9 and a pH representative of de-ionised water (pH 5 to 6). The results have been tabulated and not plotted due to the low concentrations and non-detects reported for this group of samples.

All samples were collected from the clay-rich fill material and characterised as clayey sand or sandy clay. The exception was sample ANG-22-0103, although it was collected within the Haul Road domain it consists of coal gravel (approximately 1.4 m in thickness). This sample was analysed to gain an understanding of the range and magnitude of constituents in the remnant coal and the chemical influence of the fill material.

The laboratory analysis reports are presented in **Appendix E**.

Laboratory and field sample QA/QC is provided in **Appendix F**.

The laboratory results are provided within **Table 17** and **Table 18** (attached).

Table 7-11 and **Table 7-12** provide the summary results of the total major and selected minor ion analysis from the discharge area. The total major and selected minor ion analysis from a sample of the clay-rich cover (from 2021 field sampling event) has also been added for comparison. A very similar profile of major and minor ion concentrations is observed for both the fill material in the discharge area and the clay-rich cover.

Table 7-13 and **Table 7-14**, **Table 7-15** and **Table 7-16** present the summary results of the ASLP analysis at pH 2.9 and a pH representative of de-ionised water (pH 5 to 6) respectively; again, a very similar profile of major and minor ion leachable fraction concentrations is reported for both the fill material in the Haul Road and Berm domain areas. The minor ions selected are representative of a small group of consistently detectable analytes including aluminium, which can be indicative of coal, ash, and ash pond water. Boron, which is also a coal/ash indicator analyte was reported above the LOR for leachable fraction results in ANG-22-0026, ANG-22-0052 and ANG-22-0103 (de-ionised water leach). The results ranged from 0.4 to 1.2 mg/L. ASLP analysis of ash solids and ash pond water quality typically reports the presence of boron at concentrations greater than 10 mg/L. Sample ANG-22-0103 (coal gravel) reported elevated sulfate (13,000 mg/kg) in comparison to all other samples. This is more elevated than historical chemical quality of coal exposed in the western face of the former coal mine (draft MRCP, 2017). The difference is likely related to the limited exposure and leaching of the coal gravel encountered beneath the Haul Road.

Table 7-10 Coal Chemical Characteristics (draft MRCP, 2017)

Analyte	Units	Min	Max	Mean	Median	90th Percentile
Calcium	mg/kg	20	160	42	40	118
Magnesium	mg/kg	20	290	44	30	120
Sodium	mg/kg	10	260	76	80	195
Potassium	mg/kg	<10	<10	<10	<10	<10
Chloride	mg/kg	30	90	46	50	69
Sulfate as SO_4^{2-}	mg/kg	160	2,880	521	465	1,911
Aluminium	mg/kg	3,320	15,800	5,085	4,150	7,383
Barium	mg/kg	20	150	55	58	118
Boron	mg/kg	20	30	23	23	27
Chromium	mg/kg	2	80	5	4	10
Fluoride	mg/kg	50	240	95	100	224
Iron	mg/kg	3,650	621,000	8,475	6,185	8,952
Lead	mg/kg	1	11	2	2	8
Manganese	mg/kg	3	17	8	9	15
Nickel	mg/kg	4	20	8	7	18

Table Notes:
mg/kg = milligrams per kilogram

Based on the results of the totals and ASLP analyses, impacts from the leached ash water discharge (and potential infiltration) appear to be limited in concentration, however do not change the overall outcomes of the risk assessment.

7.3 Summary

The range of major and minor ions which are found in the leached ash are overall representative of the low end of concentrations generally reported in fly and bottom ash derived from brown coal. The management of ash at the Anglesea site has involved the storage and leaching in ash ponds at the power station and over time the leached ash has been dried and trucked or more recently dredged (2016) to the former mine pit. To support the risk assessment associated with the presence of the CLA area, ash characterisation studies have been completed over the last six years; this information, in addition to the characterisation of the materials surrounding the CLA, has been used to support the assessment that there are only low risks associated with the CLA being inundated and submerged by the developing water body over time.

The leached ash leachable fraction data from 2016 and 2021 indicates that major ions (calcium, magnesium, sodium, chloride, sulfate, and a lesser extent potassium) and only minor ions (aluminium, boron, fluoride, iron, and manganese) are leachable from the CLA.

Of these constituents, boron is considered to have the potential to be the most mobile in groundwater when the CLA and fill material become saturated over time. Permeability results collected in 2021 and 2022 using both de-ionised water and saline permeants indicate that clay-rich cover (over the CLA) and fill material in the vicinity of the CLA have average (geomean) permeabilities less than $1x10^{-9}$ m/sec. v permeabilities (de-ionised water permeant) are less than $2x10^{-9}$ m/sec.

In summary, although the magnitude of leachable ion concentrations from leached ash solids has diminished over time, there is still a potential for major and minor ions to be leached from the CLA into pore water. The data collected from the CLA and characterisation of the surrounding materials has provided a good understanding of the CLA domain and supported the development of a numerical model. To explore the risk of pore water migrating from the CLA area into the surrounding fill material, a hydraulic modelling assessment was conducted using the Geostudio package SEEP/W which adopted the permeability characteristics of the CLA, clay-rich cover, and surrounding fill material. The model has been used to simulate the recovery of groundwater within the fill material and CLA over time. Particle tracking was also used to look at the behaviour of a conservative constituent (such as boron) derived from CLA pore water. The results of this assessment are provided in **Section 9** and **Appendix H**.

8 Literature Review of Ash Management

The long-term management of CCA residues (fly and bottom ash) varies across the world, however storage of CCA is usually in ash ponds where the residence time can be months to years. After storage in ash ponds, the chemical characteristics of CCA change and leached ash is more appropriate terminology.

National and international examples of CCA management are discussed and summarised below with an emphasis on chemical characterisation and geochemical changes as CCA leaches and ages during the management process at Latrobe Valley, Victoria, Australia. A national focus on Latrobe Valley has been based on the use of brown coal as the source of CCA and a similar range of characteristics with the source and management of Anglesea CCA. This is because the properties of CCA and leachate are highly variable and depend on factors such as the provenance of the coal, efficiency of the combustion method, and the disposal or leaching method.

The aim of this literature review is to provide a comparison of management practices both nationally and internationally and to review the environmental impacts that may have been documented from leached ash deposits to the extent this can compare to and be used to inform the current CLA management strategy at Anglesea.

8.1 National Examples

Coal fired power production from Victoria's Latrobe Valley has occurred from 1924 when the first brick-built power station opened adjacent to the Yallourn open cut mine. Over the years three more power stations were built at Morwell, Hazelwood, and Loy Lang (plants A and B). In the 1990's approximately 550,000 tonnes of CCA was produced by power stations in the Latrobe Valley (Black et al, 1992). Historical management of CCA has been slurry disposal to on-site disposal ponds (Mudd et al, 1996). The ponds are underlain by low permeability clays and the design methodology was based on overseas research and initial research by the State Electricity Commission of Victoria (SECV). The SECV research centred mainly on the engineering aspects of ash containment.

Table 8-1 provides some major compound analysis of ash from the Latrobe Valley. Ash derived from Yallourn and Hazelwood appear to be the closest in composition to the Anglesea ash (**Table 6-1**).

Table 8-1 Major Compound and Element Chemical Composition of Ash from the Latrobe Valley (MacPhee, 1993)

Major Compounds	Loy Yang	Yallourn	Hazelwood	Anglesea
	% Dry Basis			
CaO	1	12.3	28.4	18.63
SO_3	3.4	21.7	15.6	18.18
MgO	2.2	18	18.8	17.55
SiO_2	60.4	1.4	6.6	14.58
Fe_2O_3	8.5	24.5	8.7	13.3
Al_2O_3	13.3	2.1	1.8	5.13
Na_2O	2.1	11	4.5	2.65
K_2O	1.2	0.4	0.4	0.19
TiO_2	1.7	0.1	0.2	0.09
Cl	<0.1	<0.1	3.4	0.02

The data provided in **Table 6-1** and **Table 8-1** show the large range in variability between Victorian brown coal composition.

Early research work (Bone, 1980 and Bone & Schaap, 1981) concluded that the majority of soluble components were leached during the fluidised transport to the disposal ponds. These constituents comprised calcium, sodium, magnesium, potassium, chloride, and sulfate. Analytical tests on ash from the disposal ponds indicated minor concentrations of soluble compounds. In addition, the elevated alkalinity of the Latrobe Valley ash appears to limit the solubility of most trace elements and maintained a high pH leachate. Subsequent studies (Black, 1990a & 1990b) indicate that submerged ash from the disposal ponds (leached for 12 months or more) has a lower soluble mass than dry bottom or fly ash directly from the furnaces. Kacavenda & McKinley (1994) primarily investigated the geotechnical properties of leached ash from Loy Yang overburden dump. The average hydraulic conductivity was estimated to be 3.5x10-6 m/sec and they stated the difference between vertical and horizontal hydraulic conductivity was small (values not documented).

Gavin Mudd[31] (currently Associate Professor at RMIT University, Victoria) conducted a research project (Mudd, 2001) into the environmental impacts of ash disposal techniques at the Loy Yang power station complex. The aim of the research was to investigate solute transport of constituents from ash into the surrounding environment. While this research does not directly relate to the submergence of the CLA at Anglesea, it does provide an insight into ash leaching and depletion of these constituents over time.

Leachate generation occurs through water contact with ash. The water-soluble salts on the surface of the ash are mobilised initially which contribute to the high salinity leachates. The dominant major ions include sodium, calcium, sulfate, and chloride. The majority of ash leachates are alkaline due to presence of calcium and magnesium oxides (**Table 8-1**). The generation of alkalinity can also be buffered by acidity generation from the oxidation of iron within the ash. The pH and redox of the high salinity leachate will control the leaching of minor ions from the ash. Leaching and aging of ash occurs through dissolution, advection, diffusion, adsorption, and precipitation processes which compete in the mobilisation and immobilisation of major and minor ions. In summary, the initial leachate has a high concentration of major ions with minor ions slowly increasing over time. The mass of major ions leached decreases and quasi- equilibrium conditions will be achieved overall in a closed or steady-state system (such as a sealed pond). True equilibrium is often not achieved for minor ions as the process of diffusion and sorption/precipitation processes compete with each other and the ash storage conditions are often dynamic (rainfall, ash excavation, and pond water discharge).

Mudd (2001) discusses the predominance of major ions in Latrobe Valley leached ash leachates (particularly sulfate) and the limited presence of minor ions or trace elements. This observation aligns with the reported ash pond water and leachable fraction analysis reported from Anglesea. The ash deposited in the Loy Yang ash pond is leached for 12 months or longer and has a lower soluble mass than when first produced. The Loy Yang ash pond minor ion concentrations in **Table 8-2** are within the same order of magnitude to those reported in **Figure 6-13** through **Figure 6-15** above, with the exception of mercury which is not detected in Anglesea leached ash.

[31] https://www.rmit.edu.au/contact/staff-contacts/academic-staff/m/mudd-dr-gavin accessed 14th February 2022

Table 8-2 Leached Ash Quality – Loy Yang Ash Pond (mg/kg) after McKinley, 1995

Analyte	Barium	Cadmium	Chromium	Cobalt	Molybdenum	Nickel	Tin	Mercury
Minimum	18	<0.5	7	2	<4	1	<4	0.18
Maximum	4201		71	18		20		1.5
Average	188		25	6		9		0.64
Median	200		27	7		13		0.67
Number of primary samples	1	12	12	12	12	12	12	12

Mudd (2001) also provided a review of published case studies (mainly in Wisconsin and Michigan, USA) between 1978 and 1987 of the impacts from CCA ponds on groundwater quality. The majority reported elevated concentrations of major ions in the vicinity of ponds. These included sodium, calcium, chloride, and sulfate, with considerably lower concentrations of minor ions such as aluminium, arsenic, boron, and zinc. Minor ion constituents were subject to attenuation mostly due to sorption on clays. Two studies also found that finer particles settled and accumulated at the base of ponds leading to a lower permeability.

The main constituents of interest in Mudd (2001) were restricted to sodium, sulfate, and chloride. Minor ion concentrations were not examined as part of the study; however, it is noted that solubility of minor ions was limited by the alkaline conditions and were not detected in groundwater during the period of study. While sodium and chloride were observed to be steadily increasing at selected observation points during the course of the research, sulfate was present at relatively low concentrations by comparison. This was attributed to the presence of sulfate reducing bacteria (SRB), carbon dioxide gas and the olfactory detection of hydrogen sulfide gas. The latter two gasses produced as a result of the mineralisation of labile organic matter and the reduction of sulfate by SRB mediated reactions.

At the time of writing his thesis, Mudd (2001) states that EPA Victoria had reclassified the leached ash from the Loy Yang Ash Pond as fill material (pers comm with McKinley, 1998). It is not known whether leached ash continues to be classified as fill material.

In New South Wales (NSW) coal ash repositories are located within the same sedimentary basins that contain the coal deposits[32]. It is recognised by the NSW EPA that groundwater in these sedimentary basins is naturally elevated in dissolved salts and metals and that coal ash leachate may contain the same metals and other constituents present in coal; however, discharges from coal ash repositories should be minimised and managed to reduce the risk to groundwater, surface water, and human health. Currently all CCA dams are unlined. In 2021 a report was released of a public works committee inquiry on the costs for the remediation of coal ash repositories in NSW (New South Wales Parliament, 2021). The concerns of the community relating to the cap and cover method of storing coal ash in unlined dams (some in direct contact with groundwater or surface water) is resulting in heavy metals and other pollutants escaping from coal ash dams. But the community was also aware of the cost implications of excavating coal ash from unlined dams and replacing them with lined dams. One of the recommendations was that NSW EPA commission '…a comprehensive and independent assessment of the environmental impacts of coal ash dams to provide a better understanding of the issues and to inform best practice remediation'.

8.2 International Examples

CCA management varies from country to country. Fly and bottom ash produced from coal fired power stations internationally has traditionally been either dry managed in the sub-surface or wet managed in impoundments.

Long term management of CCA in the USA is most commonly by the dry management method (EPRI, 2009). CCA management disposal sites are mainly landfill or surface impoundments. Some power plants are also permitted to dispose via discharge to local waterways (United Sates Environmental Protection Agency [USEPA] website[33]). According to the American Coal Ash Association, in 2014 approximately 48 percent of ash is recycled, however since then changes in the regulations has resulted in a decrease in recycling. The USEPA Resource Conservation and Recovery Act (RCRA) regulates coal ash as a non-hazardous solid waste and historically surface impoundments which stored ash did not have geomembranes, leachate, or stormwater management systems. Since 2016 more stringent rules on the handling and disposal of CCA were developed which allow a risk-based approach to be adopted, the Coal Combustion Residuals (CCR) Regulations 2015. Groundwater and stormwater management practices were identified to have contributed to slope failures and leachate leakages at sites in West Virginia and Pennsylvania (e.g., Quarrier ash impoundment, West Virginia). In 2008 a failure occurred in a coal ash pond in Tennessee at the Kingston fossil Plant[34]. Over 3 million m^3 of coal ash slurry was released over 120 ha. The cause of the failure was investigated and reported to be due to slippage and failure of ash and an embankment during heavy rainfall. As a result of the failure the USEPA began developing more stringent regulations which would apply to all ash ponds and dams in the USA. The CCR Regulations were published in 2015. In 2020 the USEPA published a RCRA Regulation which required all unlined impoundments to be retrofitted with liners or close by 2021.

In the coal mining districts of Germany there are several examples of sub-aqueous deposition of wastes including lignite coal ash (Schultze, 2009, 2011; & 2012). The objective of sub-aqueous ash deposition in Germany is mainly to achieve a decrease in water acidity and increase pH to near neutral conditions. Circum-neutral conditions exist naturally in soils and surface waters surrounding these acidic lakes.

There are examples of diverting river water through acidic lakes to flush and achieve neutralisation (Lessmann et al, 2003; Schultze et al, 2010), although this remedy is only short-term in some cases where acidic groundwaters reverse the neutralisation. The former coal mine at Burghammer in the Lausitz region was flooded with rising acidic groundwater to form Lake Bernstein (Merkel et al, 2005 & Koch et al, 2008). About $26x10^6$ m^3 of CCA was deposited into the flooded mine for lake neutralisation from 1970 to 1990. During 2000 to 2002 a resuspension of the settled ash was tested and was demonstrated to increase the pH. The pH of the lake water increased from pH 2.9 to a range pH 5.3 to 9.2 while sulfate and metals (e.g., aluminium, manganese, iron, and zinc) decreased in concentration due to complexation and mineralisation reactions; however, there was no change in minor ion concentrations such as copper, cobalt, and chromium over the study period.

In some European countries such as Denmark and the Netherlands, all the ash is recycled for use in construction and road projects where it can replace raw materials such as sand and sub-base (gravel). Trace metals and salt (NaCl) can also be recovered from bottom ash. China also provides subsidies to promote coal ash recycling, achieving recycling rates of 60 percent, according to the Asian Coal Ash Association[35]; as a result, CCA management and waste disposal information is limited in these countries.

[35] https://www.asiancoalash.org/ accessed 14th February 2022

There are examples of the subaqueous capping or covering of dredged sediments where the capping is used to manage the advective flux of heavy metals within the dredged sediments (Palermo, 1998). This approach has been used in the USA (e.g., Long Island Sound), Netherlands (e.g., Rotterdam Harbour), and Japan (e.g., Hiroshima Bay). While the capped material was not fly or bottom ash, it did consist of dredged sediments containing elevated heavy metals. Capping (the construction of a cover layer consisting of solid material on top of the waste) results in longer diffusion paths, eventually decreasing the diffusive transport rate of constituents to practically zero. Capping also prevents the resuspension of waste in the water column. The USEPA has adopted the technique of capping to remediate or isolate contaminated sediments in a subaqueous environment. The objective of using a cover is to fulfill the following:

A. Physical isolation of the sediment;
B. Sediment stabilisation, in terms of preventing erosion and resuspension; and
C. Reduction of dissolved contaminant flux.

Several models have been developed to calculate contaminant advective mass flux (Alshawabkeh et al, 2005; Eek et al, 2007; and Labianca et al, 2022). In addition to non-linear advection and diffusion, the models consider the effects of consolidation and pore pressure dissipation influences on contaminant migration. For the scenarios discussed in these papers, the dredged sediments are still saturated when covered. The authors found that sediment consolidation (from the cap weight) contributed to significant contaminant flux and accelerated the contaminant breakthrough by orders of magnitude. Not surprisingly, the moisture content (and sediment compression) was found to be the most sensitive parameter in decreasing the contaminant flux. It would appear that the capping of a material intended for sub-aqueous disposal should be conducted when the material has been drained and excess moisture removed by compaction prior to capping.

8.3 Summary

In summary, the management of CCA and leachable ash in sub-aqueous settings differs both nationally and internationally. In countries where the surrounding catchment (soil and surface water) is naturally less acidic than the acidic water bodies within them, these water bodies have been amended with alkaline CCA to achieve neutral conditions and lower concentrations of major ions and acid producing metals. This approach can however be short-lived and may not affect trace metal concentrations. Depending on the leachable characteristics of CCA, surrounding CCA in low permeability materials is beneficial in lowering the risk of mobilisation of major and minor ions which can affect surrounding surface quality and groundwater quality. Prior to encapsulating with low permeability materials, the ash should also be dewatered to achieve a low moisture content.

Prior to consolidation within the mine pit, the Anglesea CCA was leached in ash ponds over many years, the result of this process is a leachable ash with a low leachable fraction of major and minor ions that are normally associated with leachable ash and ash leachate (**Section 6**). The leached ash has been dried and the minimal amount of dredged leachable ash was dewatered and consolidated before being covered by clay-rich material. The surrounding materials are low permeability (on average less than $1x10^{-9}$ m/sec) and have been placed by semi-engineered methodologies in most areas surrounding the CLA area (berm, haul road and cover), refer to **Section 7**.

9 Numerical Modelling and Particle Tracking

9.1 Introduction

This section presents the conceptualisation used to support hydraulic modelling of recovering groundwater and the results of hydraulic modelling and particle tracking using GeoStudio SEEP/W software. The results have been used to inform on the potential conservative migration of constituents within CLA porewater as groundwater and the mine water body inundates the CLA and surrounding fill material.

9.2 Aim and Objectives

The CLA is covered with low permeability clay (referred to as the clay-rich layer) and will be inundated with water as the water body elevation increases over time. Separate long term groundwater modelling is currently underway to determine the final steady-state water level; however, this is dependent upon the final water fill strategy and is expected to be approximately +5.5 mAHD. The modelling to support the leached ash assessment has been used to simulate a “fast fill” strategy whereby the rising water body level increases faster than the surrounding groundwater elevation and in turn, groundwater flow into the model domain and CLA is estimated. The migration of water particles is simulated to be conservative (not subject to attenuation or retardation) constituent for the purposes of the subsequent risk assessment. The aim of the modelling is to provide information on the predicted hydraulic performance of the clay-rich layer.

The following information has been collated to develop the conceptual site model (CSM) related to the CLA and clay-rich layer:

1. Geometry of CLA area;
2. Characteristics of the CLA, clay-rich layer and fill material, including:
    a. Geotechnical properties of CLA and clay samples;
    b. Leaching procedure tests on CLA and clay samples; and
    c. Dispersivity characteristics of the CLA and clay.

The development of a CSM using the physical and hydrogeological characteristics of the materials within the model domain have been used to construct a numerical model using the finite element software package SEEP/W, which is able to simulate flow in unsaturated and saturated profiles.

The overall objective is to use SEEP/W to simulate:

- Hydraulic behaviour of rising water body and groundwater levels and potential groundwater seepage into the fill material under steady-state and transient conditions; and
- Particle tracking to observe movement of particles representative of a conservative (not subject to attenuation or retardation) constituent within the model domain.

9.3 Field Investigations

Consolidation of the leached ash material from the ash storage ponds was completed in 2017 within the south-eastern corner of the pit between RL -15 mAHD and -8 mAHD over an area of approximately 4.6 ha (**Figure 5**, attached). The CLA was covered with at least 1 m of clay-rich material to provide a hydraulic separation layer between the CLA and the surrounding fill material. Additional fill material was re-deposited in the pit in the vicinity of the CLA which consists of re-worked clay, silt, and sands from DBF and BF. Refer to **Section 6** and **Section 7** for further detail on the leached ash, clay-rich cover layer, and fill material characteristics.

Drilling and sampling were carried out in the vicinity of the CLA area in September 2021 and also in June/July 2022. Samples recovered from this investigation were submitted to Golder Geotechnical Laboratory and GroundScience for geotechnical testing. Geotechnical testing comprised of saline and de-ionised water permeameter tests, moisture content, and dry density. The geotechnical parameters from the laboratory tests are summarised in **Table 10** and **Table 14** (attached). Bore logs have been provided in **Appendix G**. The bore logs provide visual and textural characteristics of the CLA, clay-rich material and the fill material.

These data provide the basis for development of the model input parameters discussed in the following sections.

9.3.1 Dispersivity /Reactivity

Soil testing was carried out on samples to assess the Emerson Class Number. This test indicates the degree of dispersivity or reactivity displayed by the samples when in contact with de-ionised water and provides an indication of the leached ash (and surrounding material) stability under saturated conditions. The results are presented in **Table 11** (attached). The results show that most of the samples did not disperse in de-ionised water apart from two samples that showed a slight to moderate reaction.

9.3.2 Lithological Characteristics

Lithological characteristics have enabled a detailed understanding of the in-situ geology and the spatial distribution of the reinstated fill material. For this technical assessment only the geological units relevant to this CSM are discussed in detail within this section and **Section 9.4**. These units are summarised in **Table 9-1** and **Figure 9-1** below.

Table 9-1 Geological Units – Conceptual Site Model

Period	Geological Unit	Description	Approximate Thickness
Tertiary	DBF	Marine deposit of fine-grained micaceous and carbonaceous silts and silty clays comprising Anglesea Formation and Salt Creek Formation in the vicinity of the former Anglesea mine.	Along the coastal stretch between Aireys Inlet and Anglesea and stretches inland towards the Bells Beach anticline. The Demons Bluff Formation is up to 20 m thick. Within the Anglesea coal mine area, the DBF consists mainly of sandy clay with localised silty clays and clayey sands.
	BF	The BF has historically been reported to be a member of both the UEVF (upper most unit) and the DBF (lower most unit). The formation consists of 1-3 m thick-coarse-grained sand-channel units with interbedded minor clay, shale, and carbonaceous siltstone.	In the Anglesea coal mine, the Boonah Formation is up to 32 m thick with the basal permeable sections (1-3 m thick) extending laterally up to 50 m (e.g., representative of disconnected “shoe-string sands”). Mainly consists of sandy and silty clays.
	EVF	Deposited in a non-marine lacustrine or deltaic environment and subdivided into three distinct units.	

Period	Geological Unit	Description	Approximate Thickness
	UEVF	The UEVF comprises the upper part of the EVF. Clay, silty clay, silt and fine to medium grained sand sequences with minor fine gravel lenses. Brown coal seams are common in the top of the sequence, with the A Group coal seam mined within the former coal pit.	Unit up to 250 m thick in Anglesea Syncline. Coals from this unit were formerly mined by Alcoa (generally <50 m thick).

Table Notes:
EVF = Eastern View Formation
UEVF = Upper Eastern View Formation

In contrast to the local DBF&BF geology in the Anglesea area, the Anglesea mine facies comprises clays which are sandier and siltier with localised coarse sand as observed in **Appendix G**. The Middle Eastern View Formation (MEVF) and Lower Eastern View Formation (LEVF) underlie the Upper Eastern View Formation (UEVF). Due to their depth (located >250m below the site), these are not relevant to this CSM and are discussed no further.

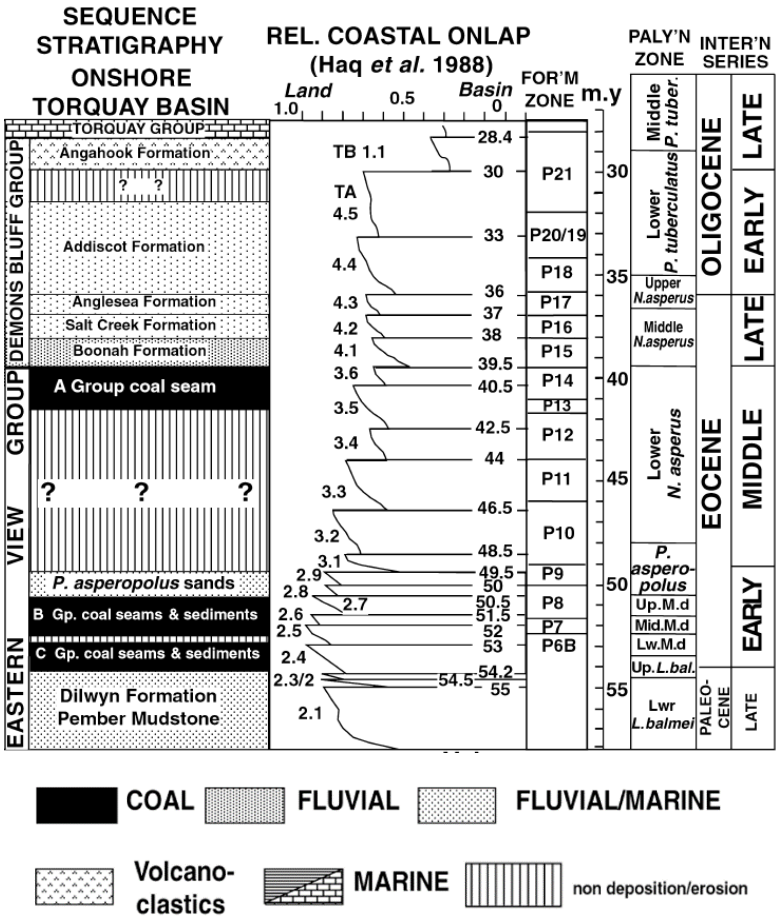

Figure 9-1 Stratigraphic Sequence of the Onshore Torquay Basin (Holdgate et al., 2001)

The DBF and BF are discussed in more detail below as these lithologies have been reworked to form the fill material which is the main material within both the CSM and the SEEP/W model domain. The A Group coal seam and basal clay of the UEVF form the base of the CSM, with additional detail provided below.

9.3.2.1 Demons Bluff Formation

The Anglesea Formation is interpreted to represent a complex of low-energy fluvial channel and braided sheet-like sands deposited on a lower coastal plain, which periodically became higher energy channel-like features with increased downcutting into earlier deposits. The upper highwall succession in the Anglesea coal mine comprises up to a 20 m thick red to purple carbonaceous and pyritic siltstone to fine sandstone. At least one short-duration marine flooding event (preserved as pyritic shale containing marine dinoflagellates) followed the infilling of the basal down-cut surface. The remaining facies preserve low-energy fluvial channel and braided sheet-like sandstone and shale-filled meander loops.

The Salt Creek Formation is on an erosional contact that can be linked across the mine face as a series of stratigraphically connected sandstone channels. The disconformity contact is a 0.1 m shale layer between cross-bedded micaceous fine quartz sandstone of the top Salt Creek Formation below, and the homogenous micaceous fine quartz sandstone of the overlying Anglesea Formation. Other more localised low-angle channels occur at the base of overlying units. Samples shown in **Figure 9-2** indicate where pervasive limonite cements form ferricrete layers in the coarser grained channel bases. Red limonite staining appears to increase rapidly over the top 5 m of the Formation and is associated with weathering from the present ground level. Interbedded carbonaceous shale and laminated siltstone units immediately overlie the basal channel layers and form a 5 to 7 m thick unit along the mine face. The basal silty shale of this unit is pyritic and contains evidence indicative of a short-duration marine transgression.

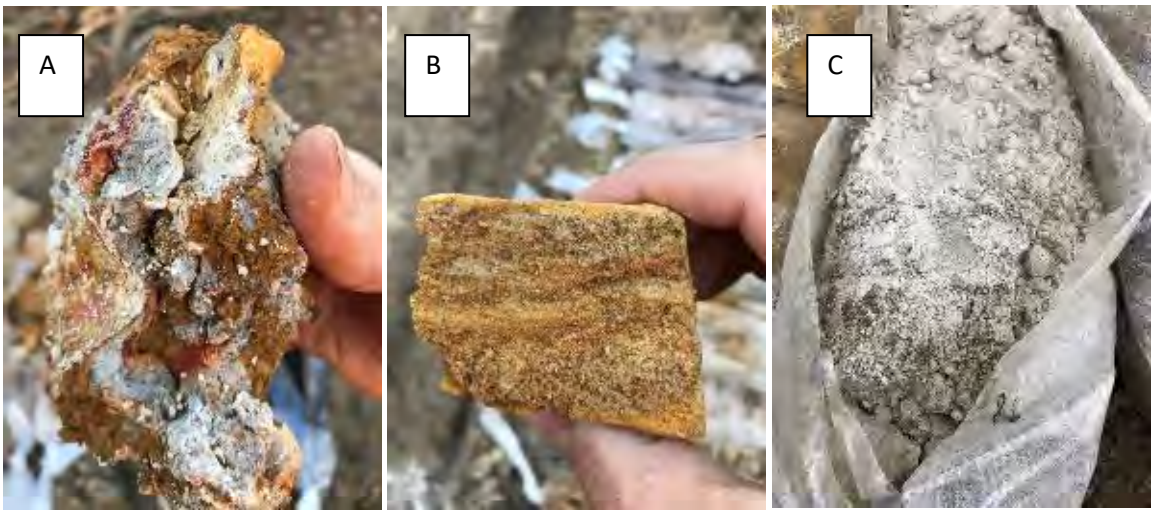

Figure 9-2 Demons Bluff and Boonah Formations (a) Salt Creek Formation, (b & c) Boonah Formation

9.3.2.2 Boonah Formation

Unconformably overlying the A Group coal seam (main Coal Seam) in the Anglesea coal mine, and in nearby bores, are clean sandstones with minor carbonaceous shale, clay, and coal. Down dip the sandstones increase from 10 m to 70 m in thickness. These sediments belong to the Boonah Formation (Holdgate et al 2002; Smith 1998). The basal coarse channel gravels and sandstones overlie the A Group coal seam at an erosional angular unconformity. The unit is thickest in the Anglesea Syncline, which thins to the north-east and south-west outside the synclinal area. The unconformity surface defines the upper boundary of the EVF; due to this unconformity, the Boonah Formation is placed in the DBF rather than the EVF.

In the Anglesea coal mine the Boonah Formation is up to 32 m thick, comprising fine to coarse-grained sand-channel units in the upper and lower 10 m, with interbedded shale and carbonaceous (leafy) siltstone occurring in the middle 10 m to 12 m (**Figure 9-2**). The basal coarse facies are exposed mainly in the central part of the Anglesea Syncline and onlap the top of the A Group coal seam to the west.

Cross-cutting, fining-upward channel units range between 1 m and 3 m thick and extend laterally from 30 m to 50 m. Finer grained overbank deposits are poorly represented, but where preserved, consist of planar-laminated carbonaceous siltstone.

9.3.2.3 Upper Eastern View Formation

A Group Coal Seam

Most of the significant coal seams of the EVF occur in the upper parts of the Formation. This is interpreted to be the UEVF (EHS Support, 2022). The uppermost and thickest A Group coal seam is up to 36 m thick and locally splits near the base into the A1 and A2 seams.

Basal Clay

The Basal Clay underlies the mined A Group coal seam and is approximately 1-4 m thick, refer **Figure 9-3**. Mining One conducted a field investigation in early 2016 of the Basal Clay, comprising three test pits and two drill holes. A factual report (Mining One, 2016) has been prepared which incorporates the findings. In the vicinity of the consolidated leached ash area the Basal Clay is approximately -40 mAHD and 1-2m thick.

Figure 9-3 Site Photos Showing the Main Coal Seam Exposure (A) and Basal Clay (B)

9.4 Hydrogeological Characteristics

9.4.1 Fill Material

Groundwater monitoring bore, DBG MB6, is located approximately 500 m north-west of the consolidated leached ash area. This bore is screened within the fill material which consists of re-worked clay, silt. and sands from DBF and BF. Groundwater recovery in the vicinity of this bore has been measured since December 2020 and the water table was reported as -16.62 mAHD in February 2022 (**Table 21**, attached).

9.4.2 Demon Bluff Group

The DBG comprises the DBF and the underlying BF.

The DBF includes the Angahook Formation, Addiscot Formation, Anglesea Formation, and Salt Creek Formation (Holdgate, et al., 2001). In the greater Anglesea region only the Salt Creek Formation and Anglesea Formation are present (**Figure 9-1**).

The BF is also present in the area and forms the base of the DBG and overlies the UEVF at an erosional angular unconformity (Holdgate, et al., 2001). The formation is distinctly different from other members of the DBF and comprises cross-cutting coarse-grained sand-channels in the lower and upper units, with shale and carbonaceous siltstone interbedded with lenses of fine-grained sandstone (Holdgate, et al., 2001). BF is well exposed at the Alcoa Coal Mine and is expected to have highly variable aquifer properties consistent with the heterogenous horizons.

Groundwater conditions at the Alcoa Coal Mine indicate that the DBF and BF near to the coal mine are largely unsaturated and discreet perched aquifers are common (in the vicinity of the former power station). For the saturated DBF bores located nearer the former power station, groundwater levels generally fall within the -4 to +4 mAHD range, which was the same range previously reported for the unconfined aquifer prior to Alcoa development (Hancock, 1967). If present, groundwater flow is expected to follow topography as well as being influenced by the mine pit.

Estimates of hydraulic conductivity in the DBF (likely the BF) were calculated from slug tests at four monitoring bores, MW4, MW10, MW11, and MW22 (Beattie, 2003). A summary of the results are presented in **Table 9-2**.

Table 9-2 Slug Test Summary (DBF)

Bore	Lithology	Bore Depth (m)	2015 Standing Water Level (mAHD)	2015 EC (µS/cm)	Hydraulic Conductivity (m/sec)
MW4	Silty Clay	3.5	5.7	7,170	$1.04x10^{-6}$
MW10	Silty Sand	5.6	8.4	2,630	$1.18x10^{-7}$
MW11	Clayey Gravel	5.5	8.3	3,260	$3.1x10^{-6}$
MW22	Silty Clay	11.8	1.6	3,410	$6.9x10^{-7}$

Table Notes:
m = metres
AHD = Australian Height Datum
µS/cm = microseimens per centimetre
EC = electrical conductivity

To support the values provided in **Table 9-2**, Domenico and Schwartz (1990) have published values for clay ($5x10^{-9}$ to $1x10^{-11}$ m/sec), silt ($2x10^{-5}$ to $1x10^{-9}$ m/sec), and sand ($6x10^{-4}$ to $9x10^{-7}$ m/sec). Hydraulic conductivities listed in Hazleton and Murphy (2016) have published values for clay ($1x10^{-9}$ m/sec), silt ($3x10^{-6}$ to $1x10^{-9}$ m/sec), and sand ($2x10^{-4}$ to $3x10^{-8}$ m/sec). Beattie (2003) values fall within the range of the Domenico and Schwartz (1990) and Hazleton and Murphy (2016) values. A slug (falling head) test was conducted on groundwater monitoring bore DBG MB6 in May 2022. Analysis of the test indicates a hydraulic conductivity of $1.16x10^{-7}$ m/sec (**Appendix I**).

Hydraulic conductivity values have also been sourced from the Anglesea numerical model (GHD, 2022) that is currently in development and under separate independent peer review by DELWP Technical Review Panel.

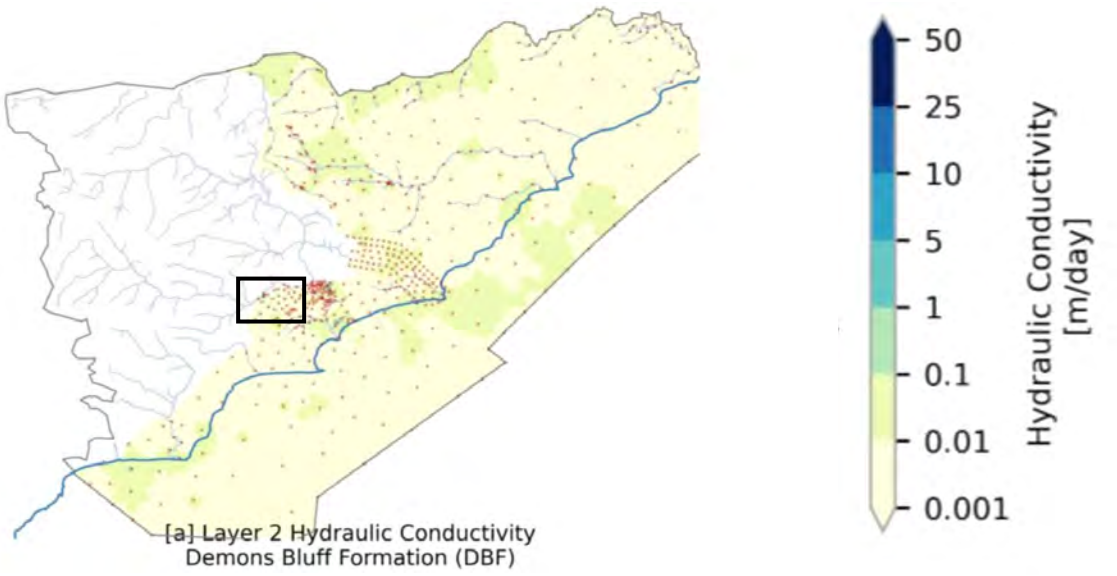

Figure 9-4 Demons Bluff Formation Horizontal Hydraulic Conductivity (GHD, 2022)

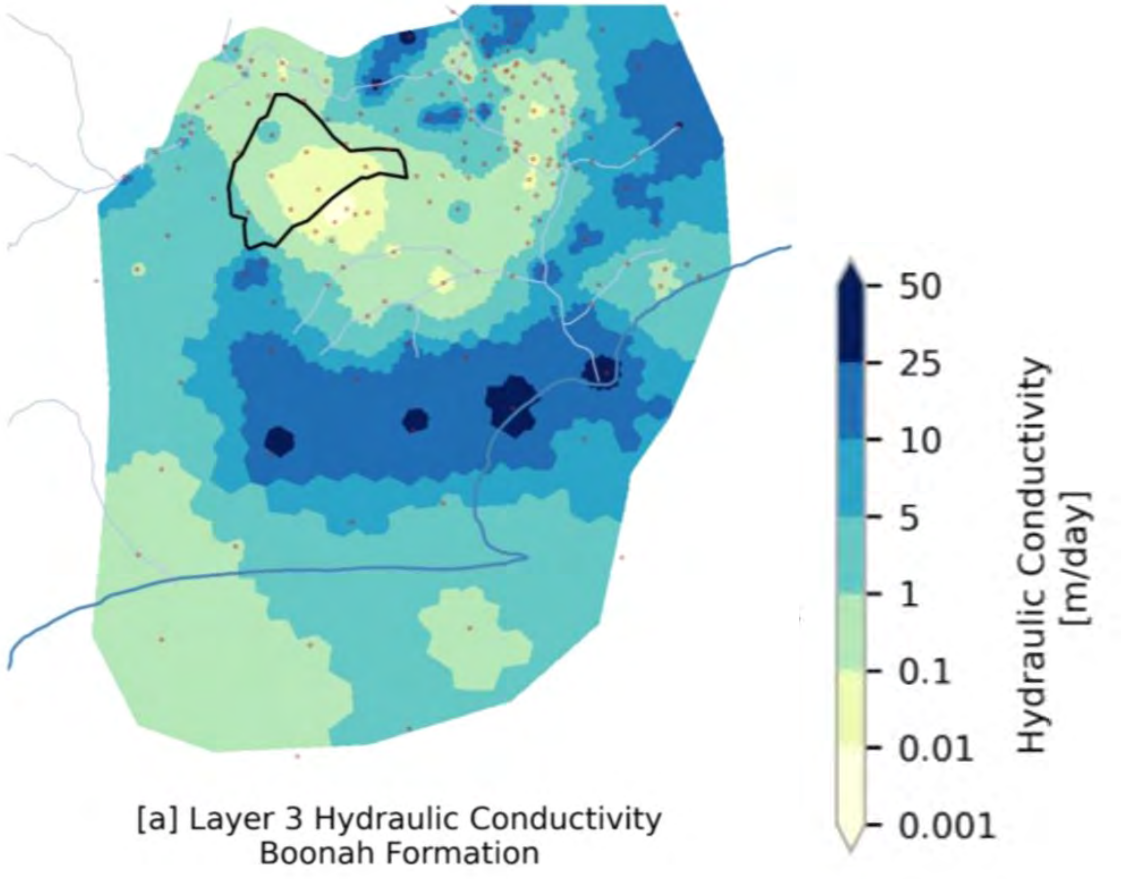

Figure 9-5 Boonah Formation Horizontal Hydraulic Conductivity (GHD, 2022)

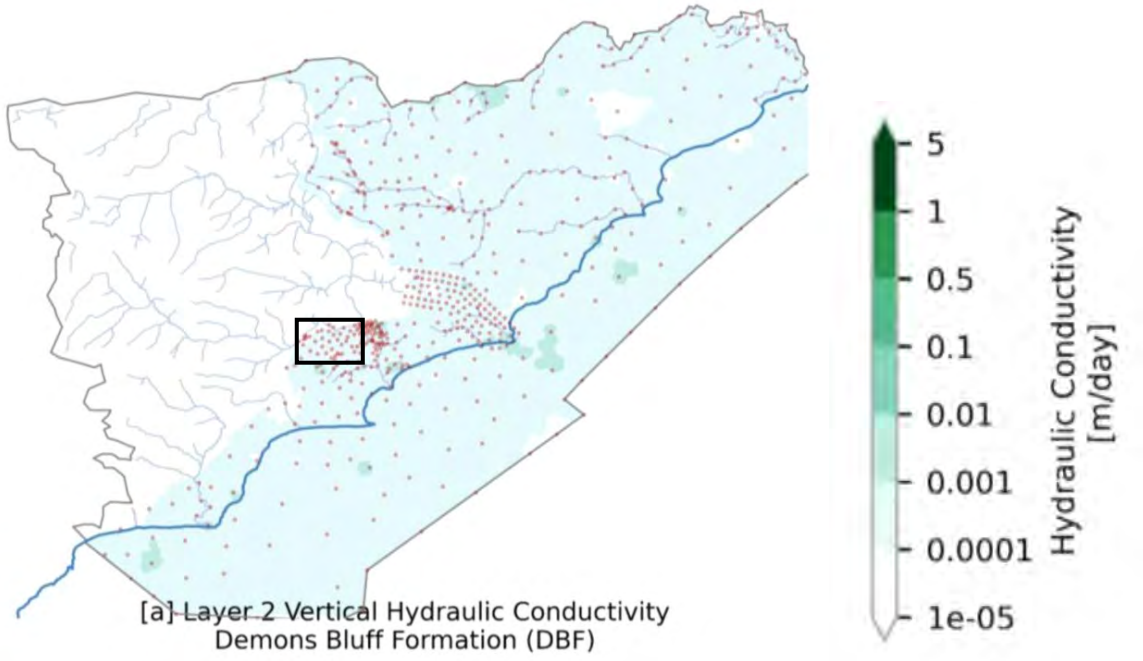

Figure 9-6 Demons Bluff Formation Vertical Hydraulic Conductivity (GHD, 2022)

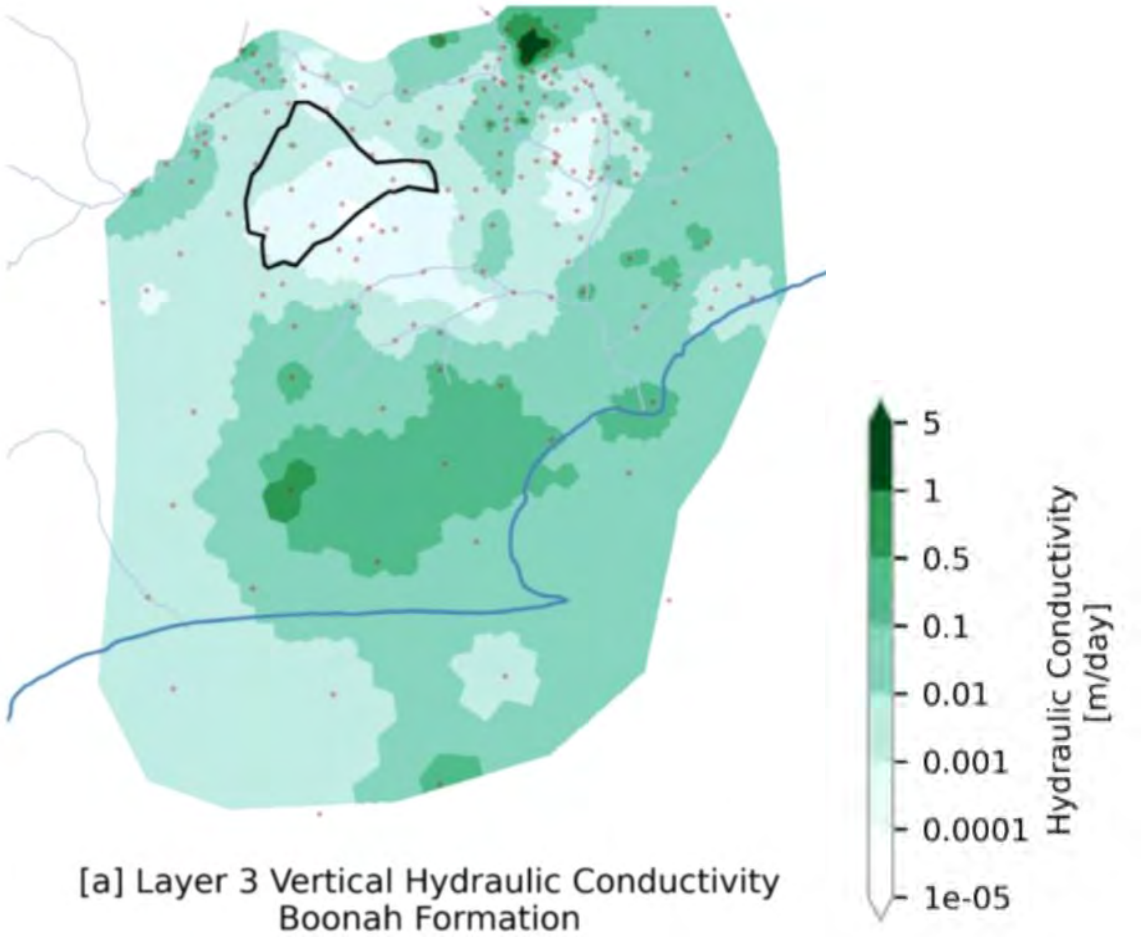

Figure 9-7 Boonah Formation Vertical Hydraulic Conductivity (GHD, 2022)

The horizontal hydraulic conductivity values in the DBF range between $1.16x10^{-6}$ to $1.16x10^{-7}$ m/sec. The BF horizontal hydraulic conductivity values range from $1.16x10^{-5}$ to $1.16x10^{-7}$ m/sec. The vertical hydraulic conductivity values in the DBF range between $1.16x10^{-7}$ to $1.16x10^{-9}$ m/sec. The BF vertical hydraulic conductivity values range from $1.16x10^{-8}$ to $1.16x10^{-10}$ m/sec (GHD, 2022). The anisotropy between the minimum and maximum horizontal and vertical hydraulic conductivity ranges between 0.01 and 0.00001.

9.4.3 Eastern View Formation

Hydrogeologically, the EVF can be sub-divided into three main units;

- UEVF;
- MEVF; and
- LEVF.

In the vicinity of the mine pit, the UEVF is considered to be a confined aquifer and is approximately 250 m thick. It consists of clay, silty clay, silt, and fine to medium-grained sand sequences with minor fine gravel lenses. Brown coal is also common in the top of the UEVF sequence. Evidence of different potentiometric heads exists (through site observations by Hancock (ibid), as well as in recent installation of observation bores) throughout the profile. A bore drilled near the former power station, M274, was believed to be completed in the middle section of the UEVF. Small artesian flows (hydraulic head of ~+4mAHD) were recorded from a sand lens at a depth of 138 metres below ground level (mbgl) or approximately - 120 mAHD. This elevation provides a good indication of the pre-mining UEVF (upper sands) potentiometric surface (EHS Support, 2022).

Alcoa ceased abstracting groundwater from the UEVF in 2016. Since this date groundwater levels have been recovering within the UEVF and the water table within the upper sands of this unit are approximately -20 mAHD to -16 mAHD (as of November 2021) and rising at a rate of approximately 0.2 m per month. Refer to EHS Support (2022) for more detail on the hydrogeology of the UEVF.

Figure 8 (attached) illustrates a conceptualisation of the in-situ geology and hydrogeology in the vicinity of the mine pit.

9.5 Consolidated Leached Ash Risk Assessment

In accordance with Part 3 Division 6 Section 44 of the Mineral Resources Sustainable Development (Mineral Industries) Regulations (2019), Alcoa has identified potential mining hazards and assessed risks associated with covering and submerging the CLA area located in the south-east corner of the mine. This process involved several steps, consistent with those outlined in 'Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS' **Appendix B** (December 2020 version 1.3) (Victoria, 2020) provided by the Department of Jobs Precincts and Regions.

A summary of the findings of the Leached Ash Risk Assessment is provided in **Section 10**. Evaluation of the significance of the consolidated leached ash deposit in terms of environmental risks and commensurate management necessary to minimise risks to the environment which has been conducted in accordance with an appropriate risk management framework.

9.6 Conceptual Site Model

The CSM relates to the CLA, the clay-rich layer and the surrounding fill material and has been developed to be representative of existing and future conditions as groundwater levels recover in the fill material and as the water body is expected to inundate the area above the CLA.

The CSM was developed sequentially as three scenarios:

1. Scenario 1 – water body surface elevation of -17.4 mAHD, representative of current conditions;
2. Scenario 2 – increase in water body surface elevation from -17.4 mAHD to 5.5 mAHD under natural fill conditions, and
3. Scenario 3 – increase in water body surface elevation from -17.4 mAHD to 5.5 mAHD under fast fill[36] conditions.

The water body level of 5.5 mAHD has been conservatively adopted for the conceptual model, however the final water level will depend on the hydrogeological response in the catchment and the long-term water strategy. Fast fill refers to additional water to supplement natural groundwater and rainfall recharge. Surface water in-flows to the water body such as discharge water from the 2021 groundwater pumping test could be used to achieve the fast fill option.

The CSM geology assumes that the model domain is represented by fill material (reworked DBF and BF overburden), which was known to be used as back-fill during the long-term operation of the mine. Backfilling within the mine footprint has occurred since commencement of mining in the 1960's to the present day (**Figure 3** and **Figure 4**, attached).

A bench of fill material in the south-eastern corner of the mine pit has been placed where the A Group coal seam was worked out and subsequently covered by the fill material. As part of the operation of the mine, the coal was continuously worked out to the top of the basal clay leaving only minor coal spoil, and fill material was progressively backfilled to cover the basal clay. The top of the basal clay is approximately -40 mAHD in the vicinity of the consolidated leached ash. Leached ash was discharged at an elevation of -15 mAHD and consolidated within the fill material bench to -8 mAHD at an approximate thickness of 4 m, based on the topography of the leached ash consolidation area at the time. The clay-rich cover material was then laid over the top of the CLA (laterally covers the same area as the CLA) and machine rolled/compacted to a depth of 1 m or greater (**Figure 1**, attached).

9.6.1 Scenario 1 – Current Condition

Scenario 1 represents the current conditions in the vicinity of the CLA. The water body level lies at -17.40 mAHD (surveyed March 2022). The water body has developed through the rebound of groundwater in the vicinity of the mine pit, in addition to rainfall and surface water run-off, including water from the recent groundwater pumping test, after groundwater abstraction from the UEVF ceased in March 2016. The maximum depth at the north centre point of the water body is approximately -45 mAHD. **Figure 9-8** is a conceptualisation of Scenario 1 in the eastern portion of the water body and fill material. The west-east (A-A') transect illustrates the relationship between the water body, the CLA and the clay-rich layer covering the top of the CLA. Fill material (consisting of reworked overburden material) extends up to 900 m from the water body towards the east. Groundwater within the fill material is reported at an elevation of -16.62 mAHD (groundwater

[36]Fast fill equates to 1.5 GL/yr of abstracted groundwater to achieve a water body surface elevation of 5.5 mAHD.

monitoring bore DBG MB6, 1 February 2022). Groundwater monitoring bore DBG MB6 is located approximately 540 m north-west of the CLA. This bore is screened within the fill material and has been adopted to represent the fill material groundwater elevation at the eastern boundary of the model.

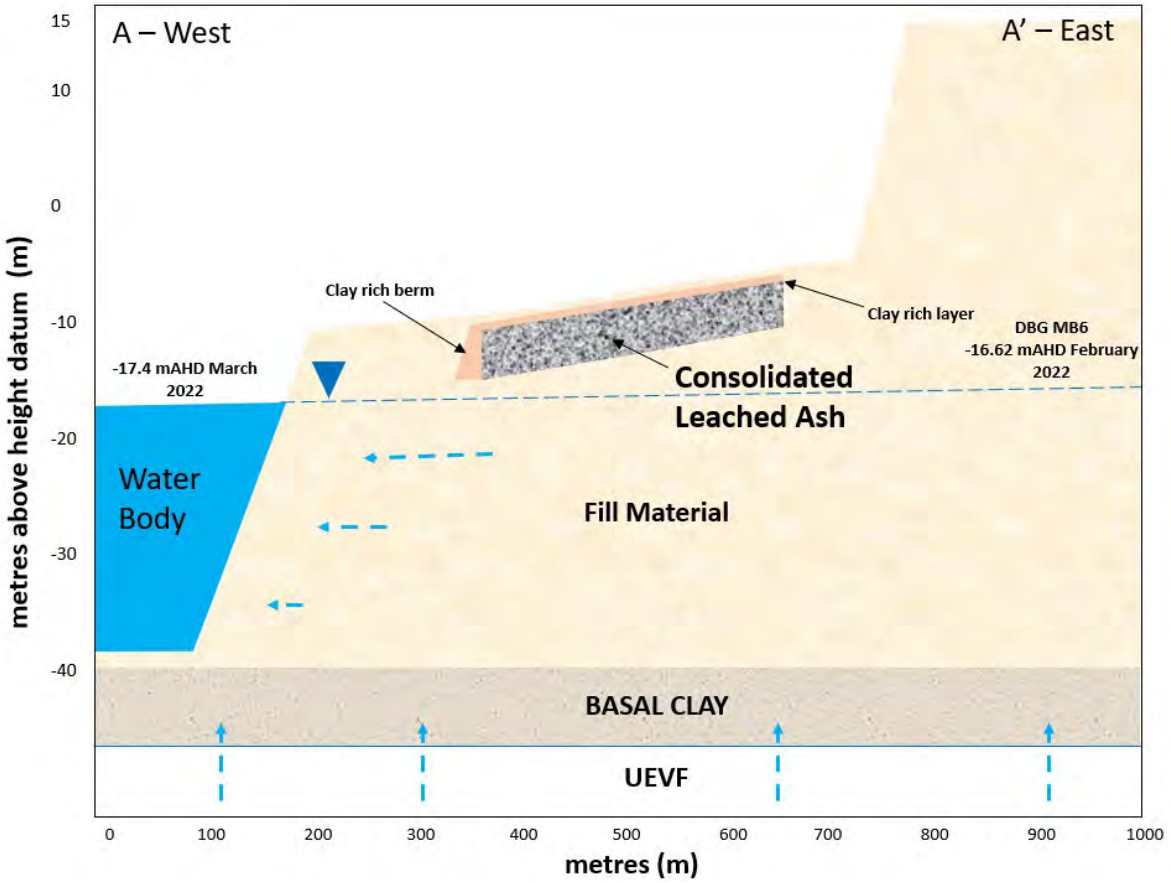

Figure 9-8 Scenario 1 Representative of Current Conditions

9.6.2 Scenario 2 – Natural Fill

Scenario 2 is representative of an increase in water body elevation from -17.4 mAHD to 5.5 mAHD. This water level has been adopted for the conceptual model; however, the final water level will depend on the hydrogeological response in the catchment and the long-term water strategy (**Figure 9-9**). Groundwater flow in this scenario is towards the water body, with the water body predicted to behave as a long-term groundwater sink (GHD, 2022). The water body development in the hydrogeological conceptualisation is based on the rising groundwater levels within the UEVF as the groundwater pressures recover. A combination of natural groundwater recovery, direct rainfall and local catchment runoff will result in the formation of the water body between 50 to 100 years (EHS Support, 2018). When the water body reaches 5.5 mAHD, evaporative losses from the surface of the water body will maintain a groundwater flow in a westerly direction into the water body. The water body is anticipated to behave as a long-term groundwater sink.

Due to the permeability contrast between the CLA /clay-rich layer and the surrounding fill material, groundwater is more likely to flow preferentially through the fill material rather than the mass of CLA and clay-rich layer. The CLA and clay-rich layer will saturate over time; however, since its hydraulic conductivity is orders of magnitude lower than the fill material, throughflow will be proportionally lower in the CLA and clay-rich layer.

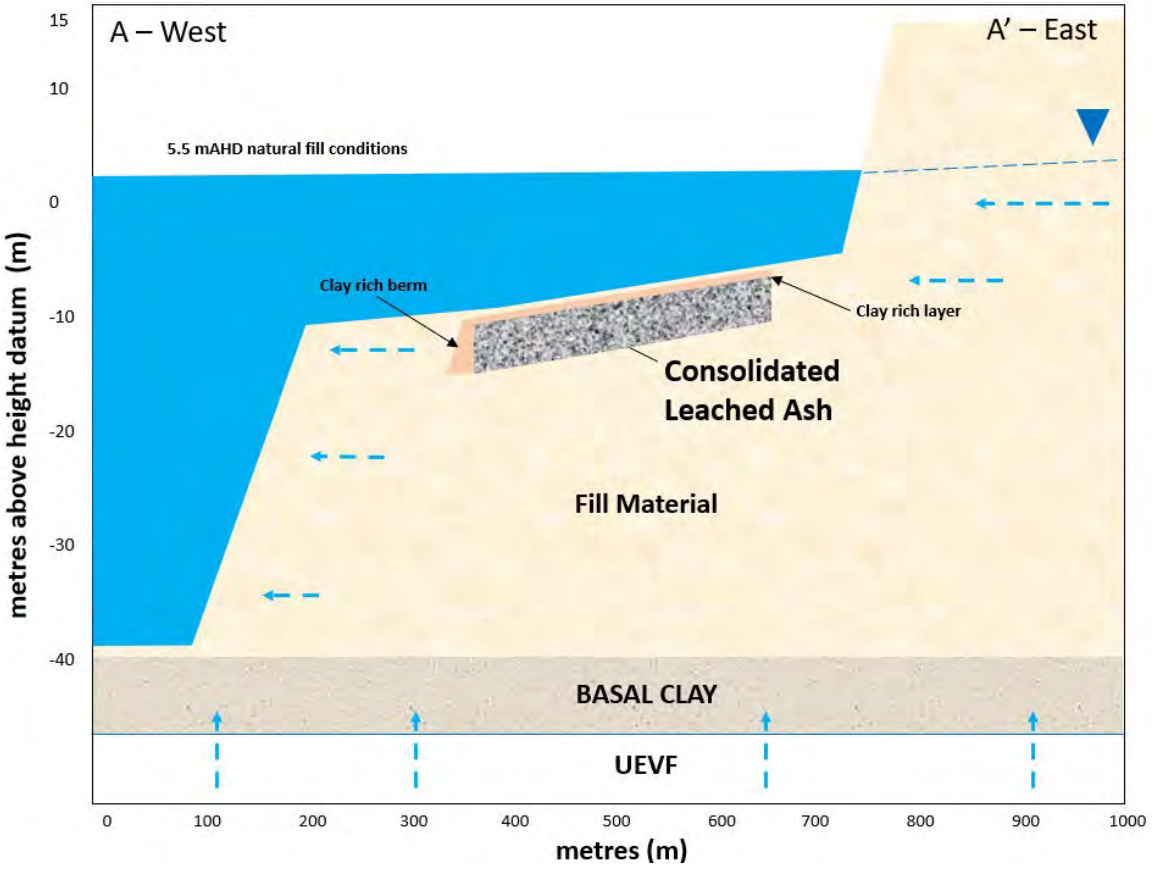

Figure 9-9 Scenario 2 Future Water Body Level (5.5 mAHD) Under Natural Fill Conditions

9.6.3 Scenario 3 – Fast Fill

Scenario 3 is representative of the development of the water body under fast fill conditions. During filling the water body is anticipated to lose water locally over a limited distance for a period of time into the surrounding geology; however, once at steady state, the water body is predicted to behave as a long-term groundwater sink (GHD, 2022). This includes groundwater movement from the UEVF to the water body; it is also supported by numerical modelling undertaken in 2017 and 2019 (GHD) and preliminary modelling using the revised Anglesea Groundwater model which has been deemed fit for purpose by an independent technical review panel (appointed by DELWP). DELWP appointed an independent technical review panel consisting of expert modellers, ecologists, acid mine drainage and groundwater engineers. Their review concluded that the conceptualisation and revised Anglesea Groundwater model is deemed fit for purpose, with one of the objectives of the model being to understand pit water/groundwater interactions. Analytical modelling (using the laboratory derived parameters of the basal clay) also suggested that during the filling of the water body the level remained 2 m higher than the groundwater level and it would take about 7 years for any pressure impacts to migrate through 2 m of Basal Clay. At steady state evaporation will be the primary water loss mechanism from the water body. The artesian heads of the UEVF were also found in the basal sand lenses. Drilling in the 1950/60 found evidence of lithostatic pressure (i.e., as drilling progressed through each coal and clay seam, the pressure would spike). The basal sand lenses are under greater pressure than the shallower sand seams.

The final water body elevation is 5.5 mAHD (as in Scenario 2); however, the time predicted to fill to this level is over a much shorter time frame due to additional water input (**Figure 9-10**).

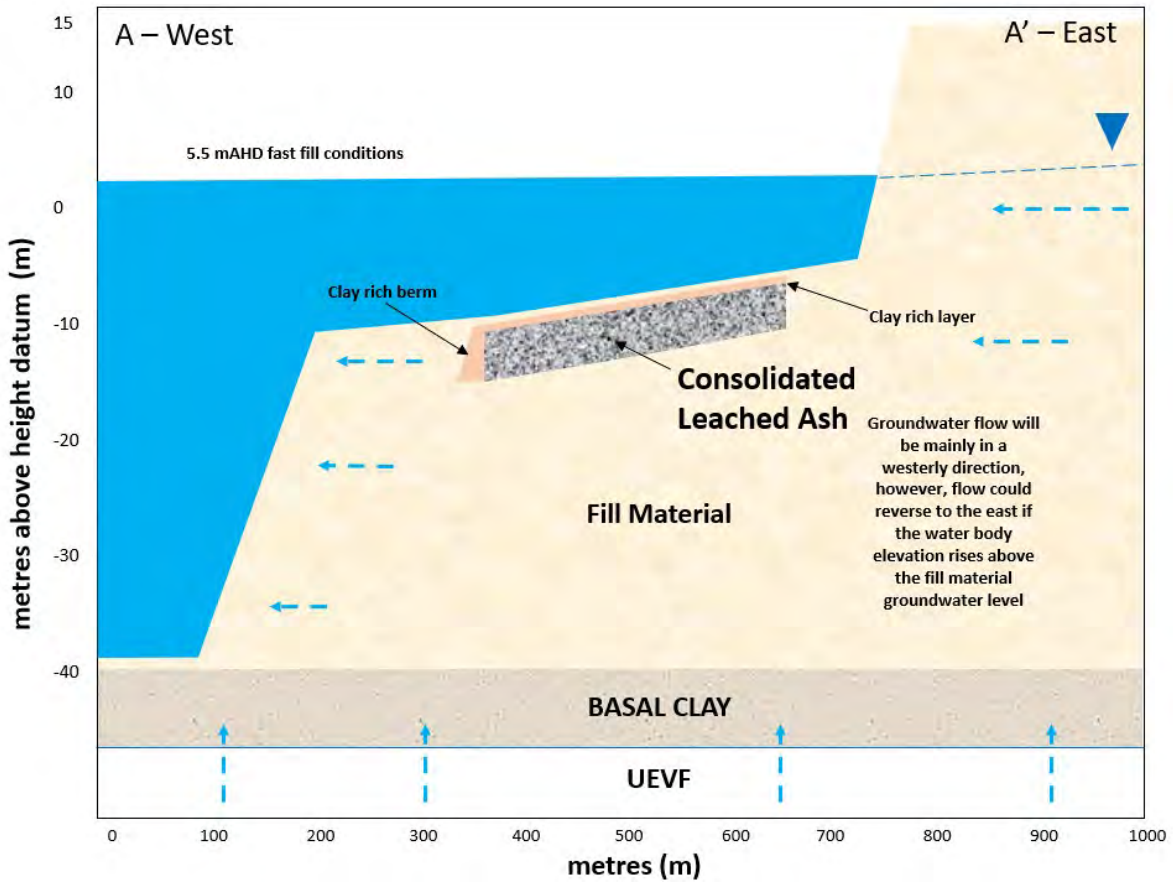

Figure 9-10 Scenario 3 Future Water Body Level at 5.5 mAHD using Fast Fill Conditions[37]

9.7 Simple Analytical Calculation

A simple analytical calculation is presented in this section as a high-level assessment of potential travel distances based on simple advective principles. All leached ash vertical permeabilities (n = 7) are all lower (less) than $1x10^{-9}$ m/sec (laboratory measurements). Assuming a highly conservative 1:1,000 horizontal anisotropy (i.e., groundwater flows 3 orders of magnitude faster in the horizontal direction than vertical) and using the very conservative analytical Darcy law assessment with a porosity of 20% and assuming the water body fills in 1 year (i.e., the water level is approximately 15m above the highest RL of the CLA area). In 12 months a particle of water has the potential to travel only 11 m. If the horizontal permeability of the formation was an order of magnitude higher (to $1x10^{-5}$ m/s; or approximately 1 m/day, which is representative of a sand), water will migrate only up to 111 m. In any case this is less that the distance from the CLA area to the licensed mine boundary[38] as the undisturbed DBF is approximately 400 m (east) and 200 m (south) of CLA material.

A numerical model (SEEP/W) has been used to explore the hydraulics of the model domain in greater detail.

[37] Note: The groundwater flow arrows are depicted in a westerly direction (end of simulation) however there will be an easterly flow for a period of time (refer to **Section 9.9**)

[38] The licenced mine area will remain in place for as long as it needs to mitigate any risks and Alcoa is in a position to surrender the licenced area to the State. This can only be done once the State accepts that Alcoa has met all of its obligations and reduced long term risk to an acceptable level.

9.8 Model Selection

SEEP/W has enabled a transient assessment of the development of the water body and the change in pore water pressure using variable hydraulic boundary conditions within the fill material and CLA/clay-rich layer. SEEP/W uses a finite element mesh and boundary conditions and has the functionality to consider the change in pore water pressures in response to changing head conditions and incorporate multiple boundary conditions within a 2-dimensional model environment. Multiple-particle-tracking in SEEP/W can also be used to assess the heterogeneity of the groundwater flow through the saturated materials surrounding and through the CLA.

For this assessment report, SEEP/W particle tracking has been used to observe conservative (not subject to attenuation or retardation) particle migration under advective flow.

This modelling assessment has not been developed in accordance with the 2012 Australian Groundwater Modelling Guidelines (AGWMG). As stated in the Guidelines, they are not intended to prescribe a particular approach to modelling. A detailed Class 3 regional numerical model is currently in development in accordance with the AGWMG for separate purposes. This is a catchment wide (Jan Juc GMA) groundwater model which is being peer reviewed by an Inter-Agency Group (DELWP, SRW, ERR) independent Technical Review Panel. Input parameters used in the catchment wide model have been reviewed and used in this modelling review, e.g., DBF and BF permeability value of $1x10^{-6}$ m/sec. This model also has a typical overall Class 1 model confidence level classification (Merz, 2012), however is considered to be still fit for purpose as it predicts long-term impacts to groundwater and a water body with existing low-quality water (refer to Table 2-1, AGWMG [2012]).

The outcomes from this modelling assessment inform the risk assessment (**Section 10**) and decision-making process by simulating any potential impacts on identified receptors. The modelling may also guide further data acquisition and additional modelling if required.

9.9 Model Construction and Input Parameters

The SEEP/W model was developed sequentially on the basis of the three scenarios described above:

1. Scenario 1 – Initial current condition steady-state model and transient model change in water body elevation from -39.79 mAHD to -17.4 mAHD;
2. Scenario 2 – Transient model, change in water body elevation from -17.4 mAHD to 5.5 mAHD under natural fill conditions; and
3. Scenario 3 – Transient model, change in water body elevation from -17.4 mAHD to 5.5 mAHD under fast fill conditions.

The geometry of the model domain consists of a west to east orientated transect from the water body (in the west) through the fill material and CLA to the edge of the fill material in the east. This orientation is approximate and based on the future steady state radial groundwater flow surrounding the water body, the orientation of the model domain is not considered to have a qualitative or quantitative influence on the model outcomes and assessment of risk to identified environmental values.

The model elevations have been derived from survey data provided by Alcoa. The primary y-axis is defined by the maximum depth of the water body in this section of the model domain, -40 mAHD, and the secondary y-axis by the maximum height of fill material on the eastern wall of the mine pit. The x-axis is the extent of fill material from the base of the water body to the eastern extent of backfilling of overburden. The fill material domain was created as a polygonal region and the CLA plotted as an additional polygon within the fill material region.

The geometry of the overall model domain is shown in **Figure 9-11**.

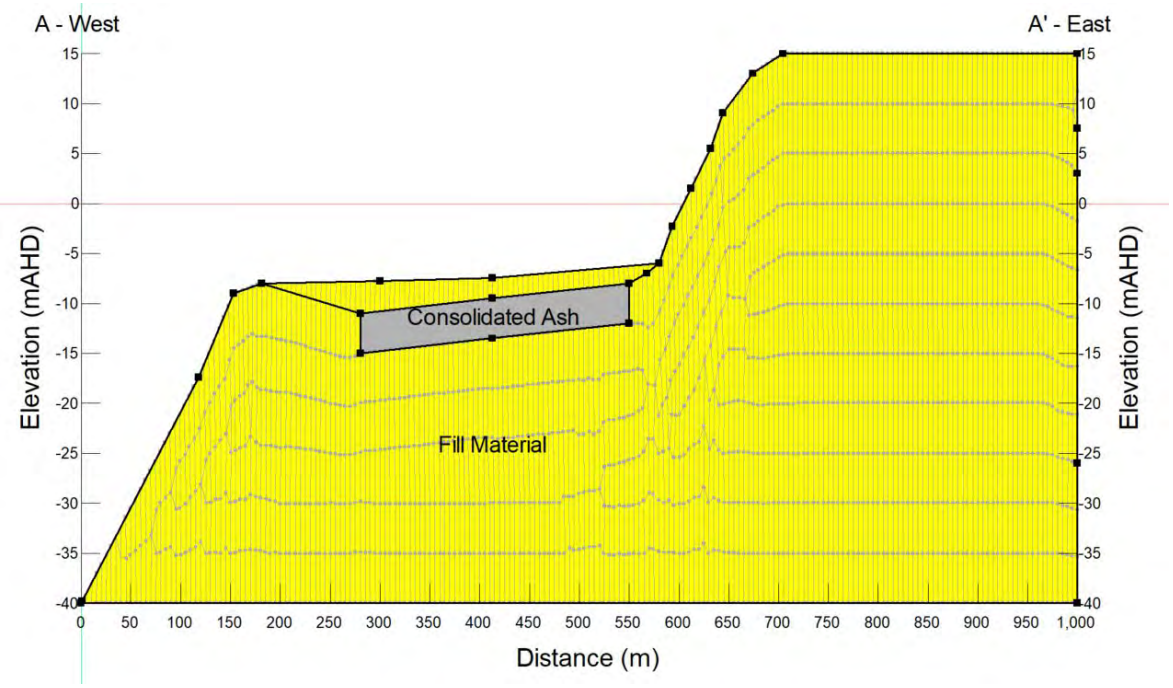

Figure 9-11 Model Domain Geometry

The CLA and clay-rich layer has been conceptualised within SEEP/W as one region. Differentiation of these two materials was not considered necessary when the hydraulic properties of the CLA and clay-rich layer are so similar. The hydraulic conductivity geomean (based on de-ionised water permeameter tests) for the CLA is $1.93x10^{-9}$ m/sec, in comparison to $4.68x10^{-10}$ m/sec for the clay-rich layer (**Table 10** and **Table 14**, attached). Saline permeameter tests conducted on the clay-rich layer indicate a hydraulic conductivity geomean of $1.41x10^{-9}$ m/sec. The CLA hydraulic conductivity has been selected to represent the CLA and clay-rich layer region.

Table 9-3 provides hydraulic conductivities used to represent the CLA and fill material regions. The clay-rich layer is most likely representative of the DBF and upper BF, which are expected to be at the lower range of hydraulic conductivities encountered. The geomean hydraulic conductivity of the clay-rich layer is between $1.41x10^{-9}$ and $4.68x10^{-10}$ m/sec (**Table 10** and **Table 14**, attached) based on the de-ionised and saline permeameter tests; however, due to the limited extent of the clay-rich layer covering the CLA (approximately 1 m thick) and the resolution of the model domain, the clay-rich layer and CLA are represented by one region with a hydraulic conductivity of $2.93x10^{-9}$ m/sec (representative of CLA permeability). The CLA permeability is also very similar to the fill material permeability which surrounds the majority of the ash.

Fill material hydraulic conductivities range between $7x10^{-8}$ and $9x10^{-11}$ m/sec (de-ionised water permeameter tests) and $4x10^{-8}$ and $8x10^{-11}$ m/sec (saline water permeameter tests). These values are representative of vertical hydraulic conductivities, whereas the outcome of the falling head slug test in May 2022 (**Appendix I**) indicates horizontal conductivities are higher, $1.16x10^{-7}$ m/sec. The horizontal hydraulic conductivities used by GHD (2022) in the Anglesea numerical model range between $1.16x10^{-5}$ to $1.16x10^{-7}$ m/sec for the DBF and BF. Based on the reworked nature of the DBF and BF (the fill material) the hydraulic conductivity selected to represent the fill material is $1.16x10^{-6}$ m/sec. The anisotropy between this horizontal conductivity value and the vertical hydraulic conductivity values ranges between 0.1 and 0.0001. A value of 0.005 was used for the Ky/Kz ratio. The application of anisotropy was based on the interpretation of hydraulic field tests.

Four slug tests in the DBF and BF lithology (**Table 9-2** and **Appendix I**) were undertaken (Kx = ranging from $3.1x10^{-6}$ m/sec to $1.1x10^{-7}$ m/sec) and two laboratory permeability tests (representing vertical permeability) with Ky ranging from $2x10^{-9}$ m/sec to $4x10^{-10}$ m/sec). This represents an anisotropy of 1:100 and is quite common in this type of field setting. Furthermore, the calibrated regional numerical model uses a ratio 1:100 with a relatively uniform distribution based on test data, geomean Kv to geomean Kh. A more 'isotropic' distribution may occur within the ash emplacement, but the intent is to examine migration away from CLA area.

Material parameters have been assigned on the basis of the field observations/investigations and laboratory results (**Table 9-3** and **Table 9-4**). The thickness of the CLA and surrounding materials has been sourced from communications from Alcoa. All other CLA parameters provided in **Table 9-3** were sourced from the analysis of site sampling as provided in **Table 10** and **Table 14** (attached). The saturated water content for the CLA region is based on the geomean value of the leached ash assumed porosity results (**Table 10**, attached). The fill material saturated water content is based on the minimum assumed porosity result, as there were not a sufficient number of values to derive a geomean with confidence.

Table 9-3 Material Hydraulic Parameters

Lithological Layer	Volumetric Water Content Function		Hydraulic Conductivity Function		
	Saturated Water Content (fraction)	Sample Material	Estimation Method	Residual Water Content (fraction)	Hydraulic Conductivity (m/sec)
Leached Ash	0.41	Silty Clay	Van Genuchten	0.043	$2.93x10^{-9}$
Fill material	0.41	Sand	Van Genuchten	0.02	$1.16x10^{-6}$

Table Notes:
m/sec = metres per second

Table 9-4 Material Dimension Parameters

Lithological Layer	Dimensions		
	Thickness (m)	Width (m)	Area (m^2)
Leached Ash	4	270	46,000
Fill material	0 to 55	1,000	36,316

Table Notes:
m = metres
m^2 = square metres

The western BC is formed by the mine pit and water body, while the eastern BC represents the transition between the fill material and the natural undisturbed and unconsolidated DBF. The fill material which comprises the majority of the model domain has been compacted and has a higher component of clay. The western and eastern BCs have been developed using existing water body and DBG MB6 elevation datasets. Predicted mine water levels for use in transient Scenarios 2 and 3 were derived from a groundwater model presented in (EHS Support, 2018) along with updated (rehabilitated) mine bathymetry. Forecast groundwater levels in DBG MB6 were conservatively extrapolated based on historical data. These forecasts are shown in **Figure 9-12** and **Figure 9-13**. Refer to the attached **Table 19**, **Table 20**, and **Table 21** (attached) for the measured and extrapolated water levels for the water body (natural and fast fill) and the eastern BC.

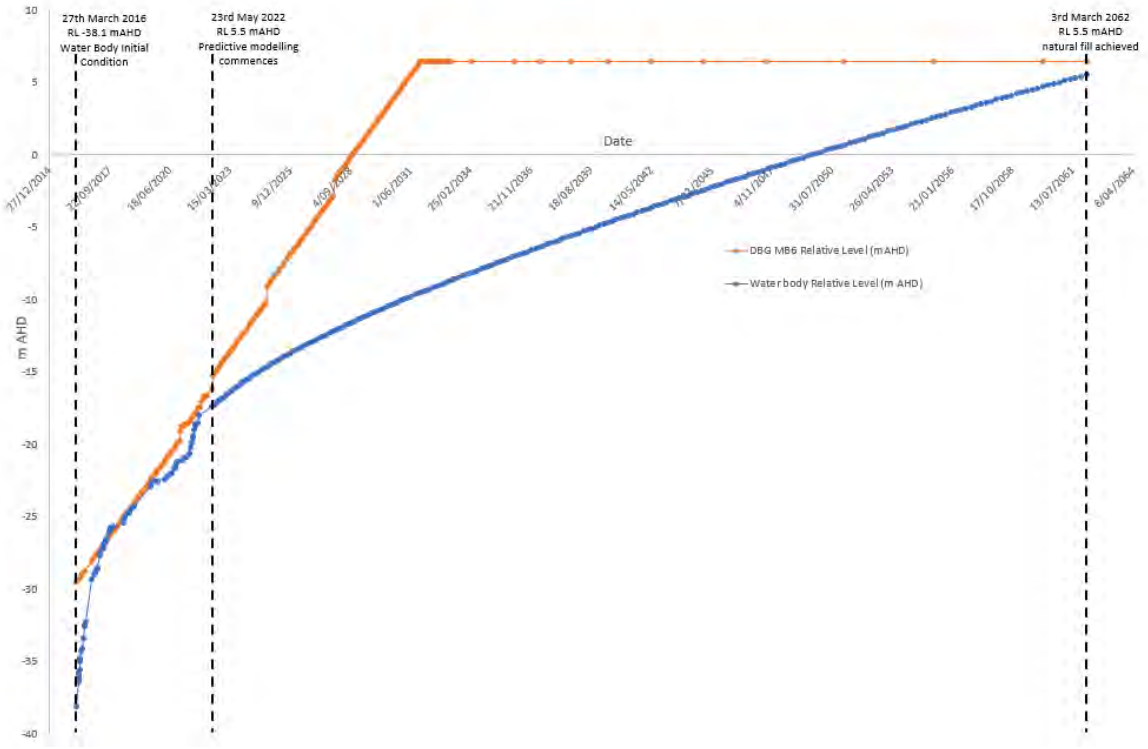

Figure 9-12 Scenario 2 (Natural Fill) Extrapolated Water Body and DBG MB6 Groundwater Recovery

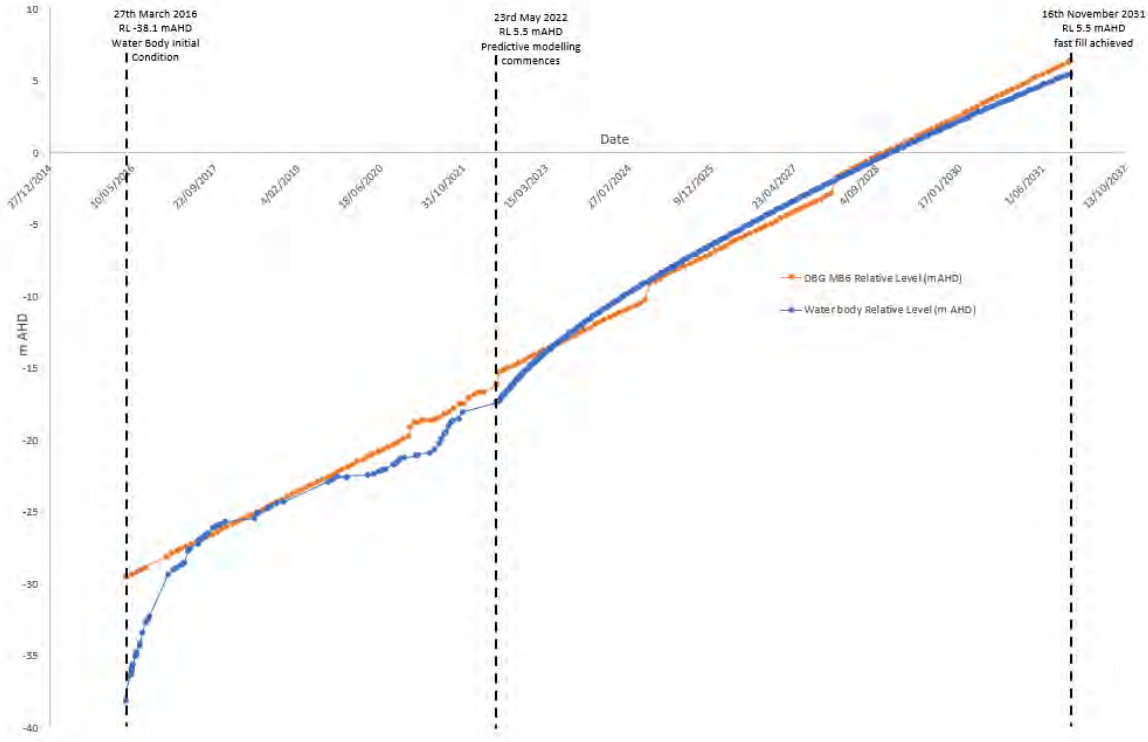

Figure 9-13 Scenario 3 (Fast Fill) Extrapolated Water Body and DBG MB6 Groundwater Recovery

The conceptualisation above and the extrapolated datasets have been used to develop two temporally variable total head BCs, one on the boundary between the water body and the fill material to the west and a second BC between the fill material and the natural DBF to the east of the water body. BC input parameters are provided in **Table 9-5**.

Table 9-5 Boundary Condition Parameters

Boundary Condition	Scenario	Description	Type		Date	Groundwater Flow Direction	Height (mAHD)
Eastern Boundary (SS)	1a	Initial conditions	Total Head	Constant	2016	East to West	-29.51 Assumption
Water Body (SS)	1a	Initial conditions	Total Head	Constant	2016	East to West	-38.10 Site specific data
Eastern Boundary Recovery (T)	1b	Simulation of current conditions	Total Head	Function	2016 to 2022	West to East	-29.51 to -16.55 Site specific data and assumption
Water Body Recovery (T)	1b	Simulation of current conditions	Total Head	Function	2016 to 2022	West to East	-38.10 to -17.4 Site specific data
Eastern Boundary Recovery (T)	2	Simulation of natural fill	Total Head	Function	2016 to 2062	West to East	-29.51 to 6.41 Site specific data and assumption
Water Body Recovery (T)	2	Simulation of natural fill	Total Head	Function	2016 to 2062	West to East	-38.10 to 5.5 Site specific data and assumption
Eastern Boundary Recovery (T)	3	Simulation of fast fill	Total Head	Function	2016 to 2031	Variable	-29.51 to 6.41 Assumption
Water Body Recovery (T)	3	Simulation of fast fill	Total Head	Function	2016 to 2031	Variable	-38.10 to 5.5 Site specific data and assumption

Table Notes:
SS = Steady-State model run
T = Transient model run

The eastern BC marks the separation between the fill material and the undisturbed DBF at the edge of the mine workings. The minimum head for the eastern boundary (SS) condition (Scenario 1a) is set at -29.51 mAHD, which assumes a higher groundwater elevation compared to the water body elevation in March 2016. The difference in elevation creates a hydraulic gradient with westerly groundwater flow towards the water body. The water body BC for Scenario 1a is based on the surveyed elevation in March 2016. This steady-state model sets the initial conditions or parent model which all transient models use as a base model.

The eastern boundary recovery (T) condition (Scenario 1b) is a groundwater level of -29.51 mAHD. This is an extrapolated water level (representative of March 2022) from groundwater elevations reported from DBG MB6 between April 2016 and February 2022 (refer **Table 21**, attached). The water body BC for Scenario 1b is based on the surveyed elevation in March 2022.

The total head BCs for Scenario 2 vary over time and are intended to simulate the future development of the water body under natural fill conditions to an elevation of 5.5 mAHD. The fill rate has been derived from extrapolating the measured water body levels based on estimated inputs from groundwater, rainfall, and surface runoff (**Table 21**, attached). Groundwater flow within the fill material is towards the water body throughout the simulation.

The total head BCs for Scenario 3 also vary over time, however, they simulate the future development of the water body under fast fill conditions to an elevation of 5.5 mAHD. An assumed artificial fill rate of 1.5 gigalitres per year has been used to achieve the 5.5 mAHD water body elevation by 2031 (**Table 20**, attached). During this period the groundwater flow direction fluctuates between a westerly and an easterly direction. This is dependent on the water body and fill material groundwater elevations. **Figure 9-13** illustrates the relationship between water body and fill material groundwater elevations. Between 2023 and 2028 the water body elevation is above the fill material elevation and groundwater flow is easterly away from the water body. From 2028 to 2031 the fill material groundwater elevation is above the water body elevation and groundwater flow changes from an easterly to a westerly direction. The 5.5 mAHD water body elevation is achieved by 2031.

To further support the DBF and BF groundwater elevations under steady state conditions, **Figure 9-14** provides simulated depths to water table within the DBF and BF over time as groundwater levels recover to steady-state conditions. These simulated depths have been derived from the regional numerical model and includes a proposed (not yet approved) UEVF pumping scenario of 1.5 GL/yr for 10 years as well as Barwon Waters Bulk Entitlement Operation for the LEVF; for context, groundwater monitoring well DBG MB6 has a surface elevation of 11.29 mAHD, under steady-state conditions the water table in DBG MB6 has been estimated to be 4.88 m below ground level. This is within the range of water table levels in **Figure 9-14**.

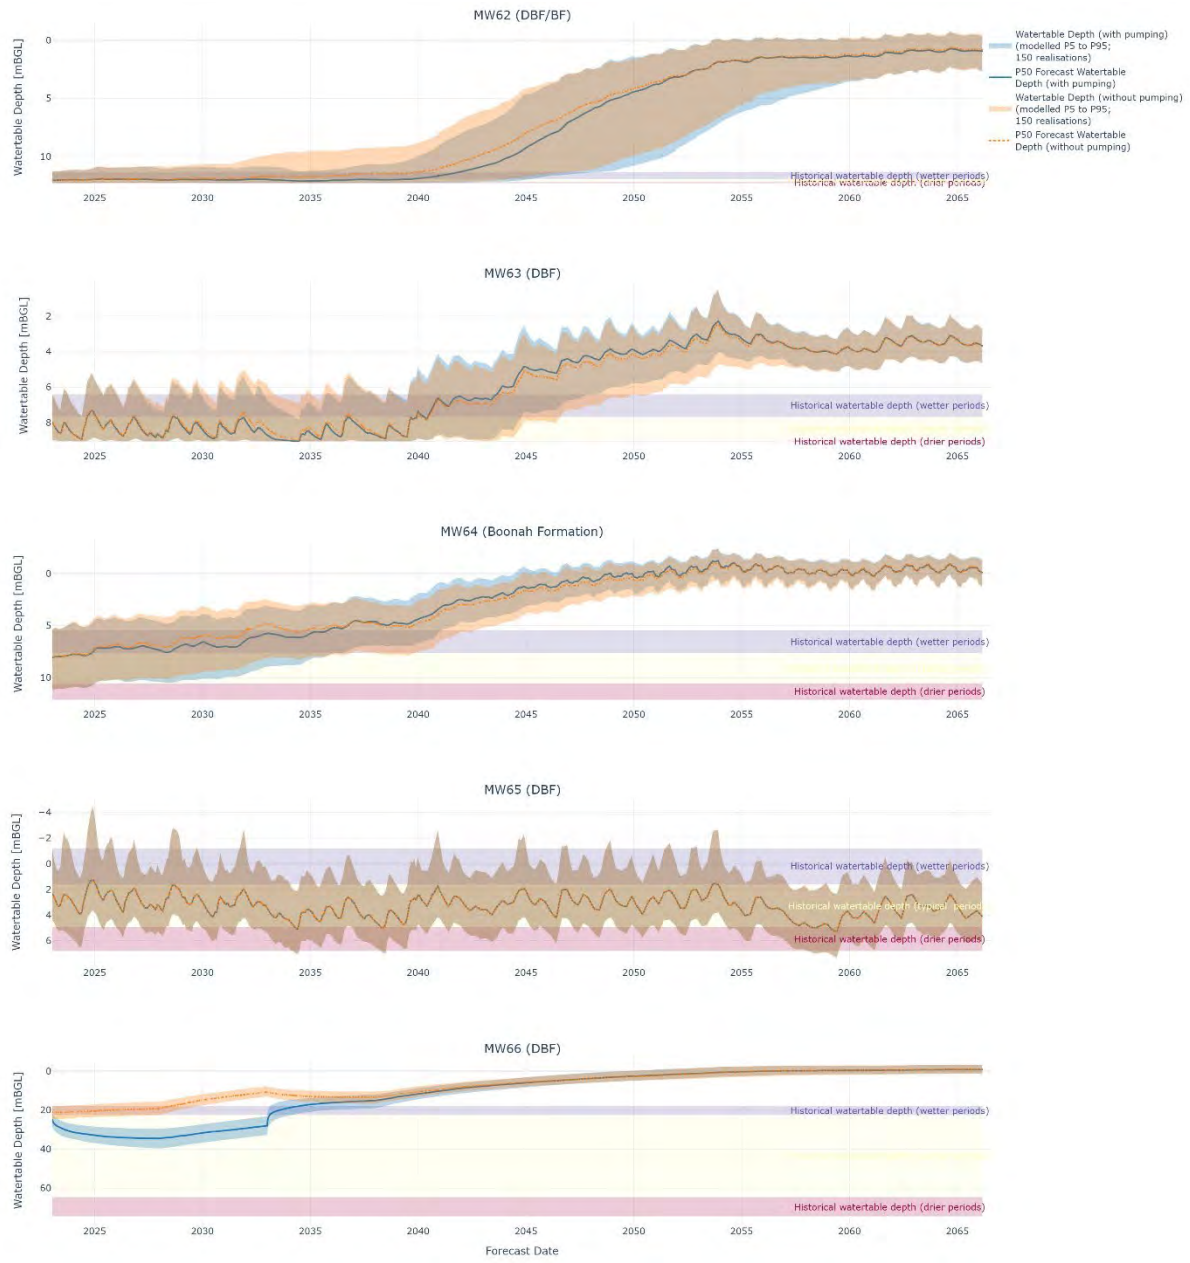

Figure 9-14 DBF and BF Regional Numerical Anglesea Groundwater Model Simulated Depths to Watertable

All of the above input parameters which have been used to characterise the SEEP/W model are within the uncertainty estimate ranges as adopted by the regional numerical model.

A BC has not been specified for rainfall. Whilst rainfall is likely to provide a minor contribution to the water body directly and via surface runoff, evaporation, and evapotranspiration results in a net loss of water. As discussed by EHS Support (2022), the cumulative 5-year period 2005 to 2009 and 2014 to 2018 represent the two driest five-year cumulative rainfall totals on record. Corresponding reductions in catchment flows and infiltration are also expected. The greenmap equation (GHD, 2022) has demonstrated that rainwater infiltration is negated by evaporation and by capillary rise in the vadose zone. Hydrographs of bores screened within the DBF and BF (in the vicinity of the former power station) also show no instantaneous responses to episodic rainfall events (EHS Support, 2022).

Particle tracking has been used to simulate the migration of a conservative solute in groundwater. Particle tracking is provided for Scenario 2 and Scenario 3 and for the sensitivity analysis section.

The model mesh element size has been set as 5 m for both the fill material and the CLA. Quads and triangles were selected for the finite element mesh pattern as this configuration complements the model geometry. A refinement of the CLA element grid was trialled to enable particle tracking on a 1 m scale which relates to the thickness of the clay-rich layer surrounding the CLA; however, the numerical solution did not converge due to the complexity of the finite element mesh in this region and the hydraulic conductivity contrast between the fill material and the CLA.

Model calibration has not been undertaken according to the classical calibration approach where a set of parameters, boundary conditions, and stresses produce simulated heads and fluxes that match field measured values within a pre-defined range of error (Andersen and Woessner, 2002). The classic approach is referred to as the ‘inverse problem’, whereas the ‘forward problem’ has been adopted for this risk assessment, where hydraulic conductivity, specific storage, recharge rate, and initial and final heads are specified, and the model calculates heads and head distribution during the simulation period. The initial conditions are defined from field measured values while the final heads have been verified using the regional numerical model. This approach was adopted because the objective of the modelling was to establish the predicted groundwater flow field in the vicinity of the CLA and assess the level of risk to identified environmental values using the conservative method of particle tracking.

9.10 Results and Discussion

9.10.1 Scenario 1 Current Conditions

The model project definitions for Scenario 1 are provided in **Table 9-6** below.

Table 9-6 Scenario 1 Project Definitions

Scenario 1	Time Frame	Physical Processes	Water	Time	
				Duration (days)	Steps
a. Steady-state	2016	Water	Default parameters	0	-
b. Transient	2016 to 2022	Water	Default parameters	2,248	6

The steady-state model was established for Scenario 1a to derive the initial conditions for the transient model 1b which represent the development of current conditions (March 2022). The initial condition represents the total water heads after the cessation of UEVF dewatering in 2016.

BCs used for the steady-state and transient model runs are as defined in **Table 9-5**.

The result for Scenario 1a (steady-state) is provided as **Figure 9-15**. There is a hydraulic gradient from the east to the west (at the base of the model) as a result of the differing head elevations at the water body and eastern BCs. Groundwater flow is from the east to the water body (west) as controlled by the BCs. Velocity vectors are depicted as arrows (orientated in the direction of flow), with the size of the arrow representing the flow rate. (i.e., larger the arrow, the higher the flow rate).

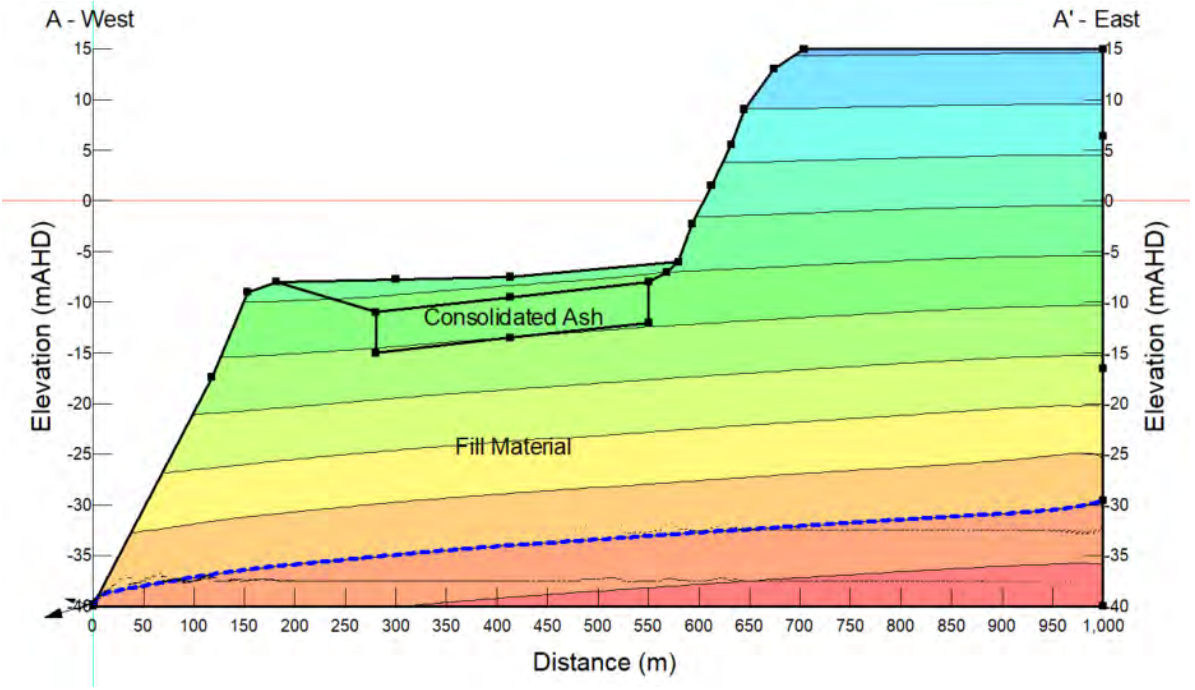

Figure 9-15 Scenario 1a Steady-State Result (2016)

Pore water pressure zones are depicted in the following colour ranges:

- Red - >400 kPa;
- Orange - 200 to 400 kPa;
- Yellow - 0 to 200 kPa;
- Green - 0 to -200 kPa; and
- Blue - >-200 kPa.

The steady-state initial conditions were used as the parent for the transient condition analysis. Transient results for two time-steps are provided in **Figure 9-16** and **Figure 9-17**.

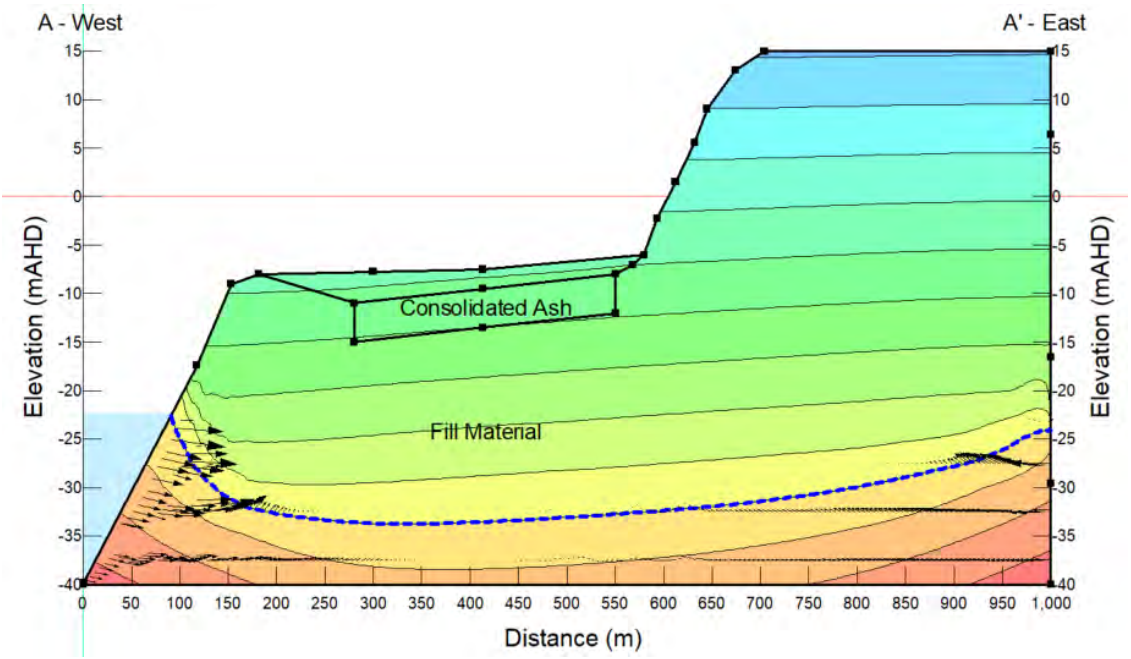

Figure 9-16 Scenario 1b Transient Time-Step 4.1 Years (2020)

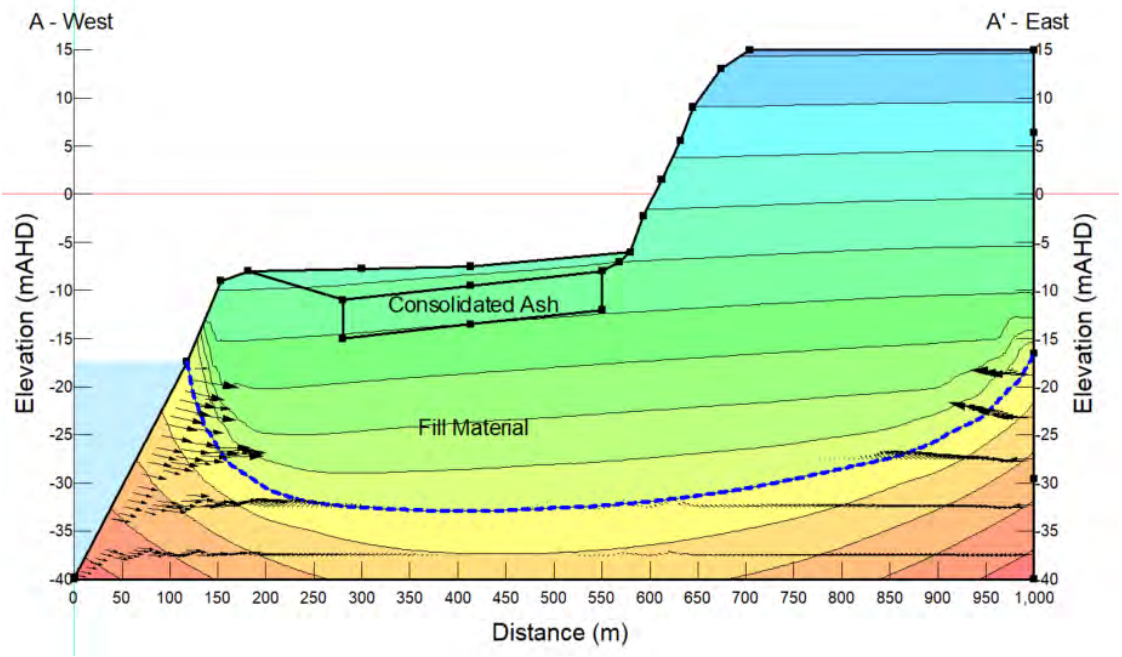

Figure 9-17 Scenario 1b Transient Time-Step 6.15 Years (2022)

The western and eastern hydraulic boundary conditions are providing water into the model domain which has created seepage faces in the fill material. Due to the low hydraulic conductivity of the fill material, the potentiometric surface within the fill is highly variable.

9.10.2 Scenario 2 Natural Fill

The model project definitions for Scenario 2 are provided in **Table 9-7**.

Table 9-7 Scenario 2 Project Definitions

Scenario 2	Time Frame[39]	Physical Processes	Water	Time	
				Duration (days)	Steps
Transient	2016 to 2062	Water	Default parameters	14,529	26

The steady-state model which was established for Scenario 1a was also used to derive the initial conditions for the transient model in Scenario 2. The initial condition represents the total water heads after the cessation of UEVF dewatering in 2016. The Scenario 2 transient model simulates the continuation of increasing water body levels to an elevation of 5.5 mAHD under natural fill conditions. The water body is estimated to reach an elevation of 5.5 mAHD in 2062 (refer to **Figure 9-12**).

BCs used for the transient model runs are as defined in **Table 9-5**.

Transient results for various time steps are provided in **Figure 9-18** through **Figure 9-20.**

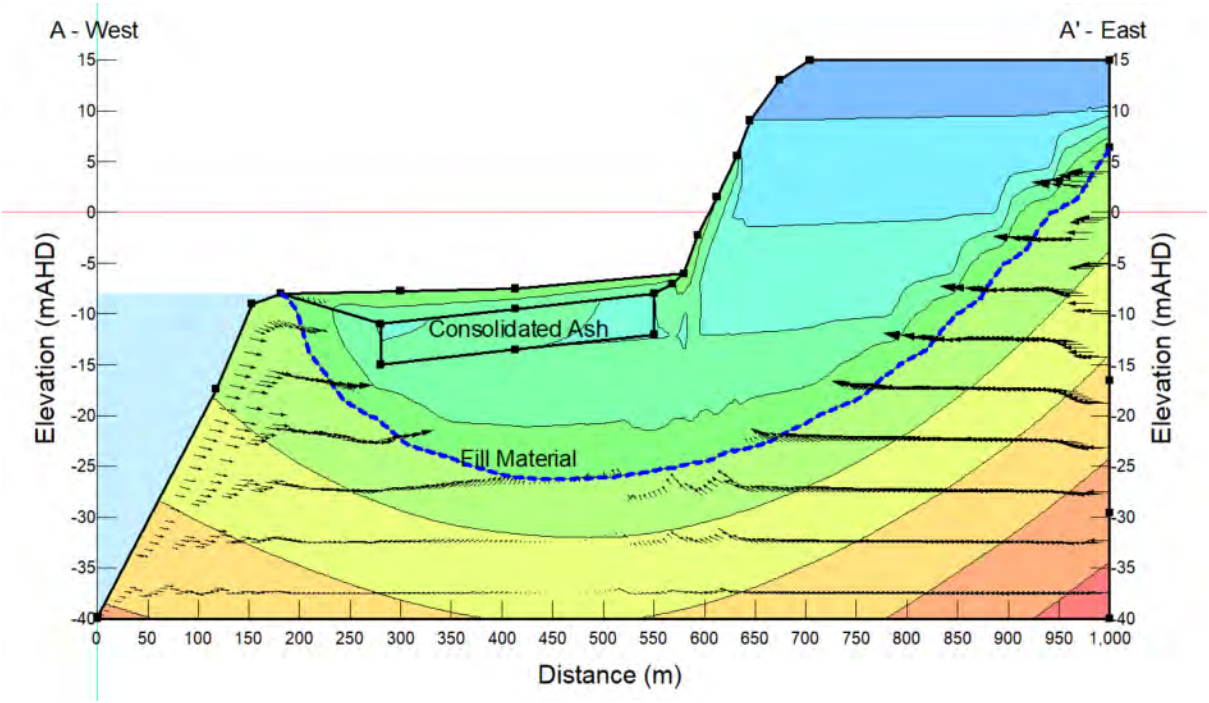

Figure 9-18 Scenario 2 Transient Time-Step 18.4 yrs (2034)

[39] Time Frame is the total time frame as this scenario uses the initial steady-state model (2016) as the parent model.

The simulation time-steps show the contrast in permeability between the CLA and the fill material. **Figure 9-18** and **Figure 9-19** show the lower water pressures (smaller degree of saturation) within the CLA in comparison to the fill material. The CLA is still not saturated by 2039 (**Figure 9-18**) as indicated by the water table and more negative pore water pressures (blue zone surrounded by green zone).

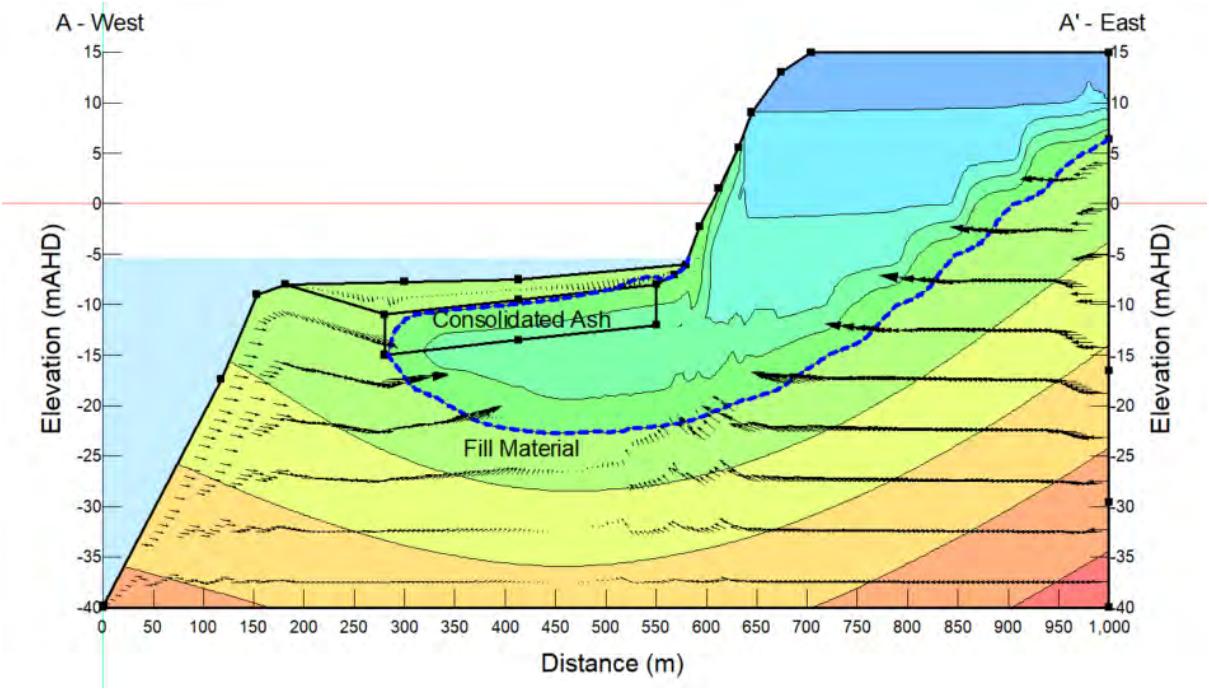

Figure 9-19 Scenario 2 Transient Time-Step 22.9 yrs (2039)

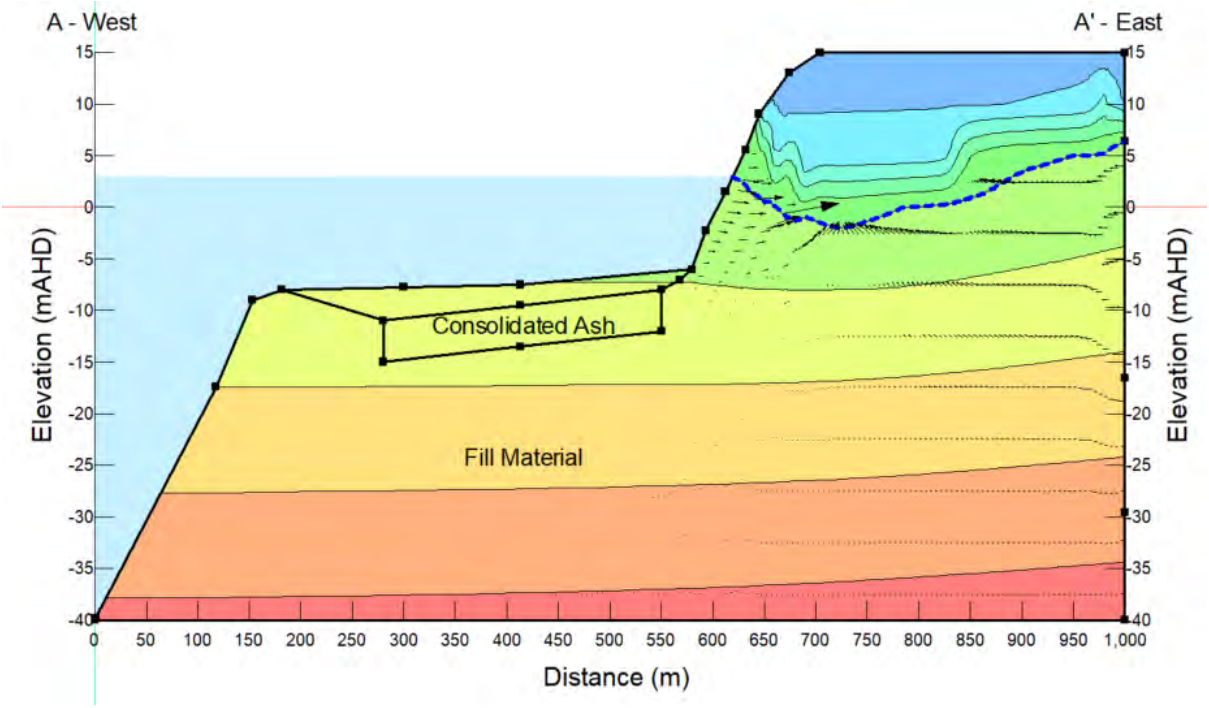

Figure 9-20 Scenario 2 Transient Time-Step 39.8 yrs (2062)

The 'depression' in the water table surface at final time-step 39.8 years (**Figure 9-20**), indicates that steady-state conditions were not achieved for this transient simulation. The low permeability of the fill material controls the slow seepage and saturation of the fill material over time.

The time-step representative of the water body at an elevation of 5.5 mAHD was simulated as a steady-state model (**Figure 9-21**). Contours and mesh (elements and nodes) have been switched off in this figure to show the flow Paths (green lines) more clearly.

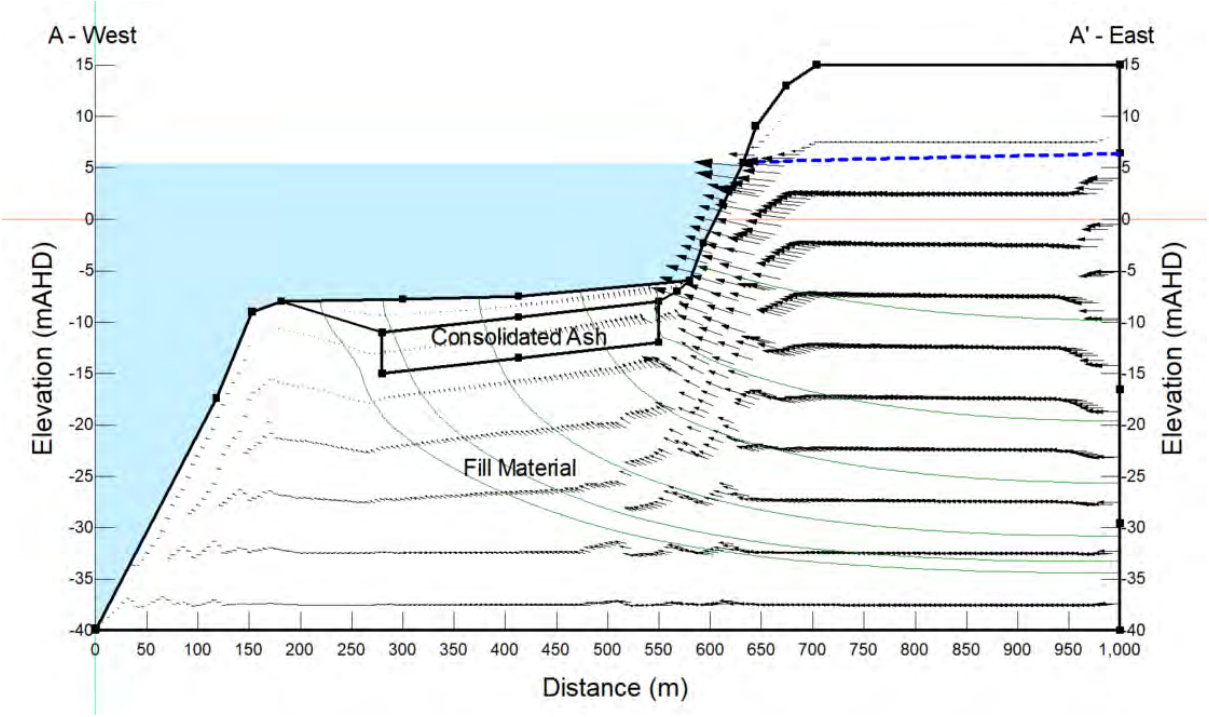

Figure 9-21 Scenario 2 Steady-State Westerly Groundwater Flow – Flow Paths

Flow paths are shown in the vicinity of the CLA (drawing flow paths is not possible in a transient analysis). Flow paths in SEEP/W are not flow lines as in a traditional flow net. Flow paths are a line based on velocity vectors within an element and draw the paths that a drop of water would follow under steady-state conditions from the point of entrance into the flow regime to the point of exit. Flow paths can be used to provide a conservative estimate of the transport direction of a particle in groundwater. There is a slight deflection of the flow paths in the vicinity of the CLA which is due to the hydraulic conductivity contrast between the CLA and the fill material. Although the particles are not predicted to migrate to the water body during the specified time frames, it is noted that the flow paths in **Figure 9-21** do indicate that ultimately there is potential for particle discharge into the water body.

9.10.2.1 Particle Tracking

Particle tracking has been used to view single particle flow paths within the transient simulations. The particle flow paths are not the same as the flow paths computed in steady-state simulations, as these paths are known through the entire model domain as the flow is established. With transient particle flow paths, a particle has infinite vectors to flow over time and particle pathways are unknown until the simulations have completed.

Particles have been placed within the CLA region at a time-step where the CLA is saturated. Simulations did not converge when particles were placed in unsaturated parts of this region. This is likely to have been a function of the low hydraulic conductivity and negative pore water pressures.

Six particles were placed within the CLA region within 1 m of the boundary. This distance is representative of the clay-rich layer surrounding the CLA (**Figure 9-22**).

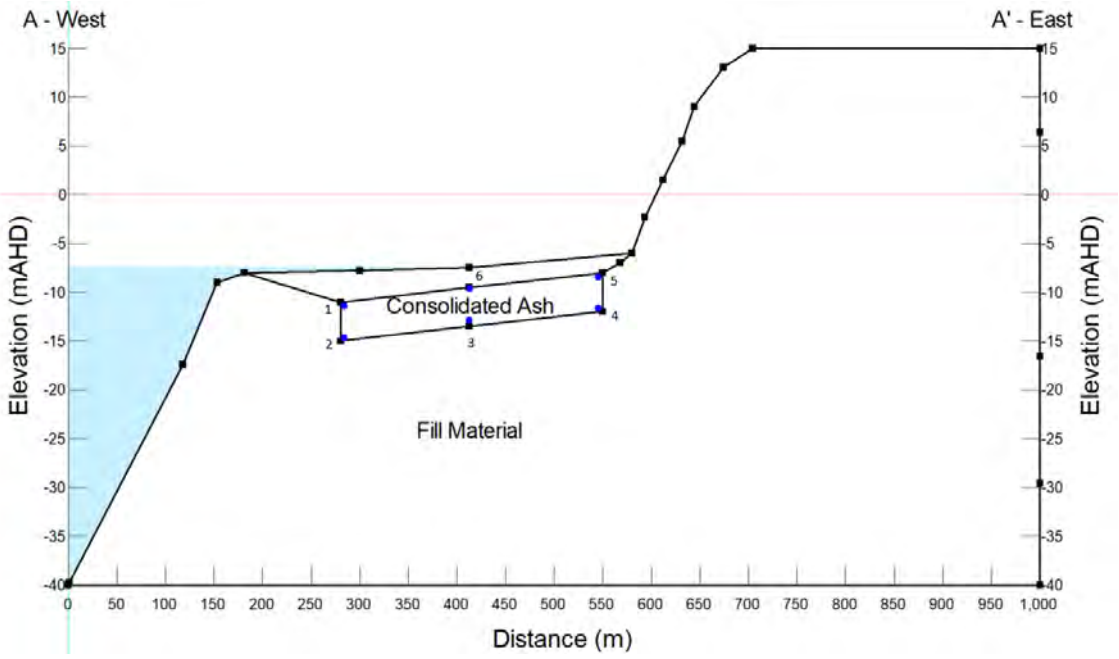

Figure 9-22 Scenario 2 Particle Tracking Initial Conditions – Particle Locations

The time-step selected for particle placement is 30.6 years and approximately represents 2047, at which point the leached ash is simulated to be saturated.

The particle tracking simulation was run for a total of 100 years within a 131-year total simulation period. This represents a total time frame 2016 through to 2147. The groundwater flow direction is westerly throughout the simulation (**Figure 9-23**).

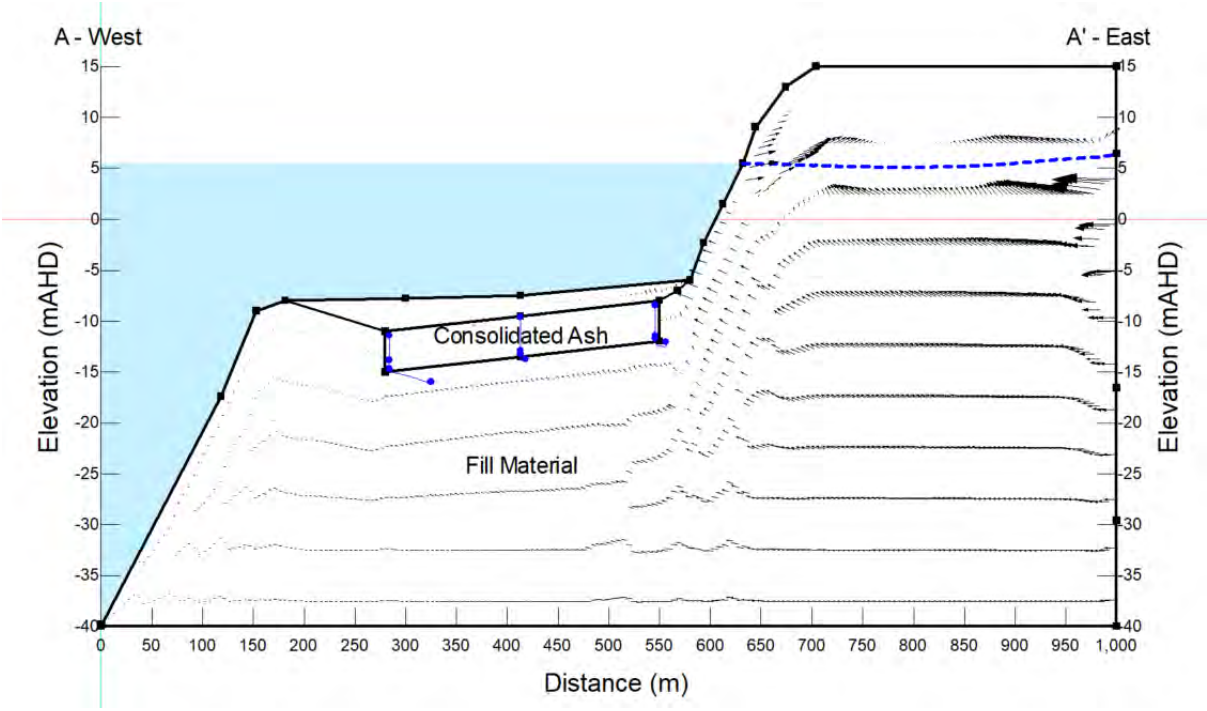

Figure 9-23 Scenario 2 Particle Tracking 2047 to 2147 Simulation – 100 Year Time Frame

Table 9-8 provides tracking information on each particle within the CLA and fill material domains.

Table 9-8 Particle Tracking 100-Year Time Frame

Particle		1	2	3	4	5	6
Travel Time (days)		36,500	36,500	36,500	36,500	36,500	36,500
Initial Location	**X-Coordinate (m)**	284	284	413	546	546	413
	Y-Coordinate (m)	-11	-15	-13	-12	-8	-10
Final Location	**X-Coordinate (m)**	284	325	418	556	546	413
	Y-Coordinate (m)	-14	-16	-14	-12	-11	-13
Total Distance Travelled (m)		3	46	10	13	4	4
Average Speed (m/d)		$7.x10^{-5}$	$1x10^{-3}$	$3x10^{-4}$	$4x10^{-4}$	$1x10^{-4}$	$1x10^{-4}$

Particle 2 is observed to have travelled approximately 46 m; however, the particle pathway is not linear along the x axis, and overall it has travelled 41 m in an easterly direction but at a tangent before reversing direction as flow with the model domain evolves (**Figure 9-24**).

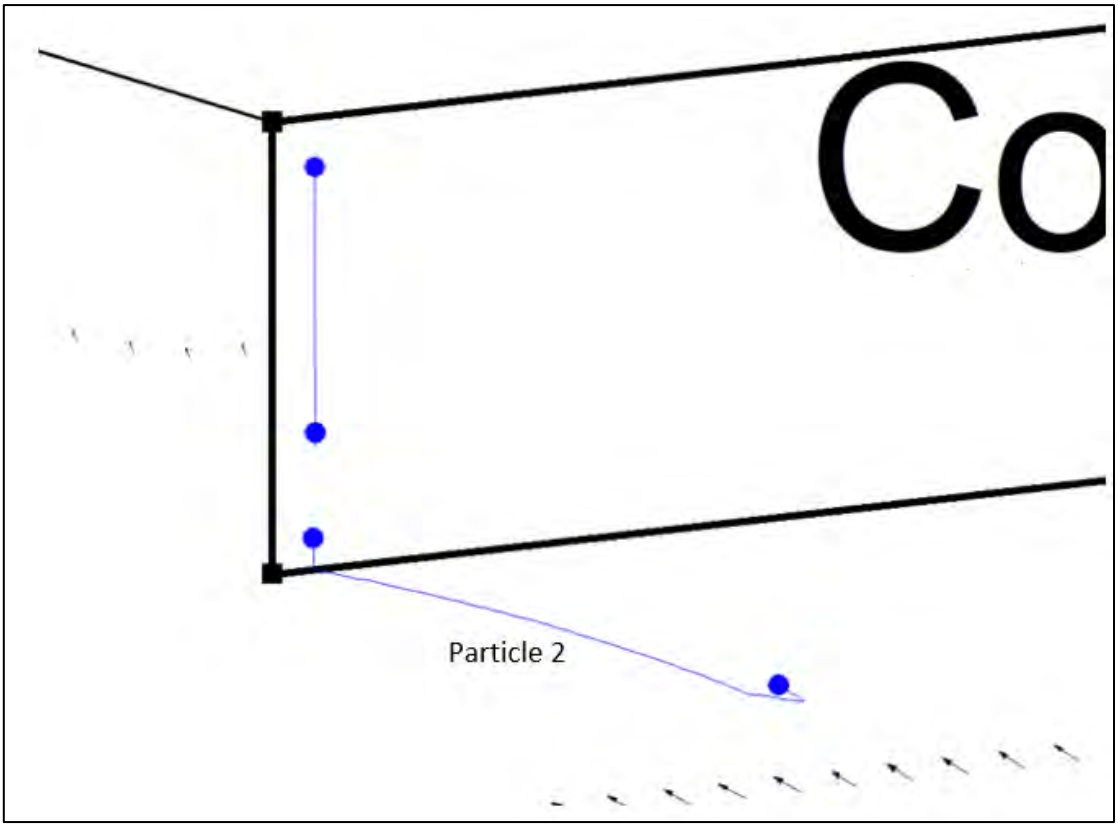

Figure 9-24 Scenario 2 Particles 1 and 2 Travel Pathways at 2147 yr Time-step

Particle tracking was extended for another 100 years to 2247 (**Figure 9-25**). The particles are observed to have migrated a minimal distance with no discharge to the water body after 200 years.

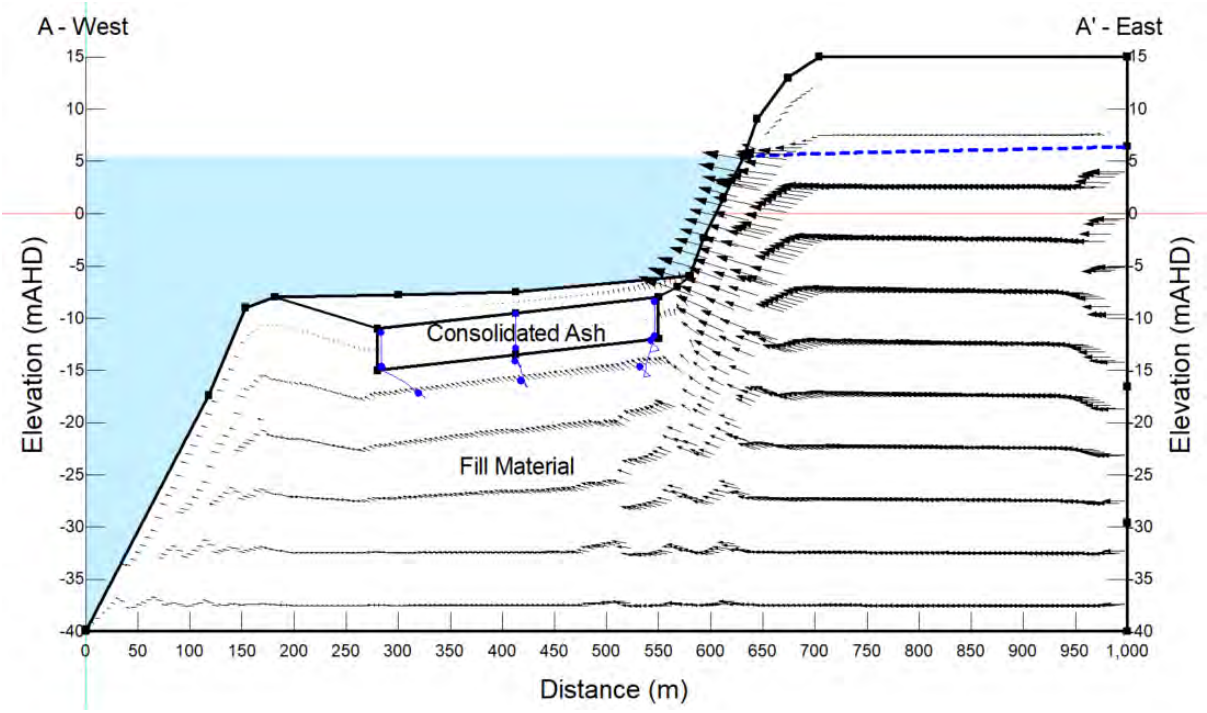

Figure 9-25 Scenario 2 Particle Tracking 2047 to 2247 Simulation – 200 Year Time Frame

9.10.3 Scenario 3 Fast Fill

The model project definitions for Scenario 3 are provided in **Table 9-9**.

Table 9-9 Scenario 3 Project Definitions

Scenario 3	Time Frame	Physical Processes	Water	Time	
				Duration (days)	Steps
Transient	2016 to 2031	Water	Default parameters	5,713	10

The steady-state model which was established for Scenario 1a was also used to derive the initial conditions for the transient model in Scenario 3. The initial condition represents the total water heads after the cessation of UEVF dewatering in 2016. The Scenario 3 transient model simulates the continuation of increasing water body levels to an elevation of 5.5 mAHD under fast fill conditions (addition of 1.5GL/yr). The water body is estimated to reach an elevation of 5.5 mAHD in 2031 (**Figure 9-13**). The simulation has been extended by two years until 2033 so the fill material groundwater elevation recovers to a height above the water body elevation (6.42 mAHD) which establishes the predicted westerly groundwater flow direction.

BCs used for the transient model runs are as defined in **Table 9-5**.

Transient results for various time steps are provided in **Figure 9-26** through **Figure 9-28**.

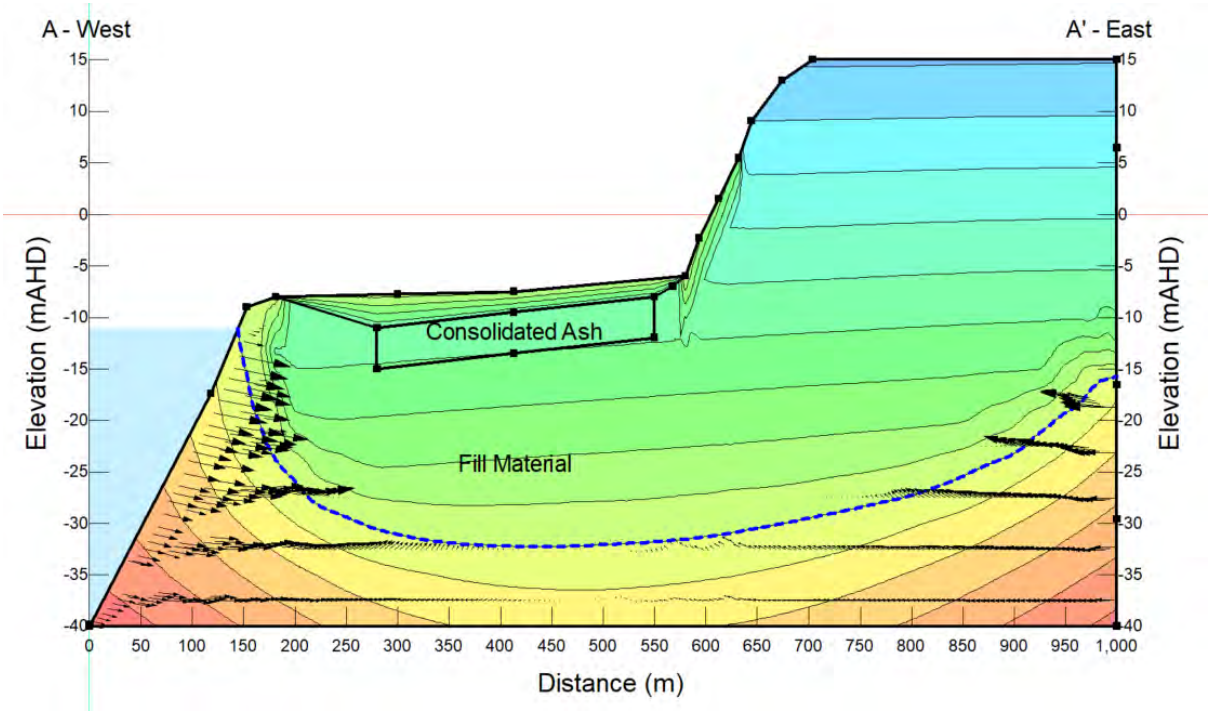

Figure 9-26 Scenario 3 Transient Time-Step 7.85 Years (2024)

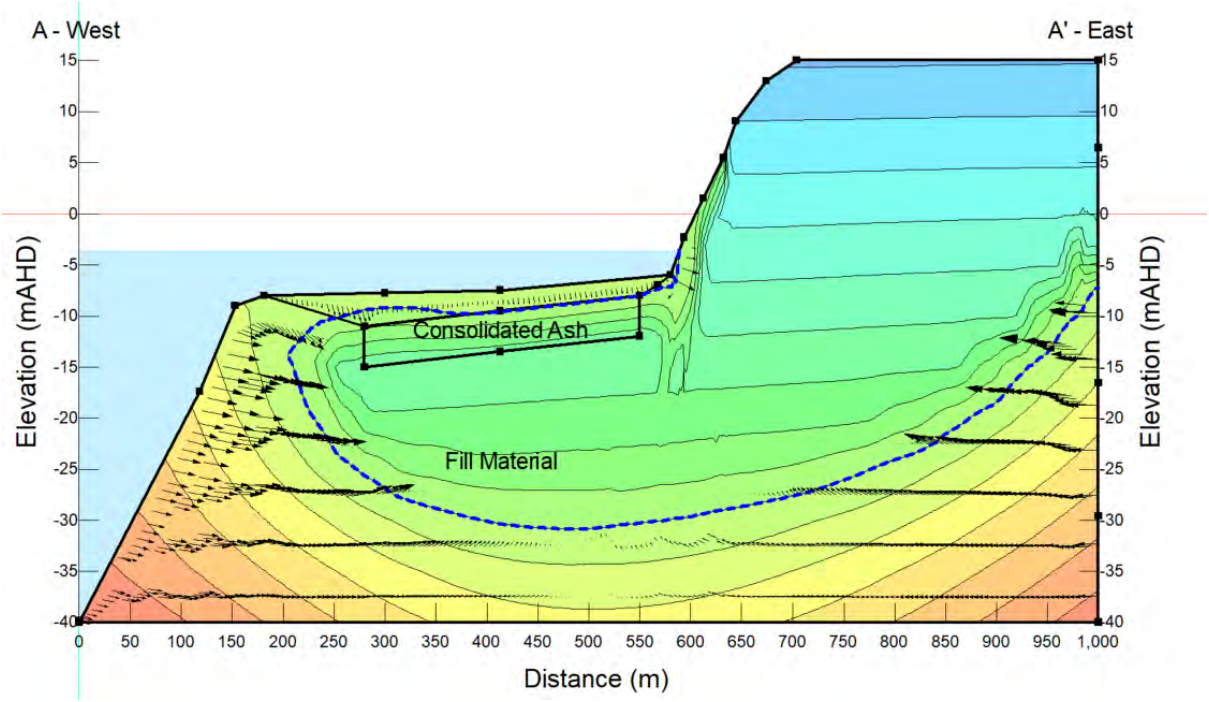

Figure 9-27 Scenario 3 Transient Time-Step 11 Years (2027)

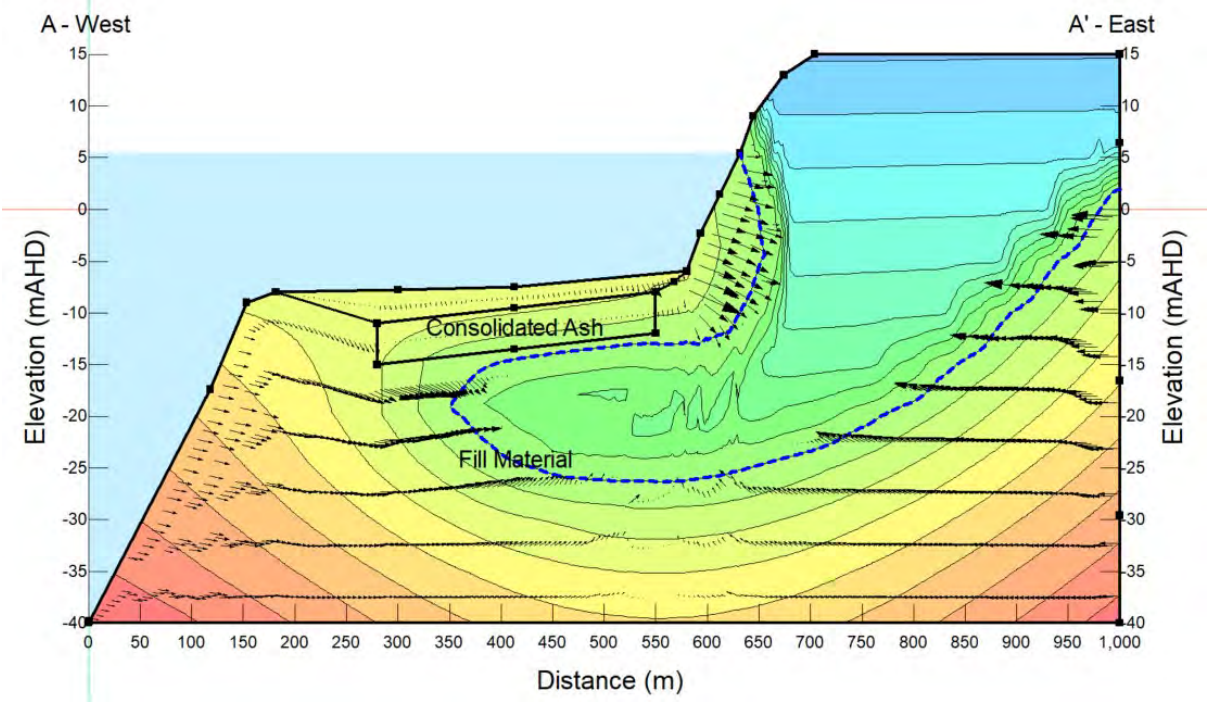

Figure 9-28 Scenario 3 Transient Time-Step 15.7 Years (2031)

The depression in the water table surface in **Figure 9-28** indicates steady-state conditions have not been achieved. Similar to Scenario 2, the low permeability of the fill material is controlling the slow saturation; however, for the fast fill scenario this is more evident in the recovering water table surface.

9.10.3.1 Particle Tracking

Particle tracking has been used to view single particle flow paths within the transient simulations. The particle flow paths are not the same as the flow paths computed in steady-state simulations, as these paths are known through the entire model domain as the flow is established. With transient particle flow paths, a particle has infinite vectors to flow over time and it is not known what the particle path will be until the simulations have completed.

Six particles were placed within the CLA region within 1 m of the boundary. This distance is representative of the clay-rich layer surrounding the CLA (**Figure 9-29**).

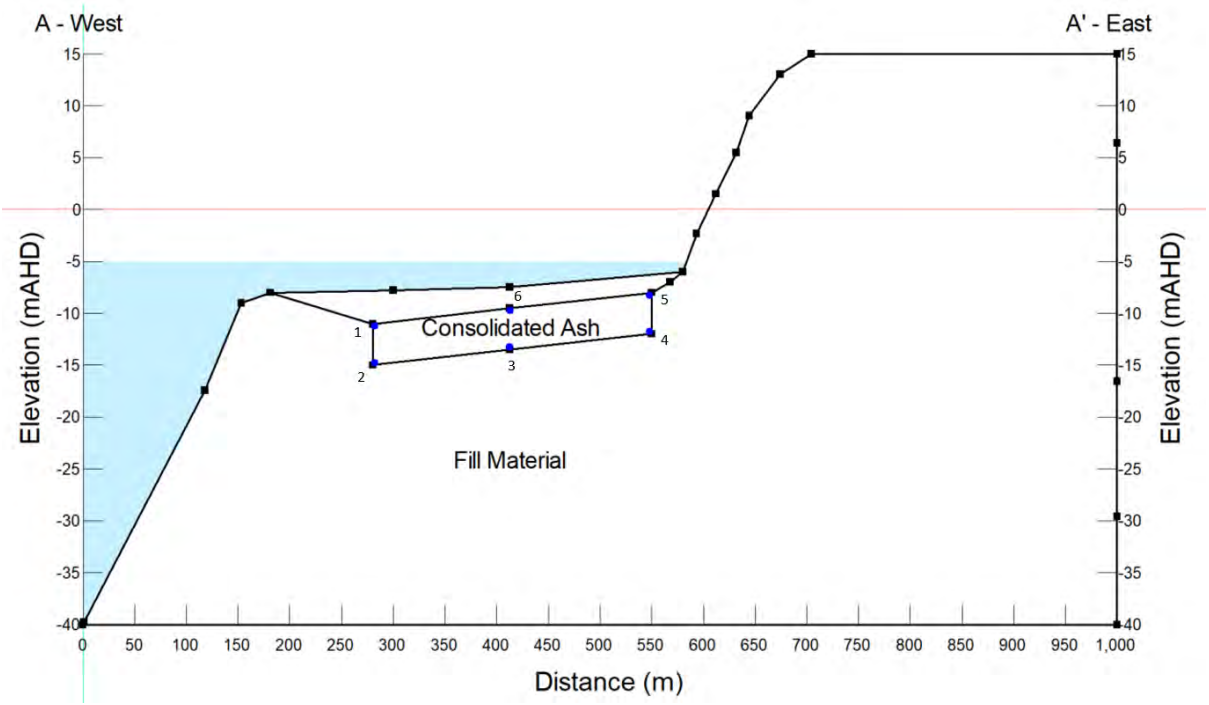

Figure 9-29 Scenario 3 Particle Tracking Initial Conditions – Particle Locations

The time-step selected for particle placement is 14.1 years and represents 2030, at which point the CLA is predicted to be saturated.

The particle tracking simulation was run for a total of 100 years within a 114-year total simulation period. This represents a total time frame 2016 through to 2127. The groundwater flow direction is westerly and discharges to the water body (**Figure 9-30**).

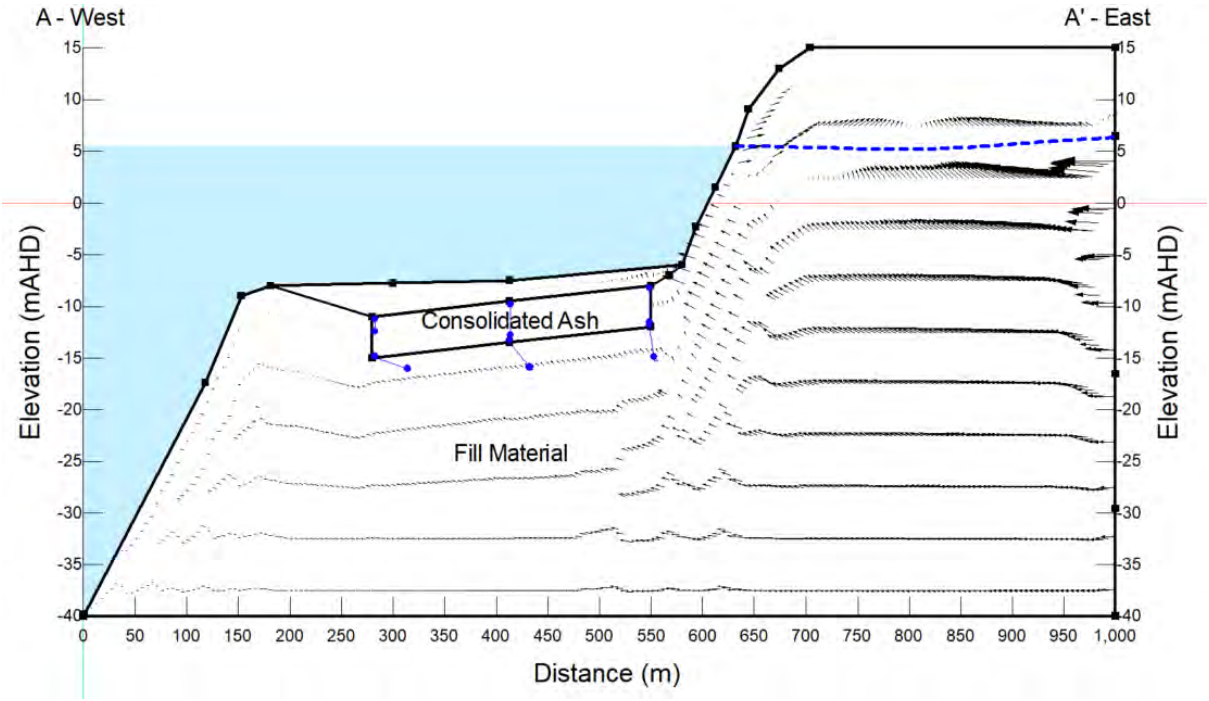

Figure 9-30 Scenario 3 Particle Tracking 2030 to 2130 Simulation – 100 Year Time Frame

Table 9-10 below provides tracking information on each particle within the CLA and fill material domains.

Table 9-10 Particle Tracking 100-Year Time Frame

Particle		1	2	3	4	5	6
Travel Time (days)		36,500	36,500	36,500	36,500	36,500	36,500
Initial Location	X-Coordinate (m)	282	282	413	548	548	413
	Y-Coordinate (m)	-11	-15	-13	-12	-8	-10
Final Location	X-Coordinate (m)	282	314	432	553	548	413
	Y-Coordinate (m)	-13	-16	-16	-15	-12	-13
Total Distance Travelled (m)		1	38	26	13	4	4
Average Speed (m/d)		$4x10^{-5}$	$1x10^{-3}$	$7x10^{-4}$	$4x10^{-4}$	$1x10^{-4}$	$1x10^{-4}$

Particle 2 is observed to have travelled approximately 38 m, however the particle pathway is not linear along the x-axis; overall, it has travelled 31 m in an easterly direction but at a tangent before reversing direction to the west as groundwater flow with the model domain evolves (**Figure 9-31**).

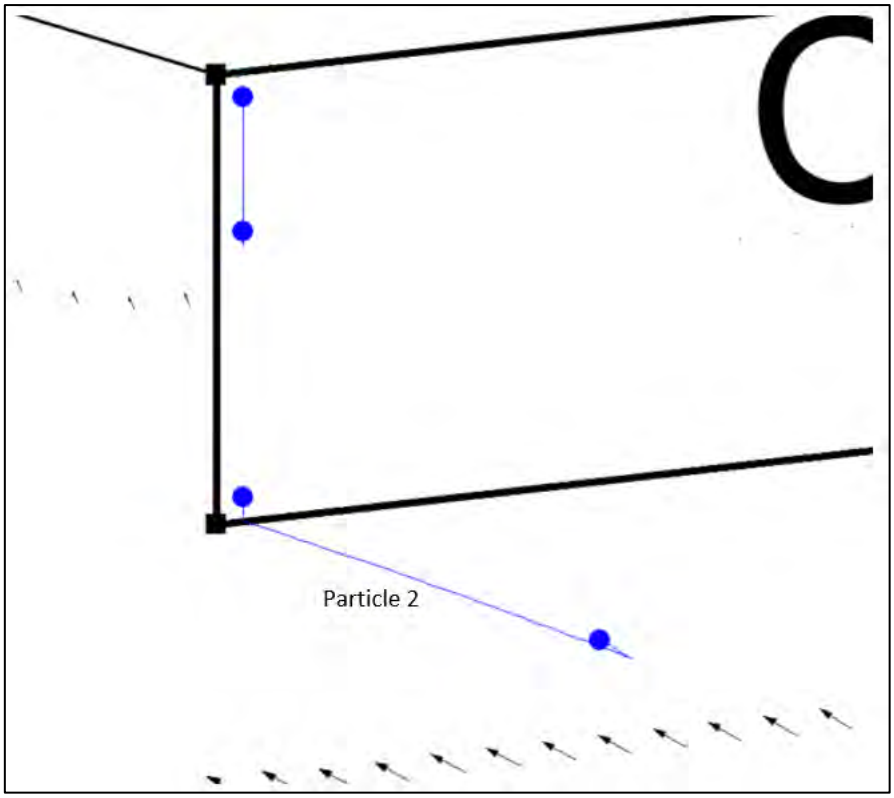

Figure 9-31 Scenario 3 Particles 1 and 2 Travel Pathways at 2130 yr Time-step

Particle tracking was extended for another 100 years to 2230 (**Figure 9-32**). The particles are observed to have migrated a minimal distance (3 m) with no discharge to the water body after 200 years.

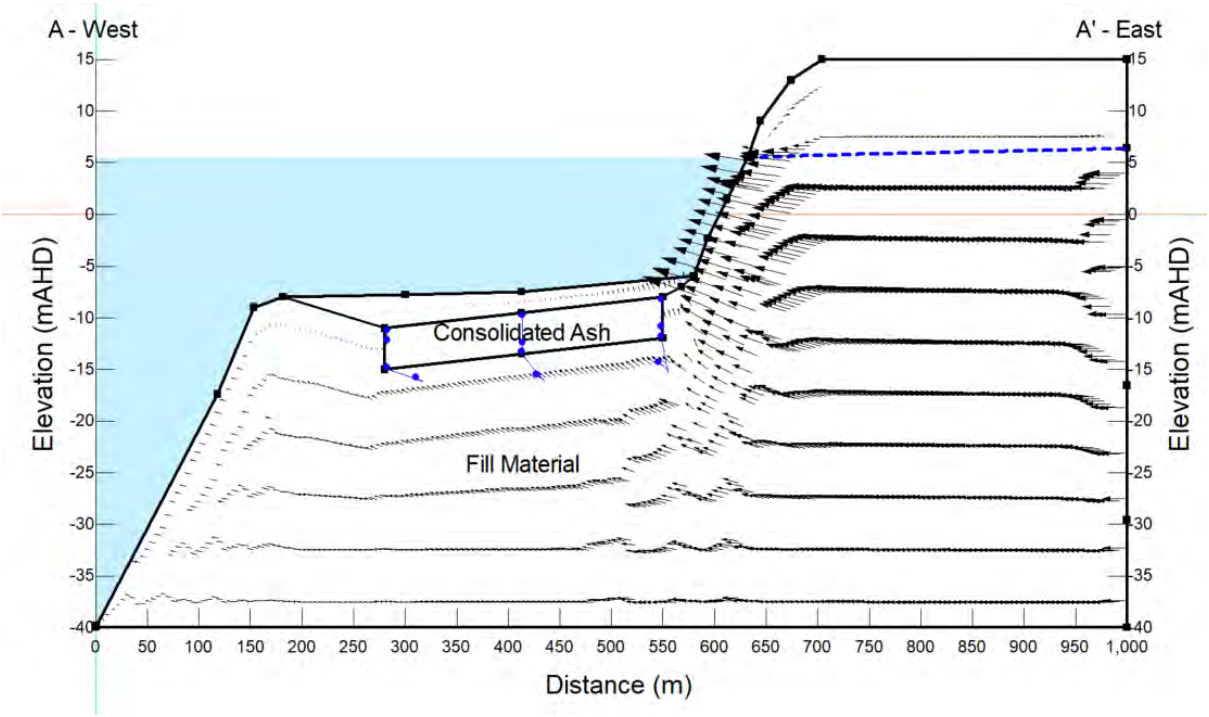

Figure 9-32 Scenario 3 Particle Tracking 2030 to 2230 Simulation – 200 Year Time Frame

Although the particles are not predicted to migrate to the water body during the specified time frames, it is noted that flow paths (**Figure 9-21**) do indicate that ultimately there is potential for particle discharge into the water body.

9.10.4Sensitivity Analysis

The hydraulic conductivity of the materials and the fill rate were selected as parameters for sensitivity analysis.

The hydraulic conductivity of the CLA was increased by three orders of magnitude, from $2.9x10^{-9}$ m/sec to $2.9x10^{-6}$ m/sec. Sensitivity analysis was conducted for both Scenarios 2 and 3. Particle tracking was also enabled for both scenarios. Scenario 2 particle tracking was conducted for 100 years in a total transient simulation of 131 years. Scenario 3 particle tracking was conducted for 100 years in a total transient simulation of 114 years (**Section 9.10.4.1** and **Section 9.10.4.2**).

A fill rate was used to depict an event where the water body fills after a storm event and prolonged heavy rainfall. This has been simulated as a 15 GL volume of water added in 12 months (2023) at a single time step. The simulation was extended for an additional 50 years until 2073 to observe changes in the model domain flow regime (**Section 9.10.4.3**).

9.10.4.1 Scenario 2 Hydraulic Conductivity

Scenario 2 was re-simulated using an increased hydraulic conductivity for the CLA of $2.9x10^{-6}$ m/sec.

The time-step representative of the water body at an elevation of 5.5 mAHD was simulated as a steady-state model (**Figure 9-33**). Contours and mesh (elements and nodes) have been switched off in this figure to show the flow Paths (green lines) more clearly. The comparison of **Figure 9-21** with **Figure 9-33** indicates the higher permeability of the CLA is not having a significant effect on the flow pathways which is expected as the fill material and CLA hydraulic permeabilities are very similar.

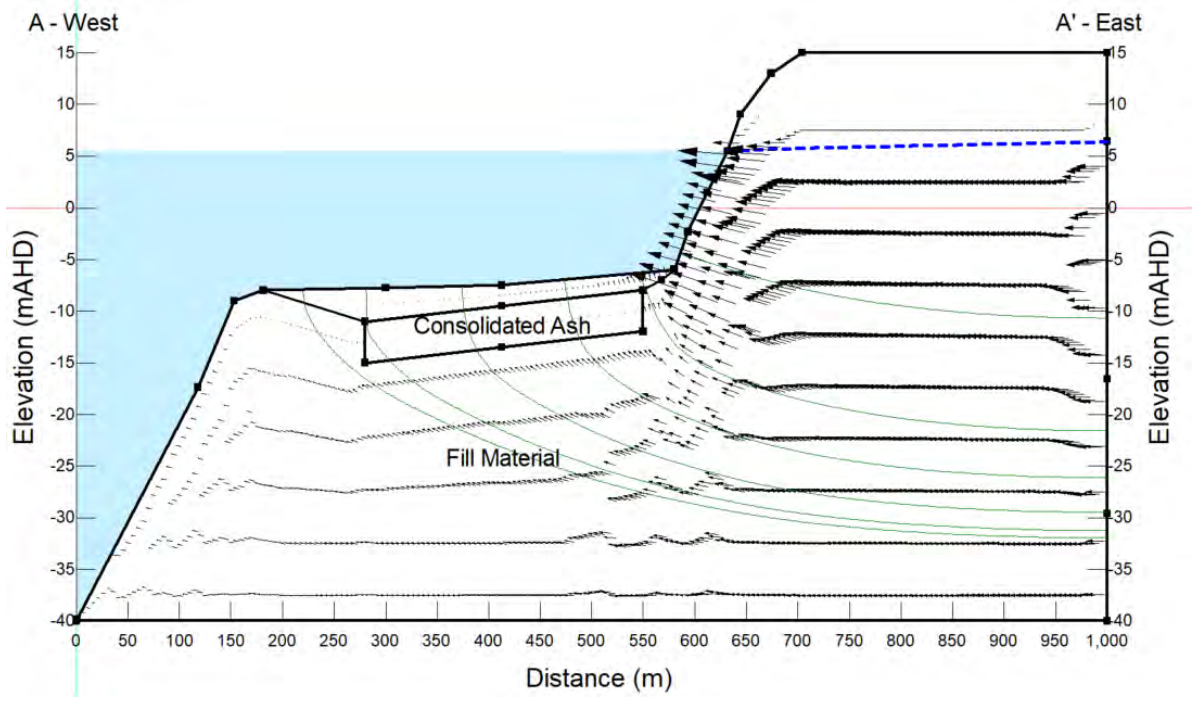

Figure 9-33 Scenario 2 Steady-State Westerly Groundwater Flow, Ash Hydraulic Conductivity $2.9x10^{-6}$ m/sec – Flow Paths

Particle tracking was conducted for 100 years in a total transient simulation of 131 years (**Figure 9-34**). Particle locations are the same as those provided in **Figure 9-22**.

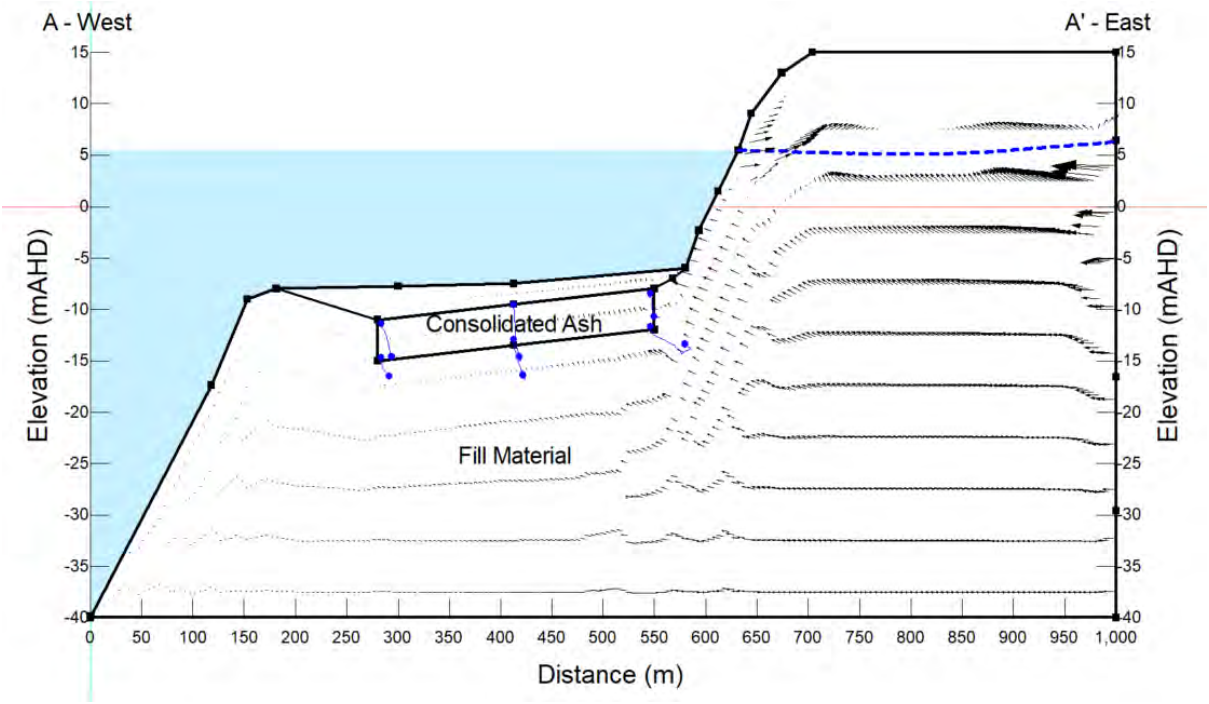

Figure 9-34 Particle Tracking 2047 to 2147 Simulation – Scenario 2 Sensitivity Analysis

Table 9-11 provides tracking information on each particle within the CLA and fill material domains. Scenario 2 particle tracking was conducted for 100 years in a total transient simulation of 131 years.

Table 9-11 Particle Tracking – Scenario 2 Sensitivity Analysis

Particle		1	2	3	4	5	6
Travel Time (days)		36,500	36,500	36,500	36,500	36,500	36,500
Initial Location	X-Coordinate (m)	284	284	413	546	546	413
	Y-Coordinate (m)	-11	-15	-8	-12	-8	-10
Final Location	X-Coordinate (m)	293	291	422	580	550	418
	Y-Coordinate (m)	--15	--17	-16	-13	-11	-15
Total Distance Travelled (m)		12	11	14	46	24	11
Average Speed (m/d)		$3x10^{-4}$	$3x10^{-4}$	$4x10^{-4}$	$1x10^{-3}$	$7x10^{-4}$	$3x10^{-4}$

Particle 4 is observed to have travelled approximately 46 m, however the particle pathway is not linear along the x axis; overall, it has travelled 34 m in an easterly direction but at a tangent before reversing direction as groundwater flow with the model domain evolves (**Figure 9-35**).

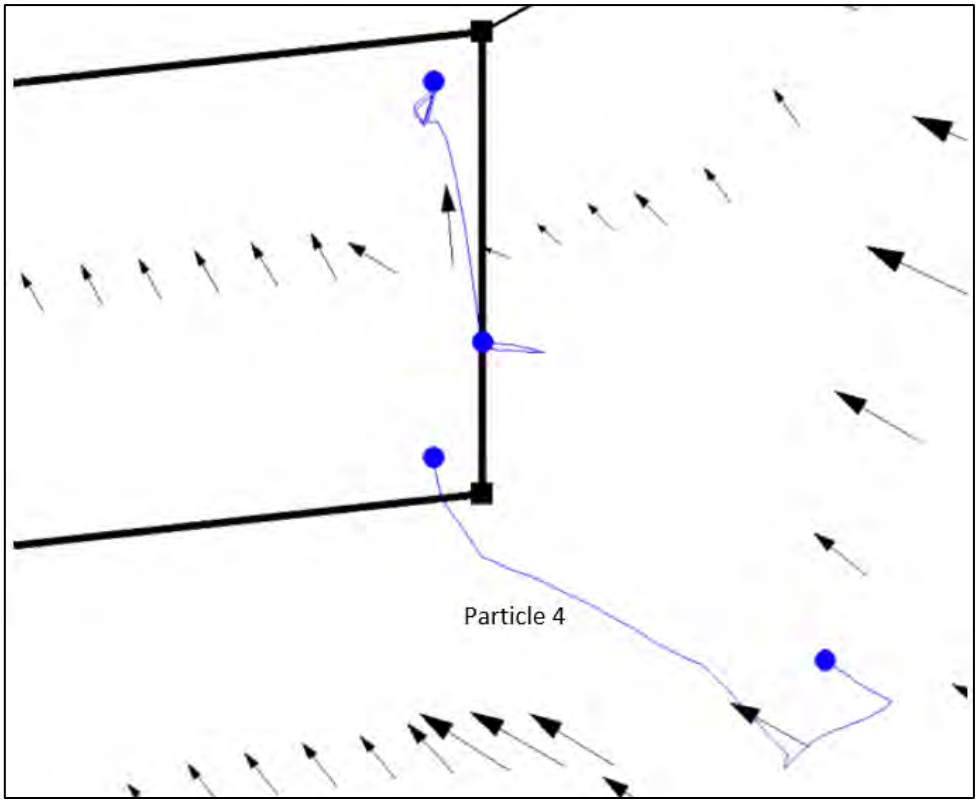

Figure 9-35 Particles 4 and 5 Travel Pathways at 2147 yr Time-step

9.10.4.2 Scenario 3 Hydraulic Conductivity

Scenario 3 was re-simulated using an increased hydraulic conductivity for the CLA of 2.9×10^{-6} m/sec.

Particle tracking was conducted for 100 years in a total transient simulation of 114 years (**Figure 9-36**). Particle locations are the same as those provided in **Figure 9-22**.

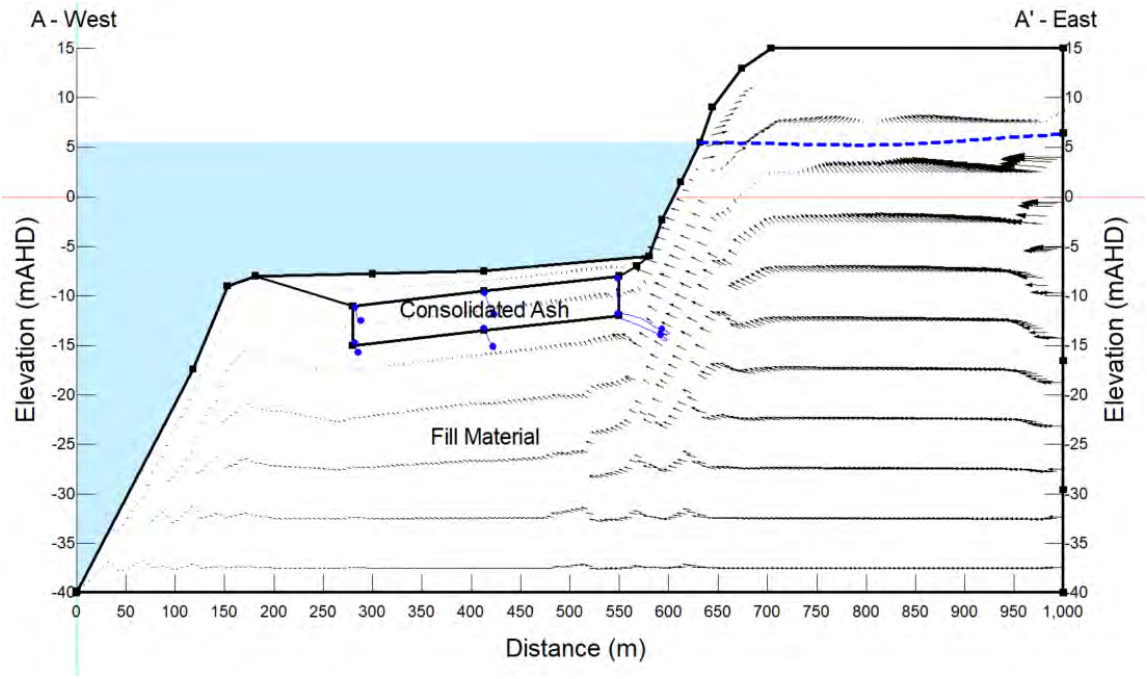

Figure 9-36 Particle Tracking 2030 to 2130 Simulation – Scenario 3 Sensitivity Analysis

Table 9-12 provides tracking information on each particle within the consolidated leached ash domain.

Table 9-12 Particle Tracking – Scenario 3 Sensitivity Analysis

Particle		1	2	3	4	5	6
Travel Time (days)		36,500	36,500	36,500	36,500	36,500	36,500
Initial Location	X-Coordinate (m)	282	282	413	548	548	413
	Y-Coordinate (m)	-11	-15	-13	-12	-8	-10
Final Location	X-Coordinate (m)	288	285	422	591	593	423
	Y-Coordinate (m)	-12	-16	-15	-14	-13	-12
Total Distance Travelled (m)		8	5	14	58	63	14
Average Speed (m/d)		$2x10^{-4}$	$1x10^{-4}$	$4x10^{-4}$	$2x10^{-3}$	$2x10^{-3}$	$4x10^{-4}$

Particle 5 is observed to have travelled approximately 63 m, however the particle pathway is not linear along the x axis; overall, it has travelled 45 m in an easterly direction but at a tangent before reversing direction as groundwater flow with the model domain evolves (**Figure 9-37**).

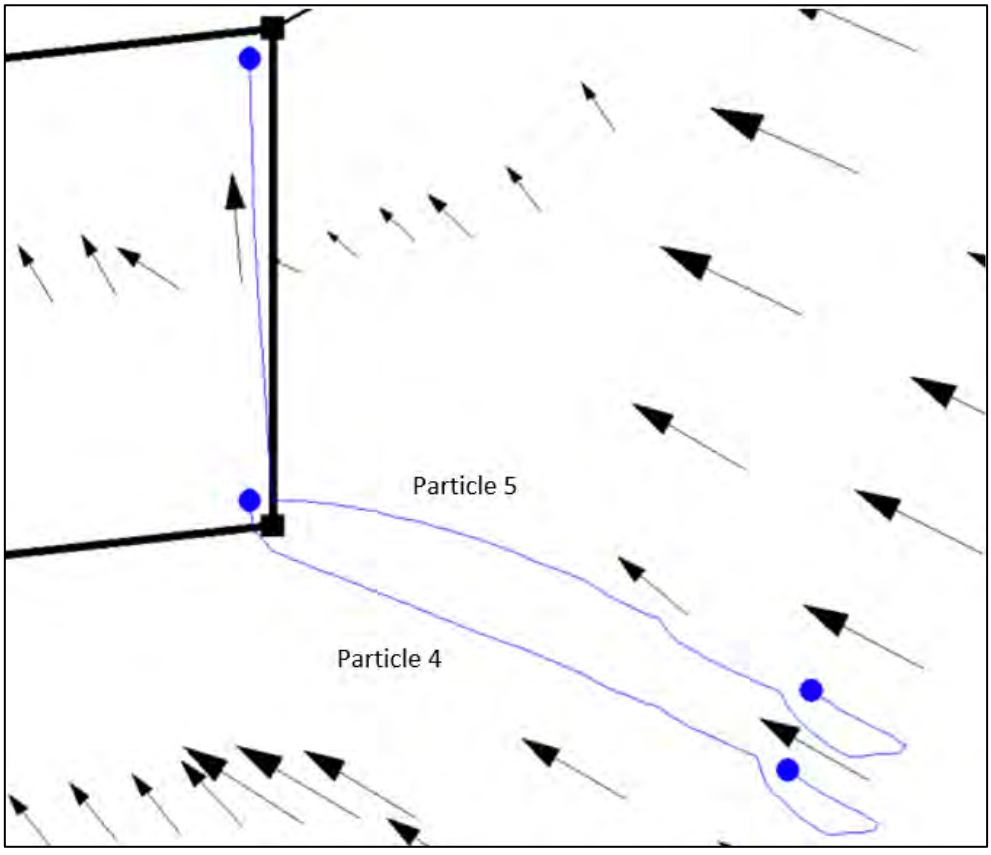

Figure 9-37 Scenario 3 Sensitivity Particles 4 and 5 Travel Pathways at 2130 yr Time-step

9.10.4.3 Sensitivity Analysis Rapid Fill

A fill rate was used to depict an event where the water body fills after a storm event and prolonged heavy rainfall. This has been simulated as a 15 GL volume of water added in 12 months (2023) at a single time step.

The model project definitions for the sensitivity analysis of a rapid fill are provided in **Table 9-13**.

Table 9-13 Sensitivity Analysis – Scenario 3 Rapid Fill Project Definitions

Scenario 3	Time Frame	Physical Processes	Water	Time	
				Duration (days)	Steps
Transient	2016 to 2023	Water	Default parameters	2,564	50

The steady-state model which was established for Scenario 1a was also used to derive the initial conditions for the transient model in Scenario 3 rapid fill sensitivity analysis.

This sensitivity analysis simulates the addition of 15 GL volume of water in 12 months (2023) at a single time step (**Figure 9-38**).

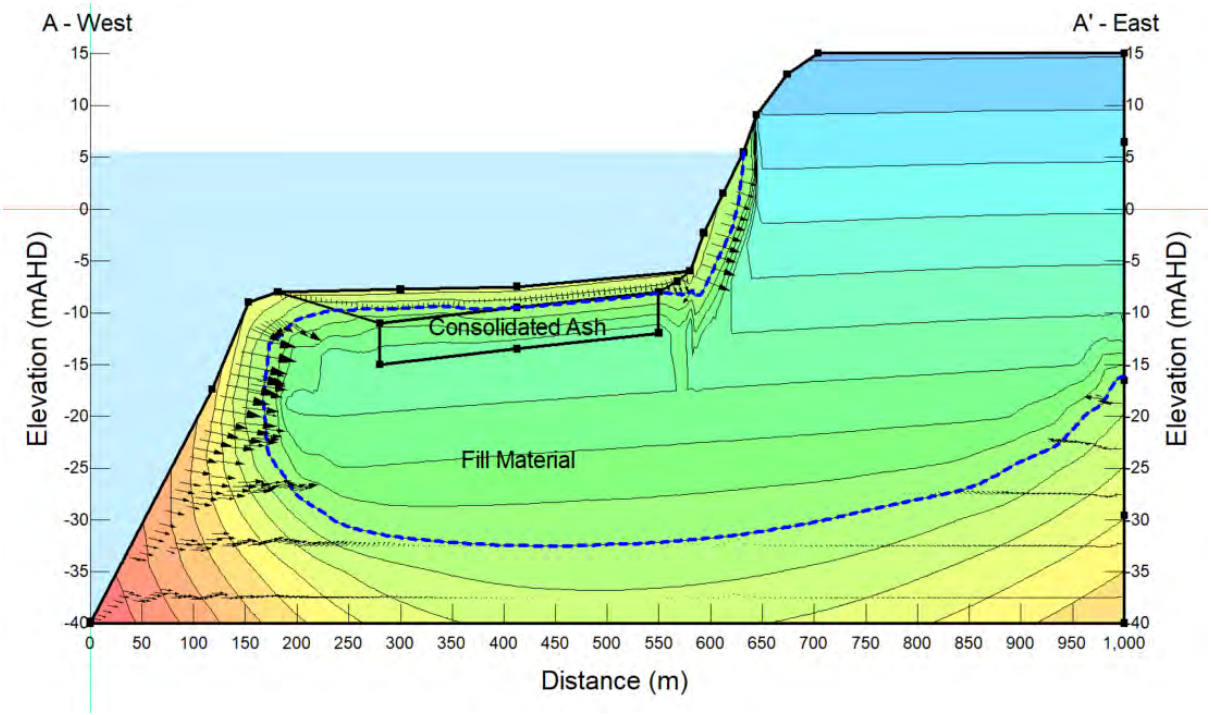

Figure 9-38 Sensitivity Analysis Rapid Fill Transient Time-Step 7.02 Years (2023)

Due to the rapid increase in the total head of the water body BC, there is a steep hydraulic gradient in the fill material towards the eastern BC (year 2023). To observe the change in the water table hydraulic gradient and elevation as the eastern BC total head increases, the simulation was extended by 75 years to 2098 (**Figure 9-39**).

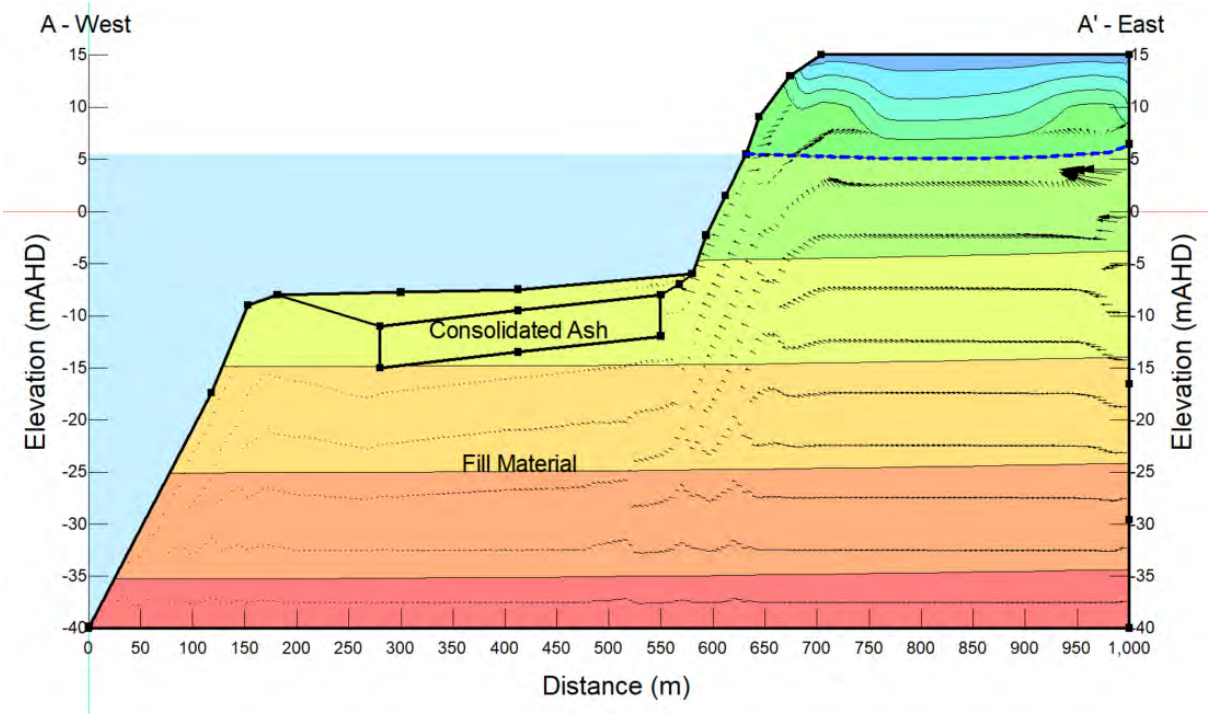

Figure 9-39 Sensitivity Analysis Rapid Fill Transient Time-Step 82 Years (2098)

In **Figure 9-39** the groundwater flow direction has reversed to a westerly direction towards the water body.

Particle Tracking – Rapid Fill

Particle tracking has been used to view single particle flow paths within the transient simulations. The particle flow paths are not the same as the flow paths computed in steady-state simulations, as these paths are known through the entire model domain as the flow is established. With transient particle flow paths, a particle has infinite vectors to flow over time and it is not known what the particle path will be until the simulations have completed.

The time-step selected for particle placement is 10.4 years and represents 2026, at which point the CLA is simulated to be saturated. The particle tracking simulation was run for a total of 100 years within a 110 year total simulation period. This represents a total time frame 2016 through to 2126. Particle locations are the same as those provided in **Figure 9-22**.

The groundwater flow direction is westerly and discharges to the water body (**Figure 9-40**).

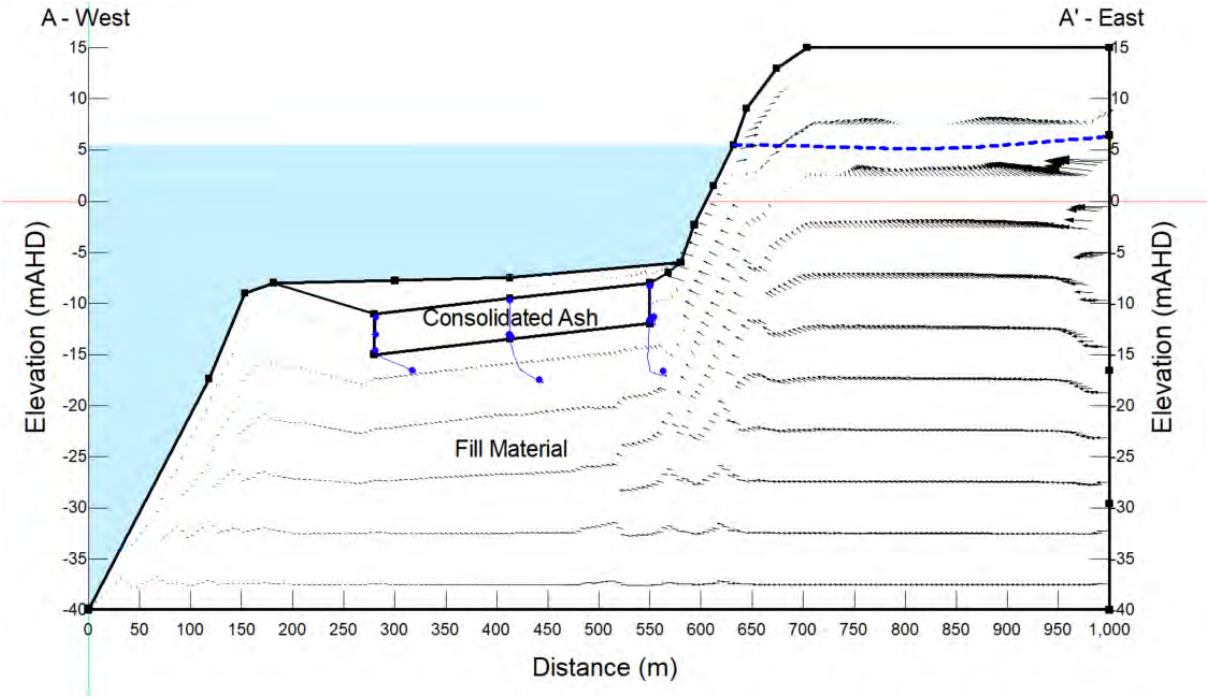

Figure 9-40 Particle Tracking 2026 to 2126 Simulation – 100 Year Time Frame

Table 9-14 below provides tracking information on each particle within the CLA domain**.**

Table 9-14 Particle Tracking 100-Year Time Frame

Particle		1	2	3	4	5	6
Travel Time (days)		15,048	17,929	17,610	18,250	18,250	18,250
Initial Location	X-Coordinate (m)	282	281	413	549	549	413
	Y-Coordinate (m)	-11	-15	-13	-12	-8	-10
Final Location	X-Coordinate (m)	282	318	442	563	554	414
	Y-Coordinate (m)	-13	-17	-18	-17	-11	-13
Total Distance Travelled (m)		2	43	38	26	11	6
Average Speed (m/d)		$5x10^{-5}$	$1x10^{-3}$	$1x10^{-3}$	$7x10^{-4}$	$3x10^{-4}$	$2x10^{-4}$

Particle 2 is observed to have travelled approximately 43 m, however the particle pathway is not linear along the x axis; overall, it has travelled 37m in an easterly direction but at a tangent before reversing direction as groundwater flow with the model domain evolves.

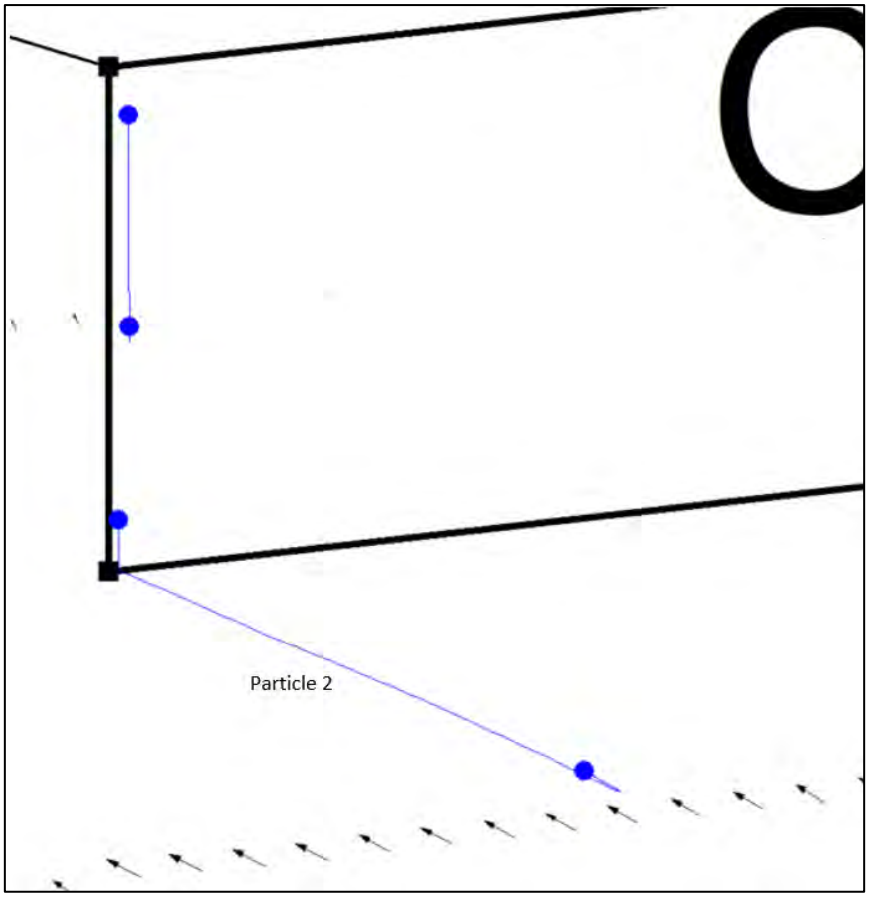

Figure 9-41 Particles 2 Travel Pathways at 2126 yr Time-step

9.11 Summary and Conclusions

Three scenarios have been developed using SEEP/W that simulate the current and future anticipated flow path regime in the vicinity of the CLA/clay-rich liner, fill material, and the water body.

The outcomes of the simulated scenarios indicate that particles representing a conservative constituent (not subject to attenuation or retardation) within the CLA do not have the potential to migrate in groundwater to either the natural in-situ DBF and BF or to the water body within the simulated time frames for groundwater recovery. These time frames consisted of a natural fill option from 2016 to 2062 (Scenario 2) and a fast fill option from 2016 to 2031 (Scenario 3).

Breakthrough and migration of a conservative constituent from the CLA to the natural in-situ DBF and BF is unlikely to occur under either a natural fill (Scenario 2) or a fast fill (Scenario 3). During Scenario 2, an easterly (i.e., movement from pit water into formation) groundwater flow exists until year 2090 of the simulation. After approximately 43 years, the groundwater flow direction changes towards the west. In the first 100 years, under this scenario a conservative particle within the CLA is estimated to move no more than 46 m and no more than 49 m in 200 years. During Scenario 3, an easterly groundwater flow exists for less than 20 years (between 2030 and 2050) before reversing to a westerly flow. In the first 100 years, under this scenario a conservative particle within the CLA is estimated to move no more than 38 m and no more than 41 m in 200 years.

Sensitivity analysis used a higher hydraulic conductivity for the CLA which is similar to the surrounding fill material. Under this sensitivity a conservative particle within the CLA is estimated to move no more than 63 m (under the fast fill scenario). This sensitivity analysis is valid for estimating the travel distance of a particle just outside the CLA (within fill material), as the hydraulic conductivities adopted for the fill material and CLA are $1x10^{-6}$ and $2.93x10^{-6}$ m/sec, respectively.

Additional sensitivity analysis simulated a rapid fill, where the water body reached a surface water elevation of 5.5 mAHD within 1 year. This assumes the addition of 15 GL of water to the water body after a storm event and prolonged heavy rainfall between 2022 and 2023. In the first 100 years, under this scenario a conservative particle within the CLA is estimated to move no more than 43 m.

It should be noted that the background groundwater quality has not been taken into consideration for this modelling review. There is currently no groundwater within the vicinity of the CLA deposit (groundwater seepage is occurring in the vicinity of DBG MB6, approximately 500 m distant from CLA area). The aim of this modelling task was to conduct a high-level assessment of the hydraulics of particle flow within the model domain. By using particle tracking (without attenuation or retardation) the conservative assessment of constituent migration could be assessed. As the outcome of this task was that particle tracking did not suggest significant migration of particles (after 200 years) from the CLA, through the clay-rich layer and into the fill material, it is concluded that a fate and transport modelling assessment was not necessary.

The low permeability of the CLA and surrounding clay-rich layer are providing an effective advective control and limit the potential for the migration of constituents within the surrounding fill material under saturated conditions.

9.12 Supplementary Hydrogeological and Geochemical Modelling

Following the development of the SEEP/W numerical model, the calibrated regional numerical model was used to explore further the short-term groundwater flow surrounding the water body during and after a fast fill scenario lasting twelve months. The geochemical modelling program PHREEQC was also used to conduct a simple mixing model to estimate the evolving water body quality during a fast fill scenario using a water quality representative of UEVF groundwater. A fast fill of the water body (i.e., over 12 months) is considered to be representative of the 'worst-case' scenario for the potential magnitude of groundwater flow radially outwards form the water body over the short-term.

9.12.1 12-Month Fast Fill Scenario

The long-term water body filling strategy is exploring the use of UEVF groundwater as a source of water to augment the filling process as part of the mine rehabilitation and closure planning.

The regional Anglesea numerical groundwater model was originally developed to support a bulk entitlement application for groundwater abstraction by Barwon Water. A new regional numerical model has been developed and is being used to inform Alcoa's potential licence application process for the proposed abstraction of groundwater from the UEVF to accelerate the filling of the water body in the former coal mine. This specific task has used quantitative outputs from the updated numerical model which have been used for the qualitative assessment of the water body under 12 months UEVF fill (augmentation) scenario.

The quality of water used to fill the void will potentially influence the chemistry of the developing water body. PHREEQC is a geochemical modelling program which can be used to assess the effects of mixing varying volumes of different quality water sources in conjunction with evaporation to estimate how the future water body quality will evolve.

The following sections provide an account of the geochemical modelling approach used to develop a PHREEQC model using the regional numerical model (MODFLOW). Volumetric outputs and surface water and groundwater quality inputs were used to assess water body quality recovery under a 12-month UEVF fill scenario using groundwater abstracted from the UEVF. This scenario was selected for the initial model scenario as it represents using UEVF water as the largest proportion of water used to fill the water body over the shortest (but still reasonable) amount of time. Longer scenarios (such as 10 years) still use the UEVF as the major contributor of water in the overall water balance but the contributions of rainfall, sidewall run-off and leakage from the DBF/consolidated fill will be greater but currently less easily defined that the UEVF volumes. The level of confidence associated with longer model runs will therefore increase over time as more data is collected.

9.12.1.1 Regional Numerical Model MODFLOW outputs

EHS Support requested from GroundwaterLogic Pty Ltd (who run the regional groundwater model scenarios for Alcoa and Barwon Water) the following MODFLOW quantitative outputs (**Table 9-15**):

Table 9-15 Water Volume Inputs and Outputs over 12 months

Water Balance Data		Volumes (ML)
Natural Inputs		
1	Leakage from ASA	<1
2	Natural groundwater inflow into the waterbody (from DBF)	455
3	Groundwater inflow into the waterbody (from UEVF)	626
4	Rainfall input to water body	303.5
5	Side wall run-off into water body	
Augmentation		
6	Augmented (modelling purposes only) UEVF Groundwater	17,464
Natural Outputs		
7	Evaporation output from water body	422

The data covered a time frame of 12 months and a final water body elevation of at least 5.5 mAHD. The final elevation of the water body for the 12 months fill scenario is 5.81 mAHD. The data was provided as 2 weekly timesteps for a total of 24 timesteps during the augmentation period.

During the augmentation period, groundwater contribution from the ASA was negligible (less than $2x10^{-4}$ ML per timestep) and was discounted from the water balance calculations. Outflow from the water body into the UEVF or the DBF and BF was also not accounted for in the water balance as it did not have a qualitative influence on the water body development and the augment volumes accounted for the loss of this water from the system. Localised catchment and sidewall runoff into the water body was small (less than 2 ML per timestep) and although not accounted for qualitatively, the volumes have been combined with the rainfall inputs. Evaporation from the water body is considerable and the volumes are compensated by additional water volumes from the UEVF, i.e., total groundwater (natural and augmented) from the UEVF into the water body is 18,090 ML for a 12 month fill scenario.

Despite the 12-month fast fill, 98 percent of the model realisations (147 of 150) indicate that all the particles migrating from the water body circumference into the surrounding aquifers, terminate within the mine lease area over the simulation period (2023 to 2066). All particles are also simulated to ultimately discharge to the water body because it forms a groundwater sink for all aquifers in the long term. In Australian post closure mine cases, steady state groundwater flow conditions are represented by radial groundwater in-flow because evaporation from the water body exceeds the rate of water discharge (from surface water and groundwater) into the water body.

9.12.1.2 Water Quality inputs

Water quality data was used from a single groundwater and surface water monitoring event in early November 2022. The event was selected as it is the most recent data capture using the broad analytical suite and samples from both the UEVF and DBF and BF aquifers. The largest contributors to the developing water body (the waterbody itself and the UEVF) under an augmentation scenario also have stable geochemistry profiles over time.

Major and selected minor ions were used to characterise the water inputs. The major ions were used to ensure an acceptable ionic balance and the minor ions for the acid producing and buffering characteristics (**Table 9-16** and **Table 9-17**).

Table 9-16 Water Composition – Major Ions

Sample Location	Date	pH	Sodium mg/L	Potassium mg/L	Calcium mg/L	Magnesium mg/L	Chloride mg/L	Sulfate (as SO4) mg/L	Alkalinity (as CaCO3) mg/L
Water Body	9/11/2022	3.6	250	19	87	82	427	626	<1

9.12.1.3 PHREEQC Model Development

The geochemical conceptual model for the water body development was based on an assumed input of water at each timestep of water quality derived from the DBF and BF, UEVF, and rainfall and the ratios (or volumes) from the regional MODFLOW model. Water (as H_2O) was removed at each timestep (as evaporation). Solution composition was equilibrated with mineral species and atmospheric gasses at each timestep. Oversaturated (SI>0) mineral phases were removed (precipitated) from the solution. At the end of each timestep a proportion (as a ratio for the next timestep simulation) of the final solution composition was used to form the water body component of the next timestep. In total 24 timesteps (representative of 1 year) were simulated. The Minteq version 4 database was used for all simulations.

9.12.1.4 PHREEQC Outputs

The water body quality development over the 24 timesteps (1 January 2023 to 1 January 2024) has been plotted in **Figure 9-42** (major ions) and **Figure 9-43** (minor ions) below. As the volume of the water body increases with the addition of groundwater and surface water, fluctuations in major and minor ion chemistry are observed.

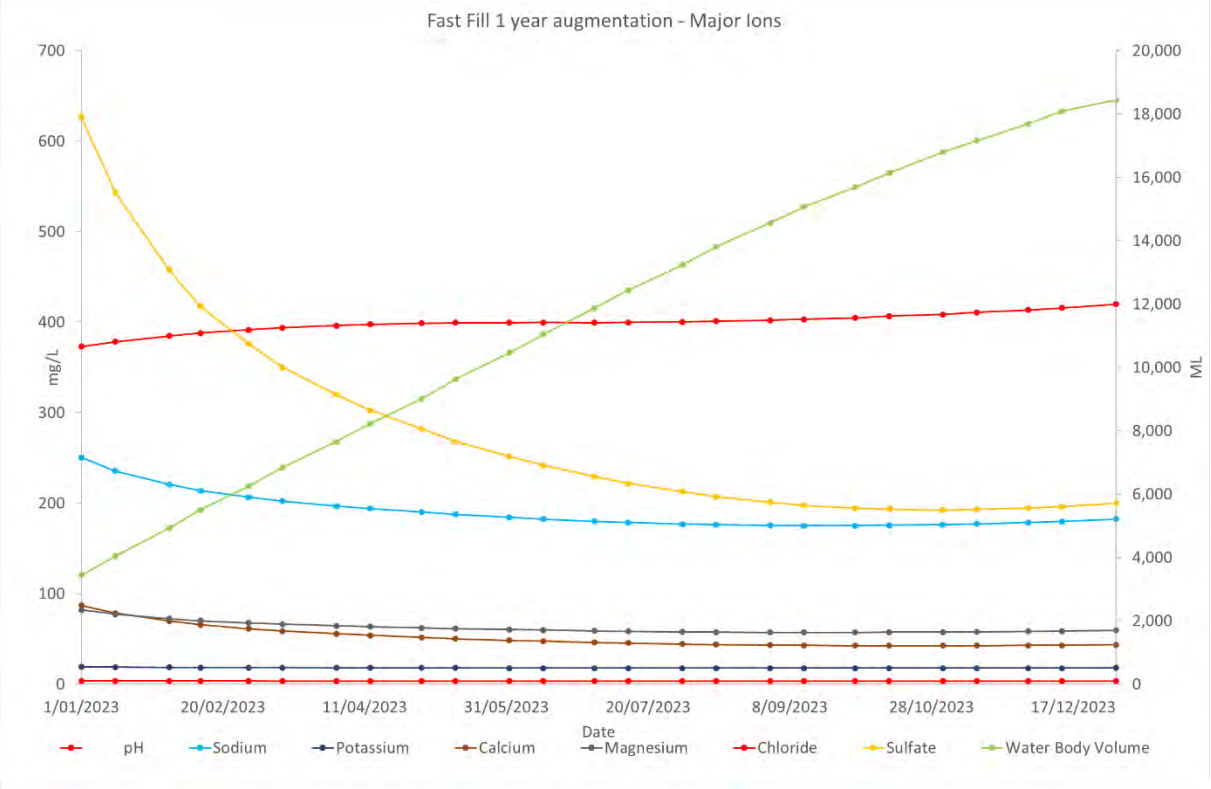

Figure 9-42 Fast Fill 1 Year – Major Ions

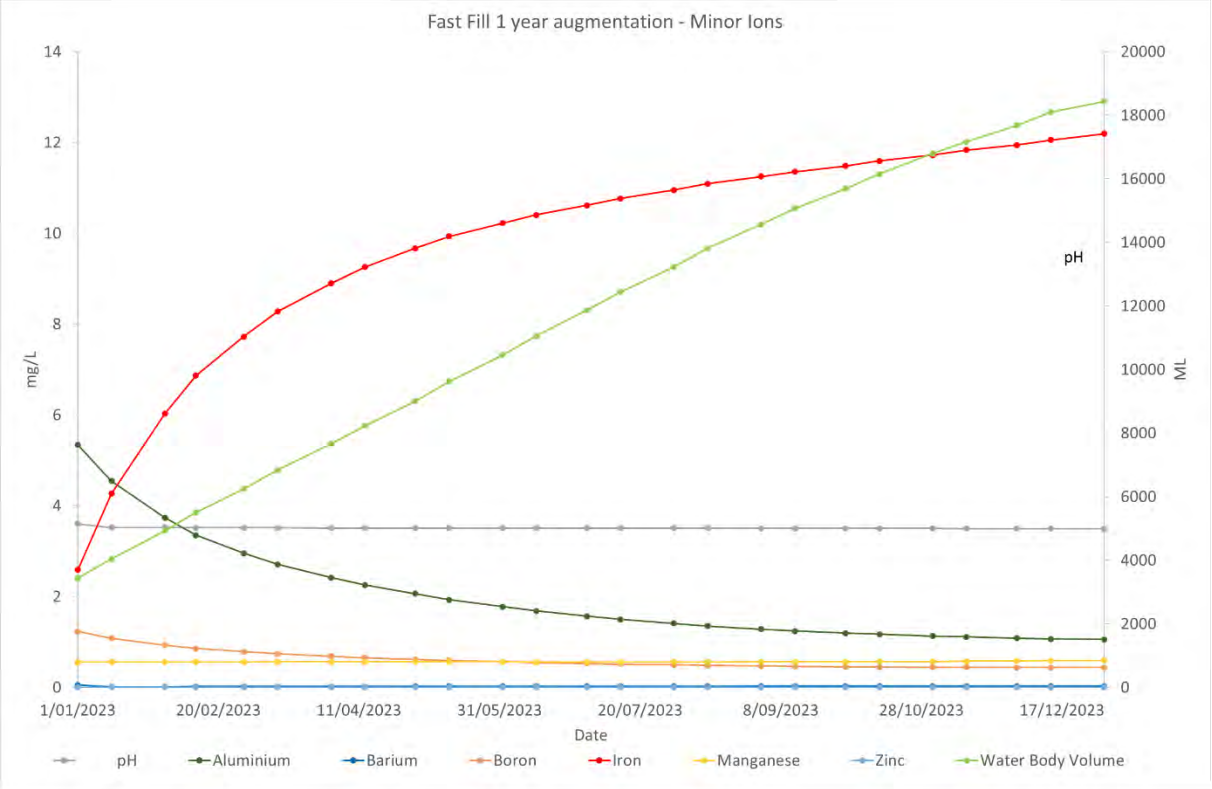

Figure 9-43 Fast Fill 1 Year – Minor Ions

Although the pH of the UEVF water is only slightly acidic (pH 6.82) the potential acidity loading is high based on the concentration of iron (and to a lesser extent aluminium, manganese, and zinc). The overall increase in iron concentration at the end of the augmentation period is sufficient to maintain the acidic nature of the water body with a slight decrease in the pH from 3.6 to pH 3.5. The final water body quality is improved with lower concentrations of aluminium (5.34 mg/L to 1.06 mg/L), barium (0.05 mg/L to 0.03 mg/L), boron (1.23 mg/L to 0.44 mg/L), zinc (0.58 mg/L to 0.14 mg/L), and major ions (sodium, potassium, calcium, magnesium, and sulfate). The decrease in metal and major ion species is due to dilution (lower concentrations in UEVF groundwater) although precipitation of mineral phases (iron minerals including ferrihydrite) could potentially affect metal concentrations (via co-precipitation) in the long term. There are increases in the concentrations of chloride (373 mg/L to 420 mg/L), iron (2.59 to 12.19 mg/L), and manganese (0.56 mg/L to 0.60 mg/L).

The PHREEQC model ran successively with no convergence issues or errors.

9.12.1.5 Additional Scenarios

In addition to the 12 months scenario, four and ten year fill scenarios were also simulated using an extrapolation of the original numerical model data (**Table 9-18**). This assumption will underestimate the natural inflow contributions especially from the UEVF but the augmentation volume has compensated for this shortfall. Rainfall contribution will increase over time and sidewall runoff will decrease however these are proportionally minor volumes compared to augmentation. Evaporation will also increase over time, so evapoconcentration is underestimated.

Table 9-18 Comparison of One, Four, and Ten Year Fill Scenarios

Fill Scenario	pH	Sodium	Potassium	Calcium	Magnesium	Chloride	Sulfate	Aluminium	Barium	Boron	Iron	Manganese	Zinc
	S.U.	*mg/L*											
Initial	3.60	250	19	87	82	373	627	5.34	0.05	1.23	2.59	0.56	0.58

Final 4yr	3.50	196	17	48	63	410	267	1.09	0.02	0.44	0	0.61	0.20
Final 10yr	3.54	241	16	61	77	413	441	1.23	0.01	0.48	0	0.70	0.34

[40] PHREEQC model precipitates iron (as iron mineral species) if oversaturated, in reality the mine water is supersaturated with iron

9.12.1.6 Summary and Conclusions

The regional numerical model and a PHREEQC geochemical model has been used to estimate the evolution of water body quality using measured groundwater and surface water chemistry over a 1 year timeframe. The final water body chemistry is estimated to have lower concentrations of metals and major ions (with the exception of chloride and manganese) and slightly more acidic (**Table 9-19**). The existing water body and UEVF chemistry exert a strong acidity buffering over the final water body pH.

Predicted variation in water body quality between a 1, 4, and 10 year fill is dependent upon the water quality of the UEVF groundwater used as the primary source of amendment water. The geochemical modelling has used a 'fixed' water chemistry based on one sampling event in November 2022. As more data is collected for the UEVF water quality the predicted water body chemistry will be revised, reassessed, and verified against the interim water quality performance targets (WQPTs) proposed in **Section 4.7**.

Table 9-19 Initial and final Water Body Quality

Location	Unit	Water Body – Initial	Water body – Final
		Sampled 09 Nov 2022 (simulation date 01 Jan 2023)	01 Jan 2024
pH	S.U.	3.6	3.49
Sodium	mg/L	250	182
Potassium	mg/L	19	18
Calcium	mg/L	87	43
Magnesium	mg/L	82	59
Chloride	mg/L	373	420
Sulfate (as SO4)	mg/L	627	200
Total alkalinity (as CaCO3)	mg/L	<1	<1
Aluminium	mg/L	5.34	1.06
Barium	mg/L	0.05	0.03
Boron	mg/L	1.23	0.44
Iron	mg/L	2.59	ND[41]
Manganese	mg/L	0.56	0.60
Zinc	mg/L	0.58	0.14

9.12.2 Consolidated Leached Ash and Water Body – Simple Mixing Calculation

To evaluate the scenario where the entire CLA area is eroded and mixed into the water body, a simple mass balance approach was used to calculate the concentrations of selected analytes in the water body after mixing. The leachability analysis of CLA at pH 2.9 and the water body quality (90th percentile) have been used (**Table 9-20**) to derive the resulting water quality after mixing (**Table 9-23**). The current estimated water body volume and estimated steady-state water body volume (**Table 9-21**) have been used together with the volume of the CLA area (**Table 9-22**).

[41] ND – non detect

Table 9-20 Water Body and CLA Quality Characteristics – 90th Percentile Values

Analyte	Unit	CLA leachable Fraction pH 2.9	Water Body
Aluminium	mg/L	17.1	5.32
Boron	mg/L	10.5	1.46
Iron	mg/L	3	11.49
Manganese	mg/L	3.6	0.56[42]
Zinc	mg/L	0.1	0.38

Table 9-21 Water Body Volume

Parameter	Unit	Estimated Volume – 2024	Estimated Volume – Steady State
Volume	ML	3,442	17,689

Table 9-22 CLA Physical Characteristics

Parameter	Unit	Value
Area	m^2	45,602
Thickness	m	4
Volume	m^3	182,408

Table 9-23 Water Body Quality – Before and After CLA Mixing

Analyte	Unit	Water Body – Current	Water Body After Mixing – Current Volume	Water Body After Mixing – Steady State Volume
Aluminium	mg/L	5.32	6.23	5.50
Boron	mg/L	1.46	2.02	1.57
Iron	mg/L	11.49	11.65	11.52
Manganese	mg/L	0.56[43]	0.75	0.60
Zinc	mg/L	0.38	0.39	0.38

Even if all the CLA was dispersed through the current or future steady -state water body, the resulting concentrations of aluminium, boron, iron, manganese, and zinc would be most likely be within the range of expected concentrations and with limited increase in risk to environmental values.

[42] Manganese has only recently been added to the analytical suite for the water body sampling events, therefore, currently there is only one result available
[43] Manganese has only recently been added to the analytical suite for the water body sampling events, therefore, currently there is only one result available

10 Consolidated Leached Ash Risk Assessment Matrix

In accordance with Part 3 Division 6 Section 44 of the Mineral Resources Sustainable Development (Mineral Industries) Regulations 2019 Alcoa has identified potential mining hazards and assessed risks associated with covering and submerging the CLA area located in the south-east corner of the mine.

This process involved several steps, consistent with those outlined in 'Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS' **Appendix B** (December 2020 version 1.3) (Victoria, 2020) provided by the Department of Jobs Precincts and Regions, as outlined below:

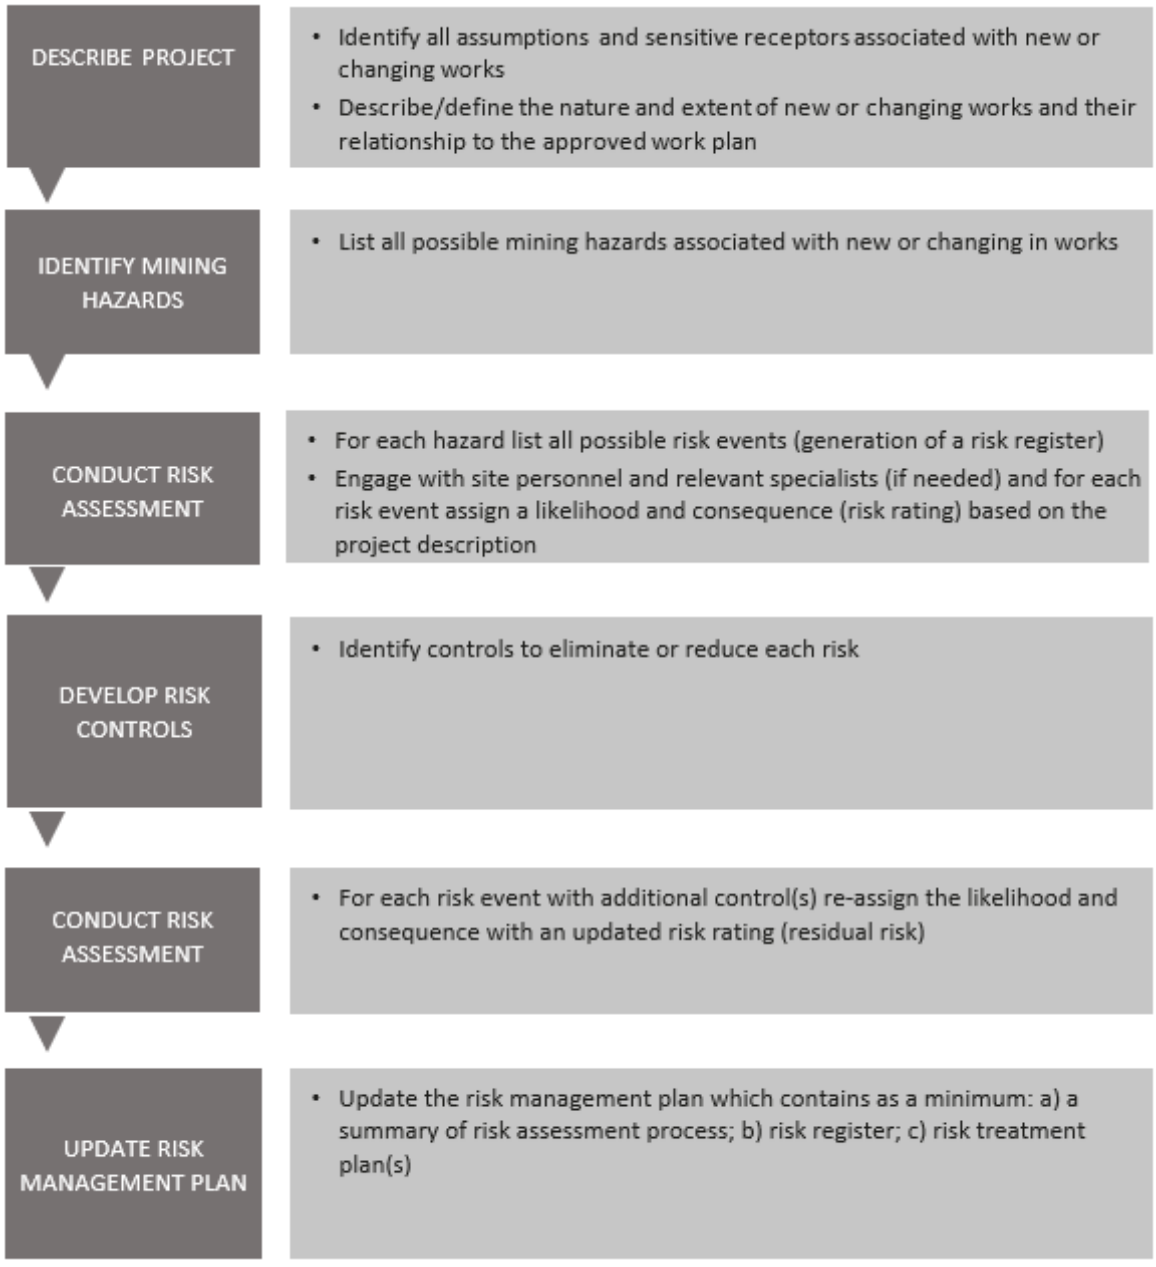

Figure 10-1 Assessment Process of Identifying Potential Hazards and Risks

The risk assessment process is intended to identify and assess all risks that the new or changing works may pose to the environment, to the public, or to nearby land, property, or infrastructure – these are known as mining hazards. The identified risks are then eliminated or minimised as far as reasonably practicable with appropriate controls (risk treatment plan).

These aspects are outlined in the sections below.

10.1 Project Description and Key Assumptions

As a key input into understanding any potential risks associated with submerging the CLA area, the results of the chemical and physical sampling have been used to inform hydraulic modelling using GeoStudio SEEP/W software (**Section 9**) with the objective of simulating:

- Hydraulic behaviour of rising water body and groundwater levels and potential groundwater seepage into the fill material under steady-state and transient conditions as the mine water body develops; and
- Particle tracking to observe movement of particles representative of a conservative (not subject to attenuation or retardation) constituent within the model domain.

Informed by the above, the intent of the Risk Assessment is to 'identify and assess all risks that the new or changing works may pose to the environment, to the public, or to nearby land, property, or infrastructure – these are known as mining hazards. The identified risks are then eliminated or minimised as far as reasonably practicable with appropriate controls (risk treatment plan).'

The new or changing works for the purpose of the risk assessment is the **submerging of the CLA during the development of the mine water body**. This remans consistent with the draft Mine Rehabilitation and Closure Plan submitted to ERR in 2017 (EHS Support, 2017), the Work Plan Variation – Progressive Rehabilitation Works approved by ERR March 2018, and the Work Plan Notification – Groundwater Pumping Test acknowledged by ERR February 2021.

Considerate of the above, the key assumptions associated with this risk assessment are outlined below.

Key Assumptions

- The CLA has been covered with at least 1 m of clay rich overburden material, with the depth of covering confirmed by 19 test pits in 2018 (**Appendix E** & **Appendix G**).
- Permeability results indicated CLA, clay-rich layer, and fill material permeabilities of less than $1x10^{-9}$ m/sec as confirmed by field sampling September 2021 and June 2022.
- The mine water body water level will develop based on a fast fill strategy using UEVF groundwater (subject to potential future licence submission to Southern Rural Water and final MCRP approval) in addition to shallow groundwater recovery and rainfall and is expected to rise from a water level of -17.4mAHD in April 2022 to approx. +5.5 mAHD over a period of about 10 years. Once the water body is full the CLA area will be submerged between approximately 12 m and 19 m below surface level.
- The mine water body will not be directly connected to the Anglesea River catchment consistent with the previous discussions with DELWP, with no engineered outlet or spillway.

- The mine water body interim WQPTs have been established based on the baseline water quality dataset for the mine water body and associated with potential changes to the mine pit water quality. A statistical approach has been adopted which uses the 10th (pH only) and 90th percentiles (**Section 4**):
  - This approach is considered to be consistent with the ongoing and accepted management of the surrounding naturally occurring background surface water systems by the local authorities and regulators which include DELWP, CCMA, and the Surf Coast Shire.
- The adopted segment classification for the UEVF is segment B.
- Based on the water quality data collected across the Power Station site, the segment classification of the DBF and BF is also Segment B as described in Table 5.2, Clause 14 of the ERS. Segment B is based on a TDS concentration range of 1,201 to 3,100 mg/L.
- The long term mine pit water body will act as a groundwater sink otherwise known as a groundwater discharge feature, for the shallow aquifer system. The DBF and BF in the vicinity of the mine pit is currently dry, however there is a potential that this part of the DBF and BF may become saturated, as the mine pit fills.
- The future mine water body will not be available for recreational purposes consistent with the draft MRCP (2017) and consistent with historical discussions with DELWP.
- The landforms surrounding the CLA area and the CLA area itself, are geotechnically safe and stable as per the Geotechnical Designs submitted as part of the Work Plan Variation – Progressive Rehabilitation Works approved by ERR March 2018, and since constructed in accordance with the approved designs.
- The cap material in particular is unimpacted by the effects of bioturbation and a range of other potential physical, biological, and chemical processes.
- The licensed mine boundary and Alcoa's land management will remain in effect until future surrender to the state, which will be done once the state accepts that Alcoa has met all of its obligations and reduced long term risk to an acceptable level, including as relating to the CLA.

10.2 Identification of Potential Mining Hazards, Risk Sources and Receptors at Risk

After operating the Anglesea mine for 46 years, inclusive of developing forward looking potential future rehabilitation and closure plans, Alcoa is appropriately informed to identify the various potential issues associated with the covering and submerging the CLA area located in the south-eastern corner of the mine.

In addition to the extensive experience that Alcoa has with the site and associated understanding of potential issues, Alcoa has undertaken various processes during the development of the draft MRCP, the mine water body filling strategy, and in particular the proposed covering and submerging the CLA area located in the south-eastern corner of the mine to ensure that it has identified all issues associated with activity so far as reasonably practical.

These processes have been implemented to ensure that all relevant risks are identified, understood and that appropriate management controls are in place. These processes also represent the measures taken to comply with the GED, relevant ERS and principles of the *Environment Protection Act 2017,* and include:

- Review of the Department of Primary Industries endorsed Work Plan for the Anglesea Mine, dated 22 September 2011 inclusive of the then incorporated mine closure plan.
- Ongoing, frequent consultation with the regulator(s) throughout development of the key concepts in support of the proposal for covering and submerging the CLA area located in the southeast corner of the mine. This includes Department of Job Precincts and Regions (DJPR) ERR, DELWP, EPA, and SRW.
- Development of the Draft Anglesea Mine Rehabilitation and Closure Plan submitted to ERR September 2017 including a detailed technical assessment (Appendix K Anglesea Mine Ash Assessment, refer to **Appendix J**), and consideration of the feedback subsequently provided by the regulators regarding the proposal for covering and submerging the CLA area located in the southeast corner of the mine.
- Review of the relevant Acts, Regulations, Reference Standards, and Guidance documents to understand the appropriately relevant legislative requirements.
- Engagement of appropriately experienced and qualified technical consultants (EHS Support) to complete the appropriate technical studies related to the CLA area, inclusive of research on similar leached ash related situations to identify successes, issues, risks, and lessons that could be applied to Anglesea former mine pit.
- Internal review by technical expertise that forms part of Alcoa's Global Asset Planning and Management Group experienced in the rehabilitation and closure of Alcoa's operating sites globally.
- Engagement of an appropriately experienced and qualified technical consultant (BlueSphere) to conduct an independent peer review of the covering and submerging the CLA area (**Section 2**).
- Completion of numerical modelling (**Section 9**) specifically related to hydraulic behaviour of rising water body and groundwater levels and potential groundwater seepage, and particle tracking to observe movement of particles representative of a conservative (not subject to attenuation or retardation) constituent within the model domain, related to the submerging of the CLA area.
- Completion of appropriate risk assessment (*this risk assessment*) to identify and assess all risks that the new or changing works may pose to the environment, to the public, or to nearby land, property or infrastructure using '*Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS'* **Appendix B** (December 2020 version 1.3) provided by the Department of Jobs Precincts and Regions.

As an outcome of the processes undertaken, a list of potential mining hazards, risk sources and sensitive receptors has been identified associated with covering and submerging the CLA area located in the southeast corner of the mine (**Table 10-1**).

As part of determining the potential sensitive receptors the following has been considered consistent with 'Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS' **Appendix B** (December 2020 version 1.3) provided by the Department of Jobs Precincts and Regions:

- Members of the public – public health, safety, amenity, and Aboriginal heritage;
- Land, property and infrastructure: neighbouring property as well as nearby infrastructure such as highways, schools, and hospitals; and
- Environment: air, water, soil, vegetation, flora, and fauna outside the work area.

Table 10-1 Potential Mining Hazards, Risk Sources, and Sensitive Receptors

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk
1	Surface Water quality	• CLA interaction with mine water body adversely impacts mine water body water quality during filling. • Adversely impacted (by CLA) mine water body water has an adverse impact on local surface water systems environmental values during filling.	• Mine water body • Anglesea River
2	Groundwater quality	• CLA interaction with groundwater adversely impacts DBF/ASA groundwater quality in the undisturbed DBF/ASA aquifers during filling. • CLA interaction with groundwater adversely impacts UEVF groundwater quality in the undisturbed UEVF aquifer during filling. • CLA ash interaction with groundwater (DBF/UEVF/ASA) adversely impacts third party users during filling. • CLA ash interaction with groundwater (DBF/UEVF) adversely impacts GDE's? during filling.	• DBF / ASA • UEVF • UEVF aquifer domestic users • LEVF Barwon Water • NOTE there are no third-party users for DBF/ASA. • GDE's Flora and Fauna
3	Erosion & Sedimentation	• Surface water run off (rain fall) reducing cover material to below 0.7m depth before being submerged. • Water body level increase eroding cover material to below 0.7m depth at shoreline interface. • Differential settlement of area during submersion resulting in cover material to below 0.7m depth. • Erosion of submerged cover material to below 0.7m depth. • Risk of bioturbation.	• Mine Water Body

10.3 Control Measures and Performance Objectives

Alcoa recognises that Anglesea mine rehabilitation and closure issues are specific to the site and dependent on a variety of factors, and that any plan and management of associated risk needs to be founded on detailed technical understanding and management strategies.

To ensure appropriate understanding of each identified issue or hazard, inclusive of potential associated risks, Alcoa initiated detailed technical studies early in the development of the plan as described in various sections above. These studies have helped inform not only the level of any identified risk, but also on the potential controls that are appropriate to manage the identified risks.

With the development of the control measures Alcoa was also then able to specify appropriate performance objectives for each combination of control measures.

Both the proposed control measures and associated performance objectives for each combination of control measures, against each potential mining hazard, are shown in **Table 10-6** further below.

10.4 Risk Assessment

The current requirements of Part 3 Division 6 Section 44 of the Mineral Resources Sustainable Development (Mineral Industries) Regulations 2019 requires Alcoa to identify potential mining hazards and assess risk associated with the new or changing works which is the submerging of the CLA area during the development of the mine water body.

Risk assessment is the process of finding, recognising, and describing the potential risks associated with the activity, identifying potential impact areas, and the potential impact(s) on these areas if the risk occurs.

With an understanding of the potential mining hazards, risk sources and receptors at risk, coupled with proposed control measures and associated performance objectives, a structured and consistent risk assessment process has been applied by Alcoa.

The risk assessment has also been **Independently Peer Reviewed** by BlueSphere (**Section 2**).

To ensure a high level of consistency with ''*Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS'* **Appendix B** (December 2020 version 1.3) published by the Department of Jobs Precincts and Regions, Alcoa has directly adopted the Risk Matrix, Consequence rating, and Likelihood ratings provided within.

The Risk Matrix Table, shown in **Table 10-2** below, provides an overall risk rating for each identified mining hazard considerate of the proposed controls with regard to the assessed consequence and likelihood of each hazard occurring.

Table 10-2 ERR Risk Matrix

Figure A1: ERR Risk Matrix

Likelihood	Insignificant	Minor	Moderate	Major	Critical
Almost Certain	Medium	High	Very High	Very High	Very High
Likely	Medium	Medium	High	Very High	Very High
Possible	Low	Medium	Medium	High	Very High
Unlikely	Low	Low	Medium	High	High
Rare	Low	Low	Medium	Medium	High
	Consequence				

Table Notes:
(Source: *Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS'* **Appendix B** (December 2020 version 1.3) published by the Department of Jobs Precincts and Regions)

The potential consequence associated with each assessed risk was assessed using a series of descriptors described in the **Table 10-3** below, which were assessed separately for each of the following potential impact areas:

- "Any member of the public" - public health, safety, amenity, and Aboriginal heritage;
- "Land, property and infrastructure" – *beyond the boundary of the licence area*; and
- "The environment" – air, water, soil, vegetation, flora, and fauna species *other than for planned and approved disturbances within the licence area.*

Table 10-3 ERR Consequence Descriptions

Severity	Consequence For "any member of the public" – Public Health, Safety, Amenity, and Aboriginal Heritage	Consequences For "land, property and infrastructure" Beyond the Boundary of the Licence Area	Consequences For "the environment" – Air, Water, Soil, Vegetation, Flora, and Fauna Species Other Than For Planned and Approved Disturbances Within the Licence Area
Critical			
Hazard has critical impact, in terms of severity and/ or duration. Treatment or remediation effort is required, although some effects may be irreversible. Remediation of environmental contamination would require significant private and public resources. Hazard event would be the subject of widespread community outrage.	**Public Health and Safety** One or more fatalities or life-threatening injuries or illness. Public exposed to a severely debilitating chronic health impact or life-threatening hazard. One or more injuries resulting in permanent disablement. **Public Amenity** Community or multiple individuals continuously experience major losses of amenity from dust, odour, fumes, noise, or other similar hazards over periods of weeks or longer. **Aboriginal Heritage** Harm to features and/or places of Indigenous cultural value. **Heritage** Irreversible damage, or destruction of a place, object or historical archaeological site listed on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay.	**Land and Land Uses** Permanent loss of production from primary production land >1h0 ha. Loss of annual- seasonal primary production from >100 ha of land. Irreversible or long-term environmental damage (with rehabilitation taking years or longer) to >1 ha of National Park or other conservation reserve. **Public and Private Property** Total damage to private or public property or infrastructure or loss of income resulting from this damage >$10 million. Total loss of value of private property equivalent to >$10 million. **Services Provided by Infrastructure** Important community services (e.g., transport, energy, health, telecommunications, education, water) suspended or significantly disrupted for extended period (weeks or longer).	**Environmental Contamination Event** Environmental contamination event (of air, soil-land and/or water) of a magnitude that a State-level incident response is required. Incident response, clean-up and rehabilitation expected to run for years and/or cost ≥$10 million. **Native Vegetation, Flora Species or Fauna Species** Environmental contamination event or other form of environmental damage leading to bioregional, State, or national extinction of listed threatened species of native flora or fauna or vegetation community. Irreversible or long-term (years) damage or environment harm to ≥10 ha of native vegetation (not listed threatened vegetation community) or to ≥1 ha listed threatened native vegetation community. Deaths of hundreds (or more) of listed native flora or fauna species or native mammals. Contamination or other environmental damage leading to deaths of native fauna well beyond (>1 km) the boundaries of the operation. **Surface Water or Groundwater** Contamination of surface water/ groundwater aquifer leading to disruption of environmental values as defined by Environment Reference Standard (VGG2021S245) for more than year.

Severity	Consequence For "any member of the public" – Public Health, Safety, Amenity, and Aboriginal Heritage	Consequences For "land, property and infrastructure" Beyond the Boundary of the Licence Area	Consequences For "the environment" – Air, Water, Soil, Vegetation, Flora, and Fauna Species Other Than For Planned and Approved Disturbances Within the Licence Area
Major			
Hazard has major impact, in terms of severity, duration and/ or frequency of occurrence. Treatment or remediation effort is required. Some effects may be irreversible. Remediation of environmental contamination would require significant private and public resources. Hazard event would be the subject of widespread community concern.	**Public health and safety** One or more injuries or illness requiring surgery or resulting in long-term disablement. Public exposed to a hazard that results in hospitalisation for treatment from injury or illness. **Public amenity** Community or multiple individuals regularly experience (weekly-monthly basis) major losses of amenity due to dust, odour, fumes, noise, or other similar hazards for multiple days on end. **Heritage** Damage to a place, object or historical archaeological site listed on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay. Removal or relocation of elements associated with places, objects, or historical archaeological sites.	**Land and land uses** Permanent loss of production from primary production land <10 ha. Loss of annual- seasonal primary production from 10–100 ha of land. Irreversible or long-term environmental damage to <1 ha of National Park or other conservation reserve or to ≥10 ha of other public land. Reversible damage to ≥1 ha of National Park or other conservation reserve or to ≥10 ha of other public land. **Public and private property** Total damage to private or public property or infrastructure or loss of income resulting from this damage $1–10 million. Total loss of value of private property equivalent to $1–10 million. **Services provided by infrastructure** Important community services (e.g., transport, energy, health, telecommunications, education) suspended or significantly disrupted for days or experiencing minor disruptions for long periods (weeks or longer).	**Environmental contamination event** Environmental contamination event (of air, soil-land and/ or water) of a magnitude that would necessitate a regional emergency management incident response. Clean-up and rehabilitation expected to run for months and/or cost $1–10 million. **Native vegetation, flora species or fauna species** Environmental contamination event or other form of environmental damage leading to local extinction of listed threatened species of native flora or fauna or vegetation community. Deaths of up to ~100 listed threatened flora or fauna species or native mammals. Major damage or environment harm to 1–10 ha of native vegetation (not listed threatened vegetation community) or to <1 ha listed threatened native vegetation community that will be irreversible or take years to recover from. **Surface water or groundwater** Contamination of surface water/ groundwater aquifer leading to disruption of environmental values as defined by Environment Reference Standard (VGG2021S245) for up to one year.

Severity	Consequence For "any member of the public" – Public Health, Safety, Amenity, and Aboriginal Heritage	Consequences For "land, property and infrastructure" Beyond the Boundary of the Licence Area	Consequences For "the environment" – Air, Water, Soil, Vegetation, Flora, and Fauna Species Other Than For Planned and Approved Disturbances Within the Licence Area
Moderate			
Hazard has moderate, noticeable impact, in terms of severity, duration and/ or frequency of occurrence. Moderate treatment or remediation effort may be required. Hazard event would be the subject of limited community concern.	**Public health and safety** One or more injuries or illness requiring treatment by a physician or hospitalisation. Public exposed to a hazard that results in injuries or health effects requiring treatment by a physician. **Public amenity** Community or multiple individuals regularly (weekly- monthly basis) experience significant loss of amenity from dust, odour, fumes, light, noise, vibration, or other similar hazards. **Heritage** Works to a place, object or historical archaeological site that will not alter the cultural significance as stated on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay.	**Land and land uses** Loss of annual-seasonal primary production from <10 ha of land. Short-term (days- weeks) disruption to 10–100 ha of primary production land. Reversible damage to <1 ha of National Park or other conservation reserve or to <10 ha of other public land. **Public and private property** Individual hazard event causes total damage to private or public property or infrastructure or loss of income resulting from this damage $50k–$1 million. Individual hazard event causes total loss of value of private property equivalent to $50k–$1 million. **Services provided by infrastructure** Important community services (e.g., transport, energy, health, telecommunications, education) suspended or significantly disrupted for up to 1 day or experiencing minor disruptions for weeks.	**Environmental contamination event** Environmental contamination event (of air, soil-land and/ or water) with clean-up and rehabilitation expected to run for weeks and cost $10k–$1 million. **Native vegetation, flora species or fauna species** Environmental contamination event or other form of environmental damage leading to deaths of a small number of listed threatened flora or fauna species or native mammals. Reversible damage or environmental harm to <10 ha of non-listed native vegetation community or <1 ha of listed native vegetation community. **Surface water or groundwater** Localised contamination of surface water/groundwater aquifer leading to disruption of environmental values as defined by Environment Reference Standard (VGG2021S245) for weeks to months.

Severity	Consequence For "any member of the public" – Public Health, Safety, Amenity, and Aboriginal Heritage	Consequences For "land, property and infrastructure" Beyond the Boundary of the Licence Area	Consequences For "the environment" – Air, Water, Soil, Vegetation, Flora, and Fauna Species Other Than For Planned and Approved Disturbances Within the Licence Area
Minor			
Hazard is perceived but has minor and typically temporary effects. Some remediation may be required	**Public health and safety** One or more injuries or illness requiring first aid treatment. Public exposed to a hazard that could cause injuries or adverse health effects requiring first aid treatment. **Public amenity** Dust, odour, light, fumes, vibration, or other similar hazards infrequently (no more than monthly) have a minor effect on the amenity of the community or individuals. **Heritage** Isolated damage to regionally or locally significant natural or historic heritage features that is readily rectified.	**Land and land uses** Minor damage to agricultural land or public land not requiring active rehabilitation. Temporary and small-scale disruption to agricultural production (days, 1–10 ha). **Public and private property** Total damage to private or public property or infrastructure $1–50k. Total loss of value of private property equivalent to $1–50k. **Services provided by infrastructure** Important community services (e.g., transport, energy, health, telecommunications, education) suspended or significantly disrupted for short period (hours).	**Environmental contamination event** Minor environmental contamination event (of air, soil-land and/or water). Clean- up and rehabilitation may be required, but can be completed within days. **Native vegetation, flora species or fauna species** Minor damage or environment harm to <1 ha of native vegetation (not listed threatened vegetation community) that can be recovered in weeks to months. Minor contamination or other environmental damage that affects native fauna populations but does not kill individuals or disrupt breeding or other important ecological processes. **Surface water or groundwater** Minor contamination of natural waterway or wetland occurs, but water quality remains within applicable EPA or ANZECC guidelines for existing beneficial uses. Water extraction or diversion reduces surface water flows or groundwater available for environmental uses, but with no detectable effect on dependent species or ecosystems and carried out within terms of water licence.

Severity	Consequence For "any member of the public" – Public Health, Safety, Amenity, and Aboriginal Heritage	Consequences For "land, property and infrastructure" Beyond the Boundary of the Licence Area	Consequences For "the environment" – Air, Water, Soil, Vegetation, Flora, and Fauna Species Other Than For Planned and Approved Disturbances Within the Licence Area
Insignificant			
Impacts are barely recognised and/or quickly recovered from. No specific remediation required.	**Public health and safety** An injury or ailment that does not require medical or first aid treatment. **Public amenity** Dust, odour, light, fumes, vibration, or other similar hazards infrequently (no more than monthly) contribute to a small reduction in the amenity of the community or individuals.	**Land and land uses** Minor, temporary disruption to primary production (<days) from <1 ha of land. **Public and private property** Total damage to private or public property or infrastructure <$1k. Total loss of value of private property equivalent to <$1k. **Services provided by infrastructure** Important community services (e.g., transport, energy, health, tele-communications, education) maintained, but experiencing minor disruptions or delays.	Hazard event with minimal environmental impact and no noticeable effect beyond the immediate occurrence or expression of the hazard.

(Source: *Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS'* **Appendix B** (December 2020 version 1.3) published by the Department of Jobs Precincts and Regions)

The likelihood of each risk occurring was assessed using a series of descriptors described in **Table 10-4** below, ranging from almost certain to rare. The standard descriptors for probability include both a qualitative description, and a quantitative descriptor, with the quantitative descriptor available to be used when a statistical probability has been calculated. The probability for most of the risks was assessed in a qualitative way.

Table 10-4 ERR Likelihood Assessment Ratings

Severity	Description	Probability of Event Occurring
Almost certain	The risk event is expected to occur in most circumstances.	90–100%
Likely	The risk event will probably occur in most circumstances.	70–90%
Possible	The risk event might occur at some time.	30–70%
Unlikely	The risk event could occur at some time.	5–30%
Rare	Highly unlikely, but the risk event may occur in exceptional circumstances.	0–5%

Table Notes:
(Source: *Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS'* **Appendix B** (December 2020 version 1.3) published by the Department of Jobs Precincts and Regions)

The risk assessment team included:

Table 10-5 Risk Assessment Team

Name	Company	Title
Warren Sharp	Alcoa	Pt Henry & Anglesea Site Asset Manager
Nicci Marris	Alcoa	Environment, Health & Safety Manager
John Osborne	Alcoa	Director Asset Planning & Manager
Rebecca Fraser	EHS Support	Principal Hydrogeochemist
Chris Smitt	EHS Support	Director and Principal Hydrogeologist
Ben Petrides	EHS Support	Principal Hydrogeologist

Risk Assessment Summary

There were no very high, or high risks identified. Two medium risks were conservatively identified, with the remainder of risks assessed as low.

The medium risks related to:

- *Covered leached ash interaction with groundwater (DBF/UEVF/ASA) adversely impacts third party users during filling* – while the likelihood of this risk occurring was considered 'Rare' given the very low particle movements modelled (maximum of 49 m over 200 years), the distance to third party users, and the upward gradient from UEVF, in the event that it did occur it may result in localised contamination that may result in disruption of environmental values for that third party as defined by Environment Reference Standard (VGG2021S245) for weeks to months (and likely to exceed 1 year). In this respect the risk assessment framework and matrix are considered conservative in nature. With the nearest third party more than 400 m away (due to the extent of Alcoa mine and land management area) it is not considered conceivable from a likelihood perspective that any adverse impacts (particles) would ever reach a third-party user.
- *Surface water run off (rain fall) reducing cover material to below 0.7 m depth before being submerged / Water body level increase eroding cover material to below 0.7 m depth at shoreline interface* – While the consequence of this was assessed as minor, the likelihood was assessed as possible given that erosion could occur and it could take a number of months to address dependent on identification and timing to safely access and repair with suitable machines. It should be noted that direct discharge of ash pore water into the water body is very unlikely as maximum particle movement occurs away from the water body during filling and negligible movement towards the water body after filling. Also note that with a maximum modelled particle movement of 49 m over 200 years, then it would take approximately 2.8 years for a particle to move through 0.7m of cover material. Monthly inspections and a trigger action response plan (TARP) in place to trigger repairs to cover material in the event of observed erosion in excess of 0.3 m then would adequately address this risk.

The outcomes of the risk assessment are shown in **Table 10-6** below for the CLA area.

Table 10-6 Consolidated Leached Ash Risk Assessment

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
1.1	Surface Water Quality	• Covered leached ash interaction with mine water body adversely impacts mine water body water quality during filling	• Mine Water Body	• CLA located in the southeast corner of the mine known to be located between RL-15 and -8 m • >1 m clay rich cover material with lab sampled permeabilities less than 1x10-9 m/sec. • Lab sampled ash permeabilities less than 1x10-9 m/sec. • 'Ash Risk Assessment Hydrogeological Modelling Report' (EHS Support April 2022) using SEEP/W numerical modelling for groundwater and leached ash particle migration not expected to extend beyond the licenced mine boundary. During filling particles expected to move away from the water body. Refer to Consolidated Leached Ash Technical Assessment, EHS Support (2023) Section 9 showing maximum particle movement of 49 m away from the water body over 200 years during fast fill scenario. Direct discharge of ash pore water into the water body is unlikely as maximum particle movement occurs away from the water body during filling and negligible movement towards the water body after filling. • Independent Peer Review of Ash Modelling and Risk Assessment by BlueSphere.	• No adverse impact on mine water body water quality measured by no exceedance of 10th or 90th percentile of interim WQPTs. NOTE: - Historical water body quality is complimentary with background surface waters including Anglesea River and Salt Creek and therefore environmental value of water dependent ecosystems and species with regard to the local catchment is protected. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters. NOTE: the mine water body lies entirely within the disturbed and controlled area and will not interact with any area outside the boundary of the licensed mining area during water body filling.	Insignificant	Insignificant	Minor	Unlikely	Low	• Six monthly mine water body water quality sampling. • Six monthly groundwater water quality sampling and MB UEVF and DBG bores. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
1.2	Surface Water Quality	• Adversely impacted (by CLA) mine water body water has an adverse impact on local surface water systems environmental values during filling.	• Anglesea River	• All control measures listed in Element 1.1 above. • Mine water body is a physically closed system with no direct connection of the mine water body with Salt Creek (inlet) or Anglesea River (outlet). • Salt Creek Diversion Channel diverts high rainfall event water around the mine water body. • Natural topography of the rehabilitated landform ensures no surface water can 'spill' into the Anglesea River system below approx. RL +10 m. • The water quality of the mine water body is characterised by elevated acidity (low pH), aluminium, boron, iron and zinc, however these are generally lower in concentration within the water body (better quality) in comparison to the surrounding catchment, with the exception of Boron, which is less than that of seawater, and hence the mine water body is unlikely to have an adverse impact on the Anglesea River. • Water volumes in the event of a 1:100 type rainfall event that resulted in any possible mine water body overflow into the Anglesea River would preclude any measurable impact on environmental values.	• No adverse impact on Anglesea River environmental values. NOTE: - Historical Anglesea River water quality precludes most environmental values which is complimentary with background surface waters including Anglesea River and Salt Creek. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 - Waters. NOTE: - the mine water body lies entirely within the disturbed and controlled area and will not interact with any area outside the boundary of the licensed mining area during water body filling.	Insignificant	Insignificant	Insignificant	Rare	Low	• Six-Monthly mine water body water quality sampling • Six-Monthly groundwater water quality sampling at MB UEVF and DBG bores. • Mine water body water level and Bureau of Meteorology (BOM) rainfall monitoring. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
2.1	Groundwater quality	• CLA interaction with groundwater adversely impacts DBF/ASA groundwater quality in the undisturbed DBF/ASA aquifers during filling.	• DBF • ASA	• Refer to control measures in Element 1.1 above. • Leached ash particle migration not expected to extend beyond the licensed mine boundary. (Refer to Consolidated Leached Ash Technical Assessment, EHS Support (2023) Section 9 showing maximum particle movement of 49 m away from the water body over 200 years during fast fill scenario). • Direct discharge of ash pore water into the water body is unlikely as maximum particle movement occurs away from the water body during filling and negligible movement towards the water body after filling. • Undisturbed DBF approx. 400 m (east) of consolidated leached ash material. • DBG water quality monitoring and potential modification of WB16 extraction rates during filling (if required) to adjust the phreatic surface gradient into formation dependent on water quality monitoring results and pressures. • ASA overlies the DBF deposits and associated with the Lower Anglesea River system and is located at least 400 m away.	• No adverse impact on undisturbed DBF/ASA water quality measured by no exceedance of the adopted screening criteria for Water Quality Performance Targets as discussed in Section 4 Consolidated Leached Ash Technical Assessment, EHS Support (2023), applicable in accordance with the environment values to be protected under Segment B groundwater. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters. • Potential for elevated calcium however there are no ANZECC criteria for this constituent (refer to Table 6-8).	Insignificant	Insignificant	Minor	Unlikely	Low	• Six monthly mine water body water quality sampling. • Six monthly groundwater water quality sampling at MB UEVF and DBG and ASA bores. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
2.2	Groundwater quality	• CLA interaction with groundwater adversely impacts UEVF groundwater quality in the underlying UEVF (upper sands) aquifer during filling.	• UEVF	• Refer to control measures in Element 1.1 above. • Leached ash particle migration not expected to extend beyond the licensed mine boundary. (Refer to Consolidated Leached Ash Technical Assessment, EHS Support (2023) Section 9 showing maximum particle movement of 49 m over 200 years during fast fill scenario). • UEVF separation via basal clay and multiple low permeability layers therefore there is no perceived pathway between the CLA area and the UEVF below the basal clay. • UEVF water quality monitoring and modification of WB16 extraction rates during filling (if required) to reduce potential UEVF leakage into formation dependent on water quality monitoring results and pressures. • Upward hydraulic gradient currently exists between underlying UEVF (upper sands) and mine pit.	• No adverse impact on UEVF water quality measured by no exceedance of the adopted screening criteria for Water Quality Performance Targets as discussed in Section 4 Consolidated Leached Ash Technical Assessment, EHS Support (2023)in accordance with the environmental values to be protected under Segment B groundwater. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters.	Insignificant	Insignificant	Minor	Rare	Low	• Six monthly mine water body water quality sampling. • Six monthly groundwater water quality sampling at MB UEVF and DBG bores. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.

						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
2.3	Groundwater quality	• CLA with groundwater (DBF/UEVF/ASA) adversely impacts third party users during filling.	• UEVF aquifer domestic users. • LEVF Barwon Water. NOTE there are no third-party users for DBF/ASA.	• Refer to control measures in Element 1.1 above. • Two nearest domestic users are located 3 km southeast and8.5 km northeast of the mine. • No authorised or unauthorised domestic users could be located within 400 m of the CLA due to the extent of the Alcoa mine and land management area. • UEVF sits above the LEVF separated via the MEVF (aquitard). General upward gradient from the LEVF. • Leached ash particle migration not expected to extend beyond the licenced mine boundary. (Refer to Consolidated Leached Ash Technical Assessment, EHS Support (2023) Section 9 showing maximum particle movement of 49 m over 200 years during fast fill scenario). • Direct discharge of ash pore water into the water body is unlikely as maximum particle movement occurs away from the water body during filling and negligible movement towards the water body after filling • Decommissioning of historical redundant power station bores where required. • No UEVF/LEVF interactions observed by Alcoa or Barwon Water during 2021 and 2022 pumping tests.	• No adverse impact on LEVF/UEVF third party water users. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters.	Insignificant	Insignificant	Major	Rare	Medium	• Six monthly mine water body water quality sampling. • Six monthly groundwater water quality sampling at MB UEVF and DBG and ASA bores. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.
2.4	Groundwater quality	• CLA with groundwater (DBF/UEVF) adversely impacts GDE's during filling.	• GDE's Flora and Fauna	• Refer to Control Measures in Element 3 and Element 4. • Interim WQPTs for the mine water body water quality complimentary to existing background surface water quality which the native flora and fauna are adapted to. • No known GDE's in the pathway of the modelled groundwater flow direction.	• No adverse impact on GDE's native flora and fauna. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters.	Insignificant	Insignificant	Minor	Rare	Low	• Six monthly mine water body water quality sampling. • Six monthly groundwater water quality sampling at MB UEVF and DBG bores. • Reporting via monthly ERR report and via Community Consultative Network meetings or regular updates. • Health and Safety and Environmental Incident reporting.

						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
3.1	Erosion & Sedimentation	• Surface water run off (rain fall) reducing cover material to below 0.7m depth before being submerged. • Water body level increase eroding cover material to below 0.7m depth at shoreline interface.	• Mine Water body	• >1 m clay rich cover material with lab sampled permeabilities of less than 1x10-9m/sec. • Leached ash particle migration not expected to extend beyond the licensed mine boundary. (Refer to Consolidated Leached Ash Technical Assessment, EHS Support (2023) Section 9 showing maximum particle movement of 49 m over 200 years during fast fill scenario). then it would take approximately 2.8 years for a particle to move through 0.7 m of cover material. • Erosion trigger of 0.7 m set considerate of this. • Direct discharge of ash pore water into the water body is unlikely as maximum particle movement occurs away from the water body during filling and negligible movement towards the water body after filling. • Cover material surface area grade approx. 1:50 minimising surface water and 'shoreline' erosion, with site observations of similar grade shorelines showing minimal shoreline erosion. • Steeper 'shoreline' sections (west end and north side) material cover approximately 6m thick due to haul road and embankment construction, with site observations of steeper grade shorelines showing localised erosion of approximately 0.3 m. • Dispersivity testing of CLA material and surrounding fill material suggests risk of soil dispersion is low. • Implement monthly inspection program and repair strategy (TARP) for any surface water or shoreline erosion features to maintain cover.	• No adverse impact on mine water body water quality measured by no exceedance of 10th or 90th percentile of interim WQPT's. • No active erosion rill lines in surface cover material resulting in consolidated leached ash cover <0.7 m. • No shoreline erosion of cover material resulting in consolidated leached ash cover <0.7 m. • No aesthetic issue created by erosion of ash into the water body and creating a cloud of silty water. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters. NOTE: the mine water body lies entirely within the disturbed and controlled area.	Insignificant	Insignificant	Minor	Possible	Medium	• Monthly inspection of covered ash surface area for rill presence/activity using accepted visual criteria for activity recording or rill location and dimensions. • TARP for Inspect and repair program for any erosion features with trigger for erosion >0.3m cover depth until consolidated leached ash material fully submerged. • Monthly consolidated leached ash shoreline interface area erosion/slumping inspection for unacceptable erosion (>0.3mm). • Six monthly mine water body water quality sampling. • Establish a baseline LiDAR survey for CLA area, and investigate ongoing topographic survey methods including both LiDAR and/or using a single or multibeam echo sounding methodology to measure CLA surface during filling. • Reporting via monthly ERR report and bimonthly Community Consultative Network meetings. • Health and Safety and Environmental Incident reporting.

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
3.2	Erosion & Sedimentation	• Differential settlement of area during submersion resulting in cover material to below 0.7m depth. • Erosion of submerged cover material to below 0.7m depth.	• Mine Water body	• Refer to control measures in Element 3.1 above. • No Salt Creek inlet or Anglesea River discharge so no flows or currents through the water body. • No planned active recreational use so no powerboats and no associated water disturbance or mixing. • Ongoing silting expected during the filling period due to water and material run off from unsubmerged 1:3 slopes. Expected (as observed experientially since 2016) additional silt material settlement on top of the existing area further protecting the cover material. • Long term covered ash area estimated to be more than 12 m below the future surface level of the mine water body limiting any surface flows/current impacts on the covering. • Geotechnical Designs submitted as part of the Work Plan Variation – Progressive Rehabilitation Works approved by ERR March 2018 demonstrating safe and stable nature of the area. • No differential settlement observed in this area since consolidation and covering in 2017/2018.	• No adverse impact on mine water body water quality measured by no exceedance of 10th or 90th percentile of interim WQPT's. • No active erosion rill lines in surface cover material resulting in ash cover <0.7 m. • No shoreline erosion of cover material resulting in ash cover <0.7m. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters. NOTE: the mine water body lies entirely within the disturbed and controlled mine area.	Insignificant	Insignificant	Minor	Rare	Low	• Monthly inspection of covered ash unsubmerged surface area for potential settlement/surface cracking/etc during filling. • Annual LIDAR survey of covered ash unsubmerged surface area to measure for potential differential settlement. • Six monthly mine water body water quality sampling. • Reporting via Monthly ERR report and bimonthly Community Consultative Network meetings. • Health and Safety and Environmental Incident Reporting.

Element	Mining Hazard	Potential Risk Source (incl activity or circumstance)	Potential Receptors at Risk	Control Measures (Physical and Administrative)	Performance Objective, Standard, OR Criteria for Each Control OR Combination of Control Measures	Consequence			Likelihood	Risk Rating	Monitoring and Reporting
						Public Safety	Community Facilities, Including Property, and Infrastructure	Land and Environment			
3.3	Erosion & Sedimentation	• Disturbance of clay-rich cover material after submergence to below 0.7m depth • Bioturbation of clay-rich cover surface by benthic fauna	• Mine Water body	• Refer to control measures in Element 3.1 above. • Reference to limnological research of acidic pit lakes, indicate that when the CLA area is completely submerged (to approximately 12 m depth) the presence of benthic fauna within the sub-surface of the clay-rich cover will be controlled by the availability of carbon sources, i.e., organic material. Literature suggests that benthic fauna are restricted to areas where aquatic plants are present and more diverse ecosystems can develop due to shelter and direct or indirect food sources. Benthic macrofauna development is also limited by the acidic environment (e.g., prevents shell development in molluscs) and soft bodied fauna are susceptible to epidermis coagulation due to the sulfuric acid. Negligible dissolved oxygen concentrations at depth also limit the presence of benthic fauna. • Post submergence, bathymetric surveillance will be conducted to monitor the elevation and stability of the CLA area. • With no connection to surrounding surface water systems the input of nutrients (carbon, nitrogen, and phosphorus) will be extremely low and biological development within the mine water body is unlikely. • Based on the literature research it is concluded that the potential for the presence of benthic fauna is very low and the risk of bioturbation is also very low. • (Harp and Hubbard, 1972; Rodriques, 2001; Lagauzere et al, 2010; and Lund et al, 2020).	• No adverse impact on mine water body water quality measured by no exceedance of 10th or 90th percentile of interim WQPT's. • No active erosion rill lines in surface cover material resulting in ash cover <0.7 m. • No shoreline erosion of cover material resulting in ash cover <0.7 m. • Compliance with EPA Act 2017 Environmental Reference Standard Part 5 – Waters. NOTE: the mine water body lies entirely within the disturbed and controlled mine area.	Insignificant	Insignificant	Minor	Rare	Low	• Monthly consolidated leached ash shoreline interface area erosion/slumping inspection for unacceptable erosion (>0.3mm). • Six monthly mine water body water quality sampling. • Establish a baseline LiDAR survey for CLA area and investigate ongoing topographic survey methods including both LiDAR and/or using a single or multibeam echo sounding methodology to measure CLA surface during filling. • Reporting via monthly ERR report and bimonthly Community Consultative Network meetings. • Health and Safety and Environmental Incident reporting.

10.5 Monitoring and Reporting

In addition to an awareness of the potential mining hazards and risks, the proposed control measures, and the associated performance objectives for each combination of control measures, Alcoa has also identified appropriate monitoring tools and programs to measure performance against the specified objectives and methods for reporting on performance against the specified objective.

The monitoring and reporting tools are consistent with those used for similar works at Anglesea under the currently endorsed Work Plan (September 2011) and Work Plan Variation – Progressive Rehabilitation Works (March 2018). The proposed monitoring and reporting tools, processes, and methods for each combination of control measures are shown in **Table 10-6** and include:

- Six monthly mine water body water quality sampling;
- Six monthly groundwater water quality sampling at MB UEVF and DBG and ASA bores;
- Monthly inspection of covered consolidated leached ash surface area for rill presence/activity using accepted visual criteria for activity recording or rill location and dimensions;
- Monthly covered consolidated leached ash shoreline interface area erosion/slumping inspection for unacceptable erosion (>300mm);
- Monthly inspection of covered ash unsubmerged surface area for potential settlement/surface cracking/etc. during filling;
- TARP for inspection and repair program for any erosion features with trigger for erosion >0.3m cover depth until consolidated leached ash area is fully submerged;
- Annual LIDAR survey of covered ash unsubmerged surface area to measure for potential differential settlement;
- Development of a post submergence plan which will include bathymetric surveillance to monitor the elevation and stability of the CLA area;
- Health and Safety and Environmental Incident reporting; and
- Reporting via monthly ERR report.

A key reporting tool is expected to continue to be the monthly ERR report, a process that currently exists and is expected to continue to be refined in consultation with the ERR to ensure that it is efficient, effective, and meets the needs of both ERR and Alcoa.

It is expected that the specific consolidated leached ash area data, report format and WQPT collected as part of the above monitoring events and inspections will be included appropriately in the monthly report.

11 Summary and Conclusions

The objective of this review was to complete a detailed technical review and risk assessment for the activity of submerging the CLA material covered by at least 1 m of low permeability clay-rich overburden in order to understand any associated short and long-term risks to the environment.

The aim of the assessment, including the numerical modelling, was to test the hypothesis:

> *'The submergence of the encapsulated consolidated leached ash will not result in adverse risk of harm to human health or the environment within the catchment.'*

Based on the summary and conclusions below, this hypothesis has been confirmed.

This review also provides a detailed technical response to the feedback received from ERR (and EPA) in the letter to Alcoa dated 29 November 2017, and also on the items detailed by the EPA in the letter to Alcoa dated 20 October 2021.

The technical review has included:

- A review of CCA and leached ash characterisation and management at the former power station and open cut brown coal lignite mine at Anglesea.
- Extensive field investigations, sampling, and laboratory analysis of the materials in and around the CLA area located within the south-east corner of the mine.
- Development of a bespoke numerical hydraulic model to simulate water fluxes in and around the CLA related to both surface water and groundwater changes over time, inclusive of particle movement and tracking.
- A literature review of ash management and characterisation at national and international facilities and the evaluation of best available techniques and technologies.
- Completion of a detailed risk assessment related to both surface water and groundwater risks to the environment.
- Completion of an independent peer review of the key elements above and this final report, by BlueSphere.

Historically CCA has been produced and managed at the former Anglesea power station and was temporarily stored and leached in Ash Pond 1 before being dried and deposited in the former open cut pit as leached ash. The leached ash was then historically placed into the former open cut coal mine in accordance with the Mine Work Plan endorsed by ERR in September 2011.

Interim WQPTs have been developed and are included within this assessment (**Section 4**). Final WQPTs, are expected to be included as part of the MRCP (when finalised).

More recently following mine closure, in early 2018 the existing leached ash in the south-east corner of the former mine was consolidated into a small footprint between RL -15 m and RL -8 m and clay-rich material was then used to cover the CLA to a minimum 1 m thickness. The CLA is also bounded by clay-rich material from the west (clockwise) around to the north-east, by the berm and haul road respectively. Unconsolidated fill material (silts, clays, and minor sands) underlies and surrounds the CLA from the north-east (clockwise) to the west (**Section 5**).

There have been two phases of field investigations within the CLA area in 2021 and 2022. The objectives of the field investigation were to collect multiple samples for the measurement of permeability and chemical characterisation of materials encountered within and surrounding the consolidated leached ash. The outcome of both phases of investigation have confirmed that low permeability materials (less that $1x10^{-9}$ m/sec) were consistently encountered both within and surrounding the CLA area and to a minimum thickness of 1 m of clay-rich cover overlying the CLA. Chemical characterisation and comparison between CLA and surrounding fill material show that constituents indicative of and at a magnitude representative of leached ash, are only encountered within the CLA area (**Section 6** and **Section 7**).

The following chemical and physical controls were noted from the literature review (Section 8) to influence and limit the mobility of major and minor ion constituents from CCA porewater to groundwater:

1. Leaching and aging of CCA in ash ponds for at least one year, enables the dissolution of more soluble constituents from the CCA into the pond water to produce leached ash.
2. Drying of leached ash occurred prior to deposition or consolidation and draining to lower the moisture content so leached ash could be tracked with earth moving machines to produce CLA.
3. Surrounding the CLA with low permeability clay-rich material.
4. Settling of fines within the CLA creating low permeability horizons.
5. Alkaline porewater within the leached ash limits the solubility and mobility of minor ions.
6. Sulfate can be attenuated by SRB providing electron donors are present, e.g., labile organic carbon.

These management controls have been demonstrated to have been used by Alcoa and chemical characterisation has demonstrated that leaching of CCA has produced a leached ash with a significantly lower leachable fraction of major and minor ion constituents.

A numerical model was developed using GeoStudio SEEP/W software simulating the hydraulic behaviour of rising water body and groundwater levels and potential groundwater seepage into the fill material under steady-state and transient conditions; and included particle tracking to observe movement of particles representative of a conservative (not subject to attenuation or retardation) constituent within the model domain. The model was run under various scenarios including natural water body filling (46 years), fast filling (10 years), and under a rapid fill type- event (less than 1 year).

The modelling showed that under all simulated scenarios (natural and fast fill) the water body evolves as a groundwater sink. In the fast fill scenario (where supplementary water is used to fill the mine pit), maximum particle movement is 41 m in 200 years and groundwater flows away from the water body for less than 20 years. Under sensitivity analysis particles did migrate further that 46 m however, not to distances that indicate receptor impacts. These distances are significantly less than the distance to the edge of the mine disturbed area of approximately 400 m; overall, the modelling results clearly indicate that the low permeability characteristics of the CLA, the 1 m clay rich cover material, and the surrounding materials are highly effective in reducing the advective flux of particles placed within the CLA during any future inundation scenario in both the short and long term.

Finally, a simple mass balance calculation using the leachable mass of selected constituents in CLA and the water body quality was used to assess current and future water body quality if the CLA was mixed into the water body. The resulting concentrations of aluminium, boron, iron, manganese, and zinc would be most likely be within the range of expected concentrations and with limited increase in risk to environmental values. (**Section 9**).

A detailed risk assessment (**Section 10**) was completed in accordance with Part 3 Division 6 Section 44 of the Mineral Resources Sustainable Development (Mineral Industries) Regulations 2019 assessing risks associated with submerging the CLA material located in the south-east corner of the mine. The process and framework is consistent with those outlined in 'Preparation of Work Plans and Work Plan Variations GUIDELINE FOR MINING PROJECTS' **Appendix B** (December 2020 version 1.3) provided by the Department of Jobs Precincts and Regions. The risk assessment considered all elements outlined in the various sections of this technical assessment, including the water quality performance targets for both surface water and groundwater (**Section 4**).

The risk assessment did not identify any high risks, with only two medium risks identified and all remaining risks identified as low. The main risk mitigation measure adopted by Alcoa is the encapsulation of the CLA in a low permeability material, on average less than 1x10-9 m/sec. The medium risks are considered to be conservatively assessed and are related to third party users (albeit with the lowest likelihood rating of 'Rare') and potential for erosion of the covering material. Appropriate performance criteria, counter measures and monitoring criteria have been identified for ongoing monitoring and management of the risks into the future.

It should be noted that leachable fraction analysis of the CLA demonstrates that ash pore water is unlikely to have any measurable environmental impacts in either groundwater or the water body.

In addition to the technical assessment work completed by Alcoa described above, BlueSphere were engaged to conduct an independent peer review of the entire technical assessment and all of its key elements. The independent peer review identified a number of improvement opportunities during the process which have been actioned and included as part of this final technical assessment, significantly improving the level of confidence in the conclusions reached. The independent peer review concluded that:

- The combined assessment and characterisation work on the physical properties of the CLA is considered to have been completed in accordance with appropriate and relevant legislation, guidance, and industry standards to the extent practicable. The outcomes of this work are considered to be a reasonable basis from which to assess the likely future impacts on the surrounding environment from the submergence of the CLA within the pit lake.
- Numerical modelling has been utilised to make predictions regarding the future environmental performance of the CLA cap and other encapsulating materials. The model is considered to be sufficiently rigorous given the setting, margin of safety indicated by the modelling results, and relatively modest modelling objectives.
- The numerical modelling, together with other lines of evidence including the site-specific physical characterisation of the materials, has been used to inform the risk assessment process. The risk assessment concludes that the activity of submerging the CLA beneath the pit lake represents a low risk of adverse environmental outcomes in both the short and long term.
- In the context of the specific assumptions (**Section 4.1**), the history of regulation and the environmental setting, the ITPR team is of the view that the submergence of the CLA does present a low risk of adverse environmental outcomes for surface water and groundwater and that the approach is consistent with previous regulatory directions and broader principles of environmental protection, including the GED.

- Future monitoring and verification of the environmental performance is considered to be a key tenet of sound environmental management. The CLARA provides the overall monitoring principles which the ITPR team considers appropriate. It is understood that specific detail on the future monitoring requirements, trigger levels and contingency actions are to be prepared prior to the submergence of the CLA. The ITPR team emphasises that an appropriately detailed water management plan as proposed should be developed and implemented so as to provide a robust framework for future environmental management of the CLA.

Refer to **Appendix A** for IPR letter.

In conclusion, this Consolidated Leached Ash Technical Assessment provides the technical information supporting the Alcoa proposal to submerge the CLA material covered by at least 1 m of low permeability clay-rich fill material, meeting Alcoa's GED. This demonstrates that risks to the environment (including surface water and/or groundwater) remain low as far as reasonably practical in both the short and long term regardless of the water body fill strategy.

Notes
Modified ASLP test was undertaken on a split replicate sample (PTH-16-0045) of PTH-16-0042 (EM1607137-006), Ash Pond 1 location 1 S bank.
One reagent water was a replicate ashpond water sample (PTH-16-0040) of PTH-16-0039 (), Ash Pond 1 location 3 NE bank.
For original analysis of replicate samples refer to PTH-16-0039 (ash pond water) and PTH-16-0042 (ash solid)

Table Notes:

m bgl: metres below ground level

t/m3: metric tonnes per cubic metre

(m/sec): metres per second

Table 11
Emerson Results

Sample	Emerson Class Number	Observations
ANG-21-0189	4	The remoulded soil does not disperse in water. Calcium carbonate (calcite) or calcium sulfate (gypsum) is present.
ANG-21-0193	4	
ANG-21-0195	4	
ANG-21-0196	4	
ANG-21-0197	4	
ANG-21-0200	4	
ANG-21-0207	4	
ANG-21-0211	4	
ANG-21-0191	2	Air-dried crumbs of soil show a moderate to slight reaction. A moderate reaction consists of an easily recognizable cloud of colloids in suspension, usually spreading in thin streaks on the bottom of the beaker. A slight reaction consists of the bare hint of cloud in water at the surface of the crumbs.
ANG-21-0201	2	
ANG-21-0202	2

Table 14
Geotechnical Results - Saline Water (5,000 ppm NaCl)

Sample ID	Depth (m bgl)	Lithology- Field	Lithology - Laboratory	Classification	Plasticity	Material Type	Moisture Content (%)	Dry Density (t/m3)	Hydraulic Conductivity (m/sec)
ANG-22-0015	0-0.5	Fine to coarse grained, pale brown, firm, moist, with clay - low plasticity, firm, moist	clayey SAND,fine to coarse, brown, trace gravel	Clayey SAND	L	Clay rich layer	8.3	1.9	7.00E-08
ANG-22-0016	0.5-1	Fine to coarse grained, pale brown, firm, moist, with clay - low plasticity, firm, moist	silty CLAY, medium plasticity, mottled brown, grey, black	Clayey SAND	M	Clay rich layer	18.9	1.69	1.00E-09
ANG-22-0019	0.5-1	Fine to coarse grained, dark brown, firm, moist, with interstitial clay - medium plasticity, pale grey to dark brown.	sandy silty CLAY, low to medium plasticity, mottled brown, grey, black, white	Silty SAND	M	Clay rich layer	20.5	1.69	1.00E-09
ANG-22-0022	0-0.5	Fine to coarse grained, brown to dark brown, loose, slightly moist, medium plasticity clay, grey to brown.	sandy CLAY, low to medium plasticity, brown, trace gravel	Clayey SAND	M	Clay rich layer	9.9	1.89	4.00E-10
ANG-22-0023	0.5-1	Fine to coarse grained, brown to dark brown, loose, slightly moist, medium plasticity clay, grey to brown.	CLAY, low to medium plasticity, dark brown	Clayey SAND	M	Clay rich layer	20.1	1.71	2.00E-10
Min							8.3	1.69	2.00E-10
Max							20.5	1.90	7.00E-08
Average (geomean)							14.5	1.77	1.41E-09
Standard Deviation							5.9	0.11	3.10E-08
ANG-22-0017	5-5.5	Medium plasticity, soft, moist, becomes mottled orange, red and dark brown, with interstitial coal	silty CLAY, low to medium plasticity, mottled brown, grey, black, yellow, with sand	Silty CLAY	M	Fill material	38.3	1.48	2.00E-10
ANG-22-0018	5.5-6	Medium plasticity, soft, moist, becomes mottled orange, red and dark brown, with interstitial coal	silty CLAY, medium plasticity, brown, trace sand	Silty CLAY	M	Fill material	62.8	0.93	5.00E-09
ANG-22-0020	5-5.5	Fine to coarse grained, orange, well sorted, medium plasticity clay, soft, moist	sandy CLAY, low to medium plasticity, brown	Clayey SAND	M	Fill material	14.9	1.8	9.00E-09
ANG-22-0021	5.5-6	Fine to coarse grained, orange, well sorted, medium plasticity clay, soft, moist	sandy CLAY, low to medium plasticity, brown	Clayey SAND	M	Fill material	13.1	1.85	1.00E-08
ANG-22-0024	5-5.5	Medium plasticity, grey, moist to wet, very soft, with no gravel and interstitial coal	silty CLAY, medium to high plasticity, brown, trace gravel, trace sand	Sandy CLAY	M	Fill material	35.7	1.34	7.00E-10
ANG-22-0025	0-2	Fine to coarse grained, dark brown to black, loose, slightly moist, with some quartz gravels, subrounded to 8 mm and low plasticity clay	silty sandy CLAY, medium plasticity, brown, trace gravel	Clayey SAND	M	Fill material	14.8	1.83	3.00E-10
ANG-22-0027	4-6	Fine grained, yellow to orange, loose, moist, with some medium plasticity clay and rounded gravels to 25 mm	sandy CLAY, medium to high plasticity, brown	Silty SAND	M	Fill material	8.7	1.92	3.00E-09
ANG-22-0029	0-2	Fine to coarse grained, orange to red, loose, moist, with low plasticity clay and some quartz gravels, rounded to 5 mm	silty CLAY, medium plasticity, mottled brown, yellow, with sand, trace gravel	Clayey SAND	L	Fill material	12.1	1.76	4.00E-08
ANG-22-0030	2-4	Medium plasticity, dark grey/black to brown, slightly firm, moist, with coal	No saline test result - sample collapse between solutions	Sandy CLAY	M	Fill material	-	-	-
ANG-22-0032	2-4	High plasticity, brown to grey with black, fine to coarse grained sand	silty sandy CLAY, medium to high plasticity, brown, with gravel	Sandy CLAY	H	Fill material	13.9	1.85	5.00E-10
ANG-22-0034	4-6	Medium plasticity, dark grey/black to brown with traces of red, slightly firm, moist, with coal	clayey SAND, fine to coarse, brown, fines of low to medium plasticity	Sandy CLAY	M	Fill material	13.1	1.79	2.00E-10
ANG-22-0035	0-2	High plasticity, black to orange, soft, moist, with trace angular gravels to 10 mm	silty SAND, fine to coarse, black	Silty CLAY	H	Fill material	30.1	1.13	9.00E-09
ANG-22-0037	4-6	High plasticity, grey, black and red, soft, moist, with trace wood fragments and angular gravels to 10 mm	silty CLAY, high plasticity, mottled brown, dark grey, trace sand	Silty CLAY	H	Fill material	21.5	1.72	1.00E-09
ANG-22-0039	0-2	Fine to coarse grained, pale brown, soft/loose, moist, with some rounded quartz gravels to 8 mm.	silty CLAY, medium to high plasticity, brown, trace gravel, trace sand	Silty SAND	M/H	Fill material	56	1.04	1.00E-09
ANG-22-0040	2-4	Medium plasticity, dark brown/grey, soft, wet, with trace orange/red mottling	clayey SILT, medium plasticity, brown	Sandy CLAY	M	Fill material	52.4	0.96	2.00E-09
ANG-22-0042	2-4	Fine to coarse grained, pale brown to brown, moist, with trace quartz gravels	silty CLAY,medium-high plasticity, dark brown, trace gravel	Clayey SAND	M/L	Fill material	71.9	0.91	2.00E-09
ANG-22-0044	4-6	Fine to coarse grained, pale brown, loose, wet, with some rounded quartz gravels to 6 mm.	silty CLAY, medium plasticity, grey, with sand	Silty SAND	M	Fill material	24.1	1.6	7.00E-10
ANG-22-0045	0-2	Medium plasticity, dark brown to brown and grey, soft to slightly firm, moist, with fine grained sand. Coal and silty clay: high plasticity, grey, soft	silty CLAY, medium to high plasticity, brown	Sandy CLAY	M/H	Fill material	18.5	1.71	8.00E-11
ANG-22-0047	2-4	Medium plasticity, dark brown to orange, with increasing fine sand content, moist. Coal and silty clay: high plasticity, grey, soft.	sandy CLAY,medium to high plasticity, brown, trace gravel	Sandy CLAY	M/H	Fill material	15.5	1.81	4.00E-10
ANG-22-0048	4-6	Medium to high plasticity, grey to brown, very soft, moist to slightly wet	silty CLAY, medium plasticity, brown, trace gravel	Sandy CLAY	M	Fill material	31.2	1.51	2.00E-10
ANG-22-0049	2-4	High plasticity,light brown to grey, soft to slightly firm, moist to slightly wet, very fine silt, with trace coal	clayey SILT, low to medium plasticity, brown, with sand	Silty CLAY	M	Fill material	64.2	0.82	3.00E-08
ANG-22-0051	4-6	Fine to coarse grained, dark brown to orange and grey, loose and soft, clay: medium plasticity, with some coal and gravel.	sandy CLAY, low to medium plasticity, dark brown, trace gravel	Clayey SAND	M	Fill material	18.1	1.74	3.00E-10
Min							8.7	0.82	8.00E-11
Max							71.9	1.92	4.00E-08
Average (geomean)							24.6	1.45	1.32E-09

Appendix A Independent Peer Review Letter

BlueSphere Environmental Pty Ltd
113 Ferrars Street
Southbank VIC 3006

19 June 2023

Warren Sharp
Alcoa of Australia Limited
Alcoa Anglesea
Camp Road,
Anglesea, VIC 3230

Dear Warren,

Re: Independent Technical Peer Review of the Consolidated Leached Ash Technical Risk Assessment, Alcoa Anglesea Mine

1 Introduction

BlueSphere Environmental Pty Ltd (BlueSphere) was engaged by Alcoa of Australia Limited (Alcoa) to provide independent technical peer review (ITPR) services in relation to the characterisation and risk assessment of a consolidated leached ash deposit within the mine void of the former Anglesea coal mine. The characterisation and risk assessment work has been conducted by environmental consultants EHS Support Pty Ltd (EHS Support), who is also engaged by Alcoa.

Specifically, the review was to consider the potential environmental impacts associated with the activity of submerging the consolidated leached ash (CLA), its cap and other encapsulating materials, beneath the future pit lake from a technical perspective.

2 Background

Alcoa operated a coal mine and power station at Anglesea from 1969 to 2015, with decommissioning, rehabilitation and closure activities having been ongoing since that time. In 2017, Alcoa developed a draft Mine Closure and Rehabilitation Plan (MCRP), to ensure that the rehabilitation would provide a safe, stable and sustainable landform that compliments the surrounding natural environment. Key elements of the MCRP included development of a pit lake, extensive rehabilitated and revegetated areas and some areas of future alternative land uses. The MCRP was submitted to Earth Resources Regulation (ERR) in late 2017.

In accordance with the MCRP, and as part of the ERR approval of the cover and overburden backfilling strategy, leached ash from two former ash ponds was deposited and consolidated in the south eastern corner of the mine void and covered with a semi-engineered clay cap. The CLA occupies an area of approximately seven (7) hectares, with an average depth of 4 metres, within a mine void covering approximately 100 hectares.

The ERR approval included a requirement for the further consideration of the potential environmental impacts of the CLA in Alcoa's final MCRP. Furthermore, in 2021, EPA Victoria (EPA), advised Alcoa that approval for the landfill cap was required through a licence surrender process, the application for which would require the provision of detailed technical information in relation to the landfill cap, including an ITPR.

These further technical studies were conducted between 2017 and September 2022 by EHS Support and the findings consolidated in the Consolidated Leached Ash Technical Risk Assessment (CLARA) report (EHS Support 2023). The CLARA is the primary document subject to review by the ITPR team.

3 Objectives

The objectives of the ITPR are as follows:

- Provide an independent opinion on the technical veracity of the works completed by Alcoa (and its consultants) in ensuring an environmentally sound outcome in relation to the submergence of the consolidated leached ash deposit; and

- Provide advice regarding the technical aspects of the assessment process to help ensure a robust outcome that is consistent with relevant environmental legislation and guidance.

4 Scope and Methodology

4.1 Basis and Scope of Review

The review conducted by the ITPR team was limited to the potential environmental impacts associated with the CLA under a specific scenario whereby it was submerged within the developing pit lake.

The review relies on a number of specific assumptions to constrain the predictions regarding likely future environmental outcomes. These assumptions include:

- That the consolidated leached ash remains a geotechnically stable landform, with the integrity of the encapsulating materials remaining fundamentally unchanged from present day conditions;
- That the consolidated leached ash is submerged within the pit lake at a depth of approximately 12 m;
- That the pit lake acts as a terminal discharge feature once established, with a surplus of evaporation over inputs of rainfall, runoff and groundwater ingress, and that there is no surface water connectivity between the pit lake and surrounding catchment.

The review scope comprised four key components:

1) Review of the conceptualisation of the consolidated leached ash deposit and the further physical characterisation of the ash and encapsulating materials;
2) Review of the hydrogeological modelling, including model selection, parameterisation, predictions and sensitivity analysis;
3) Review of the consolidated leached technical ash risk assessment; and
4) Review of proposed water quality performance standards and monitoring for the pit lake in so far as they relate to any future impacts on water quality deriving from the CLA.

The review work considers only information relevant to, and the potential outcomes of, the activity of submerging the CLA within the pit lake water body; it does not consider potential broader water quality issues within the pit lake water body. It is understood that these matters have been, or will be, addressed through separate limnological, geochemical and water balance studies as necessary as part of the MCRP.

The work completed by BlueSphere does not constitute a statutory Environmental Audit as defined under the *Environment Protection Act 2017* and BlueSphere did not act in the role of an EPA-appointed Auditor.

4.2 Regulatory Framework and Approach

The review was conducted in accordance with, or with reference to, the following Acts, regulations, guidelines and codes, to the extent that each was considered relevant to the review scope:

- ANZG 2018. Australian and New Zealand Guidelines for fresh and marine water quality. Australian and New Zealand Governments and Australian State and Territory Governments, Canberra, ACT, Australia.
- Barnett, B; Townley, L; Post, V; Evans, R; Hunt, R; Peeters, L; Richardson, S; Werner, A; Knapton, A; Boronkay, A. Australian groundwater modelling guidelines. National Water Commission, Canberra, June 2012.
- EPA Victoria 2022, *Hydrogeological Assessment (Groundwater Quality) Guidelines*, EPA Victoria Publication 668.1.
- EPA Victoria, 2015, Siting, design, operation and rehabilitation of landfills, Best Practice Environmental Management, Publication 788.3, August 2015.
- Government of Victoria, 2017, *Environment Protection Act 2017*, No. 51 of 2017, as amended January 2020;
- Government of Victoria, 2021, Environment Protection Regulations 2021, S.R No 47/2021;

- Government of Victoria, 2021, Environment Reference Standard, No. S 245, 26 May 2021;
- National Environment Protection Council (1999, 2013 revision), National Environment Protection (Assessment of Site Contamination) Measure (NEPM 2013).

4.3 Documents Reviewed

The following documents were reviewed by the ITPR team, with detailed commentary provided in a register, a copy of which is enclosed as **Attachment 1**:

- Primary Document (including draft iterations):
  - EHS Support, 2023. Consolidated Leached Ash Technical Risk Assessment. Anglesea Former Mine Pit, Anglesea, Victoria. Final, 24 May 2023
- Supporting Documents (including draft iterations), some of which were later consolidated into the primary document:
  - EHS Support, 2022. Ash Risk Assessment, Hydrogeological Modelling, Former Coal Mine, Anglesea, Victoria, 6 June 2022.
  - EHS Support, 2022. Memo, SAQP Data Gap Analysis – Consolidated Ash Risk Assessment
  - EHS Support, 2022. Memo, Ash Risk Assessment – Supplementary Field Sampling Results
  - EHS Support, 2022. Memo, Alcoa Anglesea Mine Water Body and Groundwater Water Quality Performance Standards
  - EHS Support 2022, *Ash Risk Assessment – Overview and Supporting Documents*, Memorandum, 2 February 2022, including the following attachments:
    - Attachment 1 Conceptual hydrogeological model report
    - Attachment 2 Waste discharge licence EM32162
    - Attachment 3 Operating Licence 11429
    - Attachment 4 Consolidated Ash TWG Update Jul 2021
    - Attachment 5 Ash Assessment Technical Appendix M Mine Closure and Rehabilitation Plan Sep 2017
    - Attachment 6 EPA letter October 2021 Approval pathway under new EP Act 2017.
  - EHS Support, 2021. Supplemental Surface Water and Soil investigation Report, Anglesea Alcoa Power Station, April 2021.

It should be noted that the ITPR team has not undertaken a comprehensive data validation (QA/QC) exercise to independently verify the accuracy, completeness and fitness for purpose of analytical results and other raw data sources. These data have been reviewed and utilised on an “as is” basis.

4.4 Site Inspection and Workshops

Members of the ITPR team (Dr Darren Bennetts and Dr Matt Edwards) conducted a Site inspection with representatives of Alcoa (Mr Warren Sharp, Ms Nicci Marris and Mr John Osborne) and EHS Support (Dr Rebecca Fraser and Mr Chris Smitt) on 28 March 2022.

The Site visit included a general Site overview, including history of mining operations, historical ash management practices and ongoing rehabilitation activities, followed by a walkover of the CLA area and inspection of the surficial encapsulating materials, including the cap, former haul road and berm area.

In addition to the Site visit, six formal meetings were conducted via teleconference or in person between the ITPR team, EHS Support and Alcoa on to discuss technical issues raised as part of the review. These meeting took place on the following dates:

- 31 May 2022;
- 15 September 2022;
- 7 October 2022;

- 12 January 2023;
- 8 May 2023; and
- 18 May 2023.

4.5 Independent Technical Peer Review Team

The members of the ITPR Team, role throughout the project, relevant qualifications, and fields of expertise, are summarised in **Table 1**.

Table 1 ITPR Team Roles and Capabilities

Reviewer	Role	Qualifications/Accreditations	Relevant field of expertise
Dr Darren Bennetts	Lead Reviewer	B.Sc (hons), Ph.D EPA Appointed Environmental Auditor (Contaminated Land)	Hydrogeology Contaminant Fate and Transport Environmental Chemistry Environmental Regulation
Dr Matt Edwards	Specialist Support – Geology and Hydrogeology	B.Sc (hons), Ph.D	Geology Hydrogeology
Dr Stuart Brown	Specialist Support – Groundwater Modelling	B.Sc (hons), M.Sc, Ph.D, MBA	Hydrogeology Groundwater Modelling
Darren Ellis	Internal Peer Review	B.Sc; M.Sc	Hydrogeology

5 Findings

The findings of the ITPR process have been structured with reference to the advice provided by EPA regarding the approval pathway for the ash landfill cap in its correspondence to Alcoa dated 21 September 2021. In this correspondence, EPA outlined the information that should be provided in order to facilitate the surrender of the ash landfill from EPA Operating Licence OL000011429. The ITPR team's opinions on how the CLARA responds to those items are addressed in turn in the following sections.

5.1 Detailed Design of the Landfill Cap

The design elements relevant to the clay-rich cover material placed over the CLA are detailed in Section 5.2.1 of the CLARA. As described by EHS Support the CLA was not intended to be designed as a traditional landfill and subsequently many of the requirements of the landfill BPEM are not considered to be applicable to the CLA. The CLA was deposited in the former mine pit and incorporated into the overburden backfill process, in accordance with the Mine Work Plan endorsed by ERR in 2011. The CLA will ultimately be submerged by the developing pit lake water body, as proposed by the draft Mine Closure and Rehabilitation Plan (MRCP). Rather for this application the landfill BPEM provides best practice guidance regarding specific design elements of the CLA such as cap and lining materials properties, performance objectives and construction quality assurance.

The CLA was placed between a portion of the sidewall of mine void to the east and south, a constructed haul road to the north and a constructed berm to the west, and underlain by pre-existing clay-rich overburden. Following emplacement a ≥ 1 m clay rich cover was placed over the CLA in a series of three lifts of approximately 0.35 m using clay-rich material derived from Demons Bluff Formation and Boonah Formation overburden, which were track rolled by bulldozer for compaction. The final cap was graded with a shallow gradient to the southwest to facilitate drainage.

As shown in Table 5-1 of the CLARA, this is considered to meet the relevant requirements for traditional landfill caps as per the BPEM, apart from lift thickness which was 350 mm as opposed to the BPEM which includes the suggested measure of placing clay in at least four to six lifts equating to a minimum lift thickness of 250 mm. It was also noted that the cap, sidewalls and base were not emplaced under CQA as per the BPEM, noting the CLA was not intended to be constructed or managed as a tradition landfill.

In view of the above, the emphasis has been on retrospectively confirming the physical properties of encapsulating materials such as the cap, adjacent berm and haul road and underlying and adjacent fill material. The outcome of these assessments is described in subsequent sections, but in summary the data collected generally describes a high degree of uniformity in physical properties, including low permeabilities equivalent to the partially engineered clay-rich cover, which in turn has permeability characteristics broadly consistent with the requirements from clay liners under the landfill BPEM. That is, whilst the construction elements of the BPEM were not always met, the performance outcomes in terms of material properties are indicated to have been met.

It is also noted that the permeability of the ash within the CLA was also assessed post-placement, with permeability values ranging from 2 x 10^{-10} to 9 x 10^{-9} m/s comparable to clay liner specifications (less than 1 x 10^{-9} m/s). This highlights that the rate of water movement through the CLA itself would be very low, which is in contrast to a traditional landfill which is often relatively porous.

5.2 Targeted Performance (short and long-term) and Outcomes of the Proposed Landfill Cap

The targeted performance and outcomes of the landfill cap includes providing an enduring physical separation of the leached ash and overlying water body when in contact with saline groundwater and CLA porewater, and to act as a long-term low permeability barrier reducing any dissolved contaminant flux from the CLA to the surrounding environment to acceptable levels.

Targeted performance includes maintenance of overlying water body and surrounding groundwater quality that is consistent with the current interim water quality performance targets, as defined in the CLARA, and in the fullness of time the final water quality performance targets developed as part of the final Mine Closure and Rehabilitation Plan (MCRP).

The ITPR team provided considerable feedback on the proposed interim WQPTs, which are based on the current water quality in the developing water body. In light of the following considerations the ITPR team concluded that the Interim WQPTs are an appropriate short-term benchmark:

- The proposed WQPTs are interim and that final WQPTs would be determined once a filling strategy has been confirmed;
- The Interim WQPTs are intended to relate only to localised impacts from the CLA on the water body and groundwater and not to broader pit lake water quality issues, with impacts from the CLA having been demonstrated through physical testing and modelling to present a low risk;
- Using the existing water body quality as the basis for the Interim WQPT will ensure there is no water quality deterioration beyond the existing conditions until such a time that the final filling strategy is resolved; and
- The proposed Interim WQPTs are consistent with natural background catchment water quality in most respects, with the exception of boron. If the final WQPTs proposed a boron target above catchment background, it would need to be subject to a quantitative site-specific ecological risk assessment to determine the appropriateness of the target. Maintaining consistency with natural background water quality is consistent with the requirements of the ERS.

Overall, the stated targeted performance and outcomes of the cap, as described in the CLARA are considered appropriate and consistent with prevailing environmental principles, including the General Environmental Duty (GED) to minimise risks to human health and the environment so far as reasonably practicable.

5.3 Information that Supports how the Proposed Cap is able to Achieve the Targeted Performance and Outcomes

The assessment program has provided information that supports how the proposed cap will achieve the targeted performance and outcomes in the following ways:

- Provision of information in relation the design, engineering (as relevant) and construction of the cap and the extent to which this complies with relevant best practice guidance (e.g. the landfill BPEM);
- Physical testing and laboratory analysis of parameters relevant to the performance of the cap, other encapsulating materials and the leached ash itself, such as permeability, dispersity and leachability testing;
- Numerical groundwater modelling, utilising the model inputs based on the above testing to predict future performance under a number of scenarios in which the CLA becomes submerged, including sensitivity analysis.

Overall, the information provided in the CLARA through these three lines of enquiry is considered to adequately demonstrate the likely performance of the cap and other encapsulating materials. The ITPR team raised a number of issues throughout the review process in relation to this item, including:

- The density of sampling and the appropriateness of the laboratory methods to replicate actual and predicted site conditions;
- Modelling assumptions, including that the CLA had no advective potential prior to being submerged, despite some of the ash deposit being placed as a slurry; and
- Long term cap integrity, including, but not limited to, the effects of wave action and bioturbation on the cap materials during and post lake establishment.

Throughout the review and consultation process, these issues were resolved through additional sampling and characterisation (**Section 5.4.1**), sensitivity analysis (**Section 5.4.2**) and commitments to the development of an appropriate monitoring and maintenance program (**Section 5.4.3**), respectively.

5.4 Monitoring Results Capable of Confirming that the Cap is Performing in line with Targeted Performance and Outcomes, short and long term

The CLA is currently sitting above the water level in the waterbody, such that the CLA, encapsulating materials and surrounding fill material are expected to be unsaturated. As the CLA has not yet been inundated, monitoring results confirming the caps performance have not yet been collected.

However, testing and analysis of construction materials followed by modelling has been utilised to predict performance during and post inundation, with a monitoring program proposed to verify performance once inundation occurs.

5.4.1 Testing and Analysis

The testing and analysis has focussed on the physical characteristics of the encapsulating materials and the chemical characteristics and behaviour of the leached ash under a range of conditions. These analyses are intended to inform future cap performance and have included the following in consultation with the ITPR team:

- Total major and minor ion analysis of the leached ash;
- Major and minor ion leachable fraction (Australian Standard Leaching Procedure) analysis of leached ash at two pH values, pH 2.9 and pH 7;
- Permeability testing of encapsulating material and surrounding fill material using both de-ionised water and saline water (5,000 ppm) permeameter methods;
- Dispersivity/Reactivity (Emerson Class Number) testing of the leached ash and surrounding material.

In reviewing these data, the ITPR team focussed on the representativeness and density of sampling, including with reference to relevant standards, and ensuring that testing methods were adopted to demonstrate material resilience to chemical conditions. The key outcomes of this review process was to request additional permeability sampling of cap and other encapsulating materials, so as to achieve a volume-based sampling density of 1:5,000 m^3, which accords with the clay characterisation guidance in the BPEM and the use of saline water in permeameter testing, so as to more accurately represent the water quality likely to inundate the CLA in future. Both of these recommendations were adopted by EHS Support and works completed in subsequent field testing programs. It is noted that

the BPEM recommends that the permeability of basal liners is tested with 50,000 ppm NaCl solution to reflect saline leachate that would be expected to be in contact with a basal liner in a conventional clay lined landfill; this was modified with agreement from the ITPR team to 5,000pmm given the clay will be in contact with lake water once submerged, not saline leachate.

The final dataset characterising the physical and chemical characteristics of the CLA and the expected future behaviour of the materials encapsulating the CLA is considered to be a suitably robust basis from which to make predictions about future cap performance.

5.4.2 Groundwater Modelling

Numerical groundwater (and surface water) modelling using the finite element modelling program SEEP/W was undertaken as the primary predictive tool for CLA environmental performance during and post inundation. The modelling objectives were to simulate the rising water body and groundwater levels in and around the CLA and undertake particle tracking of a conservative constituent within the CLA over time, to assess any potential impacts on the surrounding environment.

The ITPR review included consideration of the following:

- The appropriateness of the modelling software selection;
- Adherence to applicable guidelines (i.e. the Australian Groundwater Modelling Guidelines);
- The robustness of the Conceptual Site Model (CSM) used to define the key model inputs and model parameterisation;
- The discretisation of the model domain, including boundary conditions;
- The selection of modelling scenarios and assumptions;
- Model calibration;
- Interpretation of modelling outputs; and
- Sensitivity analysis.

As discussed in **Section 4.5**, the ITPR team relied on the expert support of Dr Stuart Brown in reviewing the groundwater modelling components of the assessment.

The finite element modelling code SEEP/W is a widely used for geotechnical applications and is considered an appropriate platform to achieve the stated modelling objectives. The model environment is a 2D cross-section orientated through the CLA with transient western and eastern boundary conditions of the rising pit lake and recovering regional groundwater levels, respectively. While the rate of rise in these boundary conditions is also a prediction, and in many ways contingent on the final filling strategy, the boundary conditions are considered appropriate in the context of the model objectives. As configured it is considered to align with a Class 1 model confidence level, as defined in the Australian Groundwater Modelling Guidelines. Class 1 models are considered to have a relatively low confidence level; however, in this instance it is considered to be sufficiently rigorous given the setting, margin of safety indicated by the modelling results and relatively modest modelling objectives.

The CSM is considered to be appropriately developed and understood to reasonably inform the development of the model environment. The physical characterisation of the leached ash, encapsulating material and surrounding fill, including additional testing requested by the ITPR team (**Section 5.4.1**) has resulted in a robust and volume-based understanding of the key physical and chemical parameters considered relevant to the submergence of the CLA. Residual uncertainty has been addressed through the model sensitivity analysis process.

Given that the focal point of the modelling is currently unsaturated, the model is unable to be effectively calibrated to a historical dataset or present day conditions. This is consistent with a Class 1 model designation under the Australian Groundwater Modelling Guidelines (Barnett et.al., 2012).

The ITPR team provided considerable feedback on the underlying modelling assumptions, the interpretation of modelling outputs and sensitivity analysis. The primary areas of concern for the ITPR team were the assumptions that the CLA was a dry deposit with no advective potential until the point of inundation and saturation by rising water levels. In reality, the ash deposit is likely to be unsaturated, but large portions of it were placed as a wet slurry, raising the prospect of historic

excursions of solutes from the CLA into the surrounding fill. This was explored through sensitivity analysis applied to particle tracking, whereby hydraulic conductivities within the CLA were increased by three orders of magnitude to more closely approximate the lower hydraulic conductivity of the surrounding fill material, effectively modelling the behaviour of a conservative solute migrating within the higher permeability fill.

Throughout the scenarios utilising the adopted model parameters and subsequent sensitivity analysis, particle movements from within the CLA were shown to be small and substantially less than the distance to receptors, including the developing water body, over a 100 year simulation timeframe. Particle movements assume a conservative solute unaffected by attenuation factors such as adsorption, degradation or diffusion. The movement of many contaminant species would be expected to be slower due to these factors.

Overall the modelling is considered to support the field evidence that the CLA and clay-rich encapsulating material are likely to provide an effective advective impediment to solute migration from the CLA into the surrounding environment over any reasonably foreseeable management timeframe.

5.4.3 Future Monitoring

It is understood the future monitoring requirements will be formally documented in separate monitoring plans and are not described in detail in the CLARA. Rather the CLARA provides the overall monitoring principles and these have been subject to review by the ITPR team. The monitoring requirements relevant to the CLA fall into the following categories:

- Monitoring of pit lake water quality;
- Monitoring of surrounding groundwater quality; and
- Monitoring of CLA cap integrity.

Pit lake water quality, in relation to any impacts from the CLA during and post submergence, is proposed to be monitored in comparison to the Interim WQPTs. The ITPR teams views on this item are discussed in **Section 5.2**. In addition to the targets themselves, the ITPR team also noted a lack of clarity as to how these targets would be applied (i.e. sampling locations, frequencies and target analytes). However, it is understood that these matters will be articulated in a separate monitoring plan.

Surrounding groundwater quality is proposed to be monitored using the existing monitoring well network at the margin of the current mine pit. The ITPR team raised concerns regarding the appropriateness of these locations to monitor the impacts from the CLA. However, in the context that the purpose of the monitoring (and the ITPR team's scope of review) was specific to the activity of submerging the CLA, it is acknowledged that there are practicability constraints in relation to monitoring bores within a waterbody. Furthermore, the CLA lies within a much larger and highly disturbed former mining environment where it may be difficult to discriminate between impacts from the CLA and impacts from other mining induced disturbance. In that context, monitoring locations at the periphery of the mine void do present reasonable sentinel monitoring points to detect excursions to the wider environment.

Similar to the monitoring the pit lake water quality, the CLARA does not articulate the details of the groundwater monitoring program, including frequencies, analytes and contingency actions. These would need to be documented in an appropriate water quality monitoring plan.

Regarding cap integrity during and post lake establishment, it was agreed that an appropriate monitoring regime would be implemented to address the following areas of concern:

- Degradation of the cap through wind-driven wave action and other erosion processes, particularly when the water level coverage of the CLA was shallow; and
- Degradation of the cap through biological processes, including bioturbation (e.g. burrowing organisms).

Similar to other elements of the monitoring program, the CLARA does not articulate these requirements in detail; however, the following commitments have been agreed as part of the ITPR process:

- A monitoring and maintenance program, including cap inspection and repair (if required) will be implemented for the period up until the CLA is fully submerged;
- A program of bathymetric survey, or other similar suitable technology, will be implemented post CLA submergence to confirm the ongoing integrity of the cap (i.e. through monitoring of cap surface elevation), until such time that it is established that the cap is stable.

A detailed monitoring program will need to be established to formalise these commitments including frequencies, trigger levels, contingency actions, reporting requirements and rationalisation/cessation criteria.

5.5 Detailed and Verifiable Confirmation that the Proposal Constitutes Best Available Techniques

EHS Support undertook a literature review of Australian and international examples of long-term coal combustion ash (CCA) management practices, which included some examples of subaqueous deposition of CCA materials.

Most CCA materials globally are dry managed in the sub-surface (i.e. ash landfills) or wet managed in impoundments (i.e. ash ponds), with both methods producing a range of well documented environmental hazards. Increasingly, in jurisdictions including Europe and China, CCA is recycled for use in construction and infrastructure projects. The subaqueous deposition examples were reported from Germany, where ash was deposited in lakes as an amendment to reduce acidity and were presumably uncapped.

On the basis of the review completed by EHS Support, there appear to be few examples of the submergence of a capped CCA deposit; however, the proposal has much in common with the management of dredge spoil which is conducted in subaqueous environments worldwide. In dredge disposal grounds, dredged sediments, often containing heavy metals and other contaminants derived from industrial port environments are deposited in subaqueous impoundments and capped with clean material with the following objectives:

- Physical isolation of the impounded material;
- Stabilisation and prevention of erosion and resuspension in the water body; and
- Reduction of dissolved contaminant flux to the overlying water body.

These objectives are considered to apply equally to the CCA at Anglesea, where it is considered, based on the assessment work to date, that the encapsulating materials are likely to achieve these objectives.

On the balance of the assessment work undertaken, and the assumptions inherent in the proposal, the ITPR team is of the view that the proposed management of the CCA at Anglesea in some cases exceeds the accepted standard for CCA management in ash ponds, which are often unlined, and is comparable to best available techniques as it applies to similar materials in subaqueous environments. It could be argued that dry management or recycling would also represent best available techniques; however, neither are considered reasonably practicable under the logistical circumstances and pre-existing regulatory approvals process.

5.6 Measures taken to Comply with the General Environmental Duty, relevant Environmental Reference Standards and principles of the Environment Protection Act 2017

Measures taken to comply with the GED, and other applicable legislation, is outlined in Section 3 of the CLARA.

The works completed in relation the CLA, including the design and capping and subsequent characterisation and risk assessment process, is considered to be consistent with the GED which is to minimise risks to human health and the environment so far as reasonably practicable. It has been demonstrated to a reasonable level of certainty that the cap and encapsulating materials surrounding the CLA have properties consistent with best practice objectives for landfills in Victoria as relevant. The adoption of best practice ensures that risks are minimised to the extent reasonably practicable and is consistent with the requirements of GED. Further, this approach is comparable to best available technologies and techniques given the environmental and regulatory context.

The ERS is most relevant to the consideration of the surface water and groundwater environmental values adopted. The ITPR team provided some feedback on this element of the work in terms of the application of environmental values to artificial water bodies and ensuring the environmental value of water-based recreation (aesthetic enjoyment) was appropriately considered in the context of the ways in which the community would be able to make use of the future waterbody. The environmental values that are proposed to be protected in the mine water body of water dependent ecosystems and species (consistent with that in the surrounding environment) and water-based recreation (aesthetic enjoyment) are consistent with the use for which the mine water body is intended; it is understood that the relevant regulatory authorities have determined that neither primary nor secondary recreational uses are intended end uses of the water body.

The proposed measures are also in alignment with the principles of environment protection as outlined in the *Environment Protection Act 2017*. Notably the CLA management is consistent with the principle of proportionality, that is, the design, construction, monitoring and maintenance of the CLA have been developed in a way that is proportionate to the risks identified. Characterisation of the ash indicates that the principal environmental risks associated with the CLA are associated with potential leaching of trace metals to the future mine water body and groundwater, albeit at very low rates due to the low permeability of the ash and encapsulating materials. The ITPR team is satisfied that these risks are appropriately mitigated by the encapsulation approach adopted, which would be verified through future monitoring and maintenance (as necessary) programs.

In addition, with regard to the waste hierarchy as outlined in the *Environment Protection Act 2017*, the waste could not be avoided and opportunities for reuse and recycling were not considered reasonable and practicable under the logistical circumstances and pre-existing regulatory approvals process. Recovery of energy is also not applicable. Therefore, the next preferred approach in the waste hierarchy, being containment, has been adopted.

The ITPR team is also of the view that evidence-based decision-making has been applied, and this was emphasised through the process by ensuring that retrospective testing was conducted to address any data gaps. Finally, the approach adopted has considered the uncertainties involved in the characterisation and applied sufficient conservatism in approach. For example, the groundwater modelling includes a sensitivity analysis to evaluate risks under less conservative circumstances. This is consistent with the precautionary principle.

6 Conclusions

Based on the review undertaken the following conclusions are drawn with respect to the review objectives:

- The combined assessment and characterisation work on the physical properties of the CLA is considered to have been completed in accordance with appropriate and relevant legislation, guidance, and industry standards to the extent practicable. The outcomes of this work are considered to be a reasonable basis from which to assess the likely future impacts on the surrounding environment from the submergence of the CLA within the pit lake.
- Numerical modelling has been utilised to make predictions regarding the future environmental performance of the CLA cap and other encapsulating materials. The model it is considered to be sufficiently rigorous given the setting, margin of safety indicated by the modelling results and relatively modest modelling objectives.
- The numerical modelling, together with other lines of evidence including the site-specific physical characterisation of the materials, has been used to inform the risk assessment process. The risk assessment concludes that the activity of submerging the CLA beneath the pit lake represents a low risk of adverse environmental outcomes in both the short and long term.
- In the context of the specific assumptions (**Section 4.1**), the history of regulation and the environmental setting, the ITPR team is of the view that the submergence of the CLA does present a low risk of adverse environmental outcomes for surface water and groundwater and that the approach is consistent with previous regulatory directions and broader principles of environmental protection, including the GED.
- Future monitoring and verification of the environmental performance is considered to be a key tenet of sound environmental management. The CLARA provides the overall monitoring principles which the ITPR team considers appropriate. It is understood that specific detail on the

future monitoring requirements, trigger levels and contingency actions are to be prepared prior to the submergence of the CLA. The ITPR team emphasises that an appropriately detailed water management plan as proposed should be developed and implemented so as to provide a robust framework for future environmental management of the CLA.

7 Closure

Please contact either of the undersigned should you wish to discuss any matter regarding the ITPR.

Yours sincerely,

This report was prepared for the sole use of Alcoa of Australia Limited and should not be relied upon by any other person. None of BlueSphere Environmental Pty Ltd or any of its related entities, employees or directors (each a BlueSphere Person) owes a duty of care (whether in contract, tort, statute or otherwise) to any third party with respect to or in connection with this report and no BlueSphere Person accepts any liability for any loss or damage suffered or costs incurred arising out of or in connection with the use this report by any third party.

The report has been prepared with the objectives and scope of work outlined in the proposal dated 18 February 2022 and subsequent variations. The work was carried out in accordance with the Contract CW2303449 .

The conclusions and recommendations provided in this report are based on available information and it is possible that different conclusions and recommendations could be made should new information become available, or with changing site conditions over time. These opinions, conclusions and recommendations are subject to uncertainty given the potentially complex nature of any subsurface environment. Variation in soil and groundwater conditions may vary significantly between the specific sampling and testing locations and other locations at the site.

The report will not be updated if anything occurs after the date of this report and BlueSphere Environmental Pty Ltd will not be obliged to inform any person of any matter arising or coming to its attention after that date.

Ash Risk Assessment, Hydrogeological Modelling, Former Coal Mine, Anglesea, Victoria

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (6 April 2022)	EHS Support response to Reviewers Comment (6th June 2022)
Conceptual Site Model and Parameterisation					
1	-	General	0	It would be useful to explain how this modelling does (or does not) fit within the Australian Groundwater Modelling Guidelines. This is likely to be of interest to the regulators.	The SEEP/W model is a conservative assessment of the risk of a conservative constituent (particle) migrating from the ash under advective flow. If unacceptable risk were identified as outcomes of the modelling then the model would have been updated to inform the level of risk and this would also be coupled with the modelling described below. However, at this stage and conservatively the risks appear to be low and the coupling with a more detailed numerical model is not warranted. A detailed numerical model is currently in development in accordance with the AGWG. This is a catchment wide (Jan Juc GMA) groundwater model which is being peer reviewed by Hugh Middlemis. The objective of this model is to ascertain if a sustainable pumping rate can be used for mine rehabilitation strategies as well as inform DELWP on Barwon Waters Bulk Entitlement.
2	-	General	0	The model is conceptualised on the basis that the ash is only source of contamination to the surrounding environment. What is the background groundwater quality in the vicinity of the ash deposit and are there other sources of similar contaminants? The nature and condition of the surrounding environment is relevant, in that environmental risks may be perceived to be more tolerable in a disturbed environment compared to a pristine environment. Background is also a relevant consideration in the regulatory framework in Victoria, for example, where background water quality is elevated with respect to a specific parameter, the background becomes the objective.	It is recognised that the ash has been conceptualised as the only source of contaminants in the CSM. Currently there is no groundwater within the vicinty of the ash deposit(with the exception of intermittent water in DBG MB6). The aim of this modelling task was to conduct a high level assessment of the hydraulics of particle flow within the model domain. By using particle tracking (without attenuation or retardation) conservative assessment of constituent migration could be assessed. Dependent on the outcomes of this task, fate and transport modelling of specific constituents and background concentrations could be explored. As the outcome of this task was that particle tracking did not suggest migration of particles from the ash, through the clay-rich layer and into the fill material, it was concluded that a fate and transport modelling assessment was not necessary. This will be re-evaluated depending on the outcome of the revised sensitivity analysis of the fill material permeability.
3	2	Background	0	Reference is made to ash being allowed to "naturally dewater". Can you clarify what the likely fate of the water would have been (i.e. did the supernatant discharge to the pit lake/sump, evaporate or seep into underlying fill).	The dewatering of the ash was a combination of evaporation, lateral seepage into fill material (minimal vertical downward seepage) and direct discharge to the water body. In the shallow fill material, lateral seepage is assumed to be be dominant over vertical (downwards) seepage due to anisotropy of the fill material and evaporative flux. Supplementry analysis (total and leachable fraction) has been conducted in the decant are and discussed within the report.
4	2	Background	0	Reference to "encapulation" implies that the "clay-rich layer" exists above, but also underneath and to the sides of the ash deposit. Is this the case, or is it better conceptualised as a cap only?	The ash is covered by a consolidated clay rich layer. Only the covering layer has been laid down in lifts of approximately 300mm and compacted with the back of a bucket. The minimum 1m thickness of covering clay was tracked with a doser. The north-east boundary of the ash deposit is formed by the historical haul road into the mine pit. This road has been progressively formed using the same clay-rich material (sandy clay) as the covering layer. Beneath the consolidated ash and to the remaining sides fill material exists which range from minor sand lenses to clays. Supplementary permeability tests have been conducted at multiple locations areound the CLA area which verifies low permeability (average <1x10-9 m/s) material surrounding the CLA area
5	2	Background	1	It is understood that an Ash Risk Assessment will be prepared. The modelling report will need to be updated to include a summary of the findings of the Ash Risk Assessment report. This will assist in providing context regarding the significance of the consolidated ash deposit in terms of environmental risks and commensurate management necessary to minimise risks to the environment.	Noted and report can be updated as recommended. Report has been prepared and updated
6	3	Aim and Objectives	0	As above, the precise extent of the clay-rich layer is, to this point in the report, unclear and requires clarification.	Refer to Figure 1 and figure 4 which show the inferred extent of the consolidated ash deposit. This extent will correlate with the extent of the compacted clay-rich layer cover. Supplementary field works have confirmed extent of CLA area
7	4.1	Dispersivity/Reactivity	0	Materials testing undertaken to date (dispersivity and permeability testing) has been undertaken using deionised water. It is recommended that testing also be undertaken using saline water to simulate interaction with water in the pit and groundwater, noting that cation exchange reactions can alter the performance of clay materials.	We note that higher salinity pore water has the potential to alter the performance of the clay (specifically permeability). The ash, fill material and clay-rich material are extremely saline (ECe >16 dS/m) and highly sodic. If dispersion is likely it will occur due to the salinity of the existing clay-rich layer porewater and not just by the action of the ash (or fill material) porewater on the clay-rich material. If there is no dispersivity contrast between ash and clay-rich layer/fill material porewater, is additional material testing for salinity dispersivity warranted? Supplementary permeability tests (both saline and de-ionised water) have been conducted and the results incorporated into the updated report
8	4.2.1/4.2.2	Lithological Characteristics	0	These sections suggest that, in the vicinity of the coal mine the DBF (silts to fine sand) was 20 m thick and the BF was 32 m thick (comprising 20 m of fine-coarse sand and 12m of silt). This would tend to suggest the fill material, the it is understood constitutes re-worked DBF and BF would be relatively sandy. A description of the observed or expected fill profile in the vicinity of the consolidated ash should be described based on the current state of knowledge. This will assist in providing further substantiation regarding the hydraulic properties of the fill material subsequently adopted in the modelling. This should include reference to the pre-existing haul road on the northern margin of the deposit, batter slopes to the east and south, and the constructed berm on the western end of the deposit.	In addition to the in-situ geological descriptions, reference will be made to borelogs where overburden material has been encountered in the vicinity of the mine pit. The borelogs describe the overburden/fill material as mainly clayey sands, sandy clays with occasional sand horizons. Supplementary field works have confirmed the textural characteristics of the fill material as mainly sandy clay
9	5.2	Demon Bluff Group	0	Some comment should be provided in relation to how the K data from Beattie (2003) compare to other published data or text book values. This will assist validating these parameters.	Additional discussion will be added to address this response. Domenico and Schwartz (1990) have published values (m/sec) for clay ($5x10^{-9}$ to $1x10^{-11}$), silt ($2x10^{-5}$ to $1x10^{-9}$) and sand ($6x10^{-4}$ to $9x10^{-7}$). Beattie (2003) values fall within the range of the Domenico and Schwartz (1990) values. Hydraulic conductivities listed in Hazleton and Murphy (2016)* have published values (m/sec) for clay ($1x10^{-9}$), silt ($3x10^{-6}$ to $1x10^{-9}$) and sand ($2x10^{-4}$ to $3x10^{-8}$). Beattie (2003) values fall within the range of the Domenico and Schwartz (1990) and Hazleton and Murphy (2016) values. *Hazleton and Murphy (2016) Interpreting soil test results 3ed Slug test results for selected DBF bores in the power station area can be provided. As part of the recommendations a slug test is being performed on the only saturated bore in the overburden (DBG MB6) and the results will be compared to other slug test data from the shallower bores in competent (natural) DBG material. Additional field sampling and characterisation maybe conducted. The above has been incorporated into the updated report
10	6	CSM	0	Definition of "fast fill" at Paragraph 3 does not seem to describe filling via groundwater extraction, as currently proposed.	The used of extracted groundwater is the preferred option for a fast fill scenario, however, there are other potential sources of water that could be used to achieve a 'fast fill'. Description will be edited to make more explicit that this fast fill scenario uses abstracted UEVF groundwater as the source of water.
11	6	Figure 6-1	0	As above, diagrammatically represented as being completely encupsulated. To what extent does this represent the reality? The nature of the fill material surrounding the consolidated ash should be described.	The conceptual model description will be modified to describe the placed clay-rich layer cover and the clay-rich characteristics of the fill material surround the consolidated ash on the sides and base.
12	8	Model Construction and Input Parameters	0	Construction of the model domain such that the ash and clay rich material constitute one region raises the issue of the fate of water within the ash immediately following placement. The model, as constructed, effectively places water draining from the emplaced ash into contact with the underlying fill material. Clarifying the lithology beneath the consolidated ash (i.e. that a continuous low permeability clay layer is present beneath the ash) is therefore of critical importance.	The conceptual model description will be modified to describe the placed clay-rich layer cover and the clay-rich characteristics of the fill material surround the consolidated ash on the sides and base.
13	8	Model Construction and Input Parameters	0	Hydraulic conductivity inputs (at least for the clay rich material) are based on laboratory permeability tests, rather than pumping tests. Can you comment on the likely impacts of sample disturbance, but also potential macro porosity features such as fissures and cracks in the cap material. Has this been addressed via sensitivity testing?	The clay-rich material and fill material are both distrurbed materials derived from the process of removing overburden during open-cut coal mining. The material has been disturbed prior to taking samples but the process of collecting the samles is unlikely to affect the permeability results bythe introduction of fissures or cracks. Macro porosity changes has been explored through the sensitivity analysis where the permeability of the ash was increased by 3 orders of magnitude (noting that the consolidated ash model region incorporates the clay-rich layer).
14	8	Model Construction and Input Parameters	0	Can you clarify further how the western boundary condition functions as water levels rise? Does the model domain include bathymetric information that allows a water body with a level surface to develop, or is it simplified such the the water level in the model domain is linear from the western boundary condition to the eastern boundary condition?	The water surface that develops in the water body is linear and the equipotential surface (or water table) between the western and eastern boundary conditions is dependant on the material properties and corresponding pore water pressures. During a transient simulation the water level between the western and eastern boundary conditions is not always linear but depending on the length of the transient simulation and the material properties and hydraulic functions, linearity will be achieved at the end of the simulation.
15	8	Model Construction and Input Parameters	0	Recovery in groundwater levels in the DBG is modelled as a linear function, when in reality this might be expected to be more asymptotic. What effect would this simplification have on model predictions, if any? Would it be correct to say that an asymptotic rise could increase the period of time over which hydraulic gradients could slope away from the mine void?	It is recognised that the hydraulic functions are linear and that they are more simplified than what would be expected to occur in an anisotropic model domain. However, the linear hydraulic functions are applied to the boundary of the regions comprising fill material and consolidated ash. The differing material properties of these regions does induce an asymptotic increase in the water table within these regions. It is accepted that non-linearity in the boundary conditions could both decrease or increase the period of time over which hydraulic gradients induce groundwater flow radially away from the water body. However, a linear function provides a reasonable estimate of the rate of groundwater water level recovery in both the fill material and consolidated ash regions.
16	8	Table 8-3	0	Check stated groundwater flow directions - appear incorrect (e.g Scenario 1a West (-39.79) to East (-39)	Scenario 1a has been modelled as an east to west groundwater flow, i.e., eastern boundary condition head -39 mAHD and western boundary condition head -39.79 mAHD. Table 8-3 has been corrected to reflect this.
17	8	Model Construction and Input Parameters	0	Rainfall and evaporation are not considered significant enough components of the water balance to warrant modelling or capture in the recovery functions. Some further rationale would be useful to justify this assumption.	Conceptually (Section 6), rainwater has been considered as part of the water budget within the model domain. However, evaporation and the low permeability of the fill material results in rainfall being a very small contributor to both the development of the water body and infiltration through the unsaturated zone to groundwater. The model setup uses boundary conditions to simulate the development of a water table within the model regions based on a total water head and not a water flux so the omission of the minimal contribution of rainfall (minus evaporation) does not affect the overall outcome. Additionally, the greenamp equation has demonstrated (detailed numerical model) rainwater infiltration is negated by evaporation by capillary rise in the vadose zone. Additional text added to report to justify the assumption
18	8	Model Construction and Input Parameters	0	It should be stated that a key assumption is that the consolidated ash remains a geotechnically stable landform. Whilst not specifically relevant to the modelling, it is anticipated that geotechnical considerations will need to be addressed as part of the ash risk assessment response to EPA. Although beyond our area of expertise, geotechnical advice in relation to bouyancy of the ash deposit, differential settlement induced by the overlying water column and erosion via wave action during filling of the pit may be relevant.	MiningOne have completed these assessments and will be included in the overarching Ash Risk Assessment report. This information will be included as part of the updated MRCP, not the Consolidated Leached Ash Risk Assessment as indicated above
19	9.1	Scenario 1	0	Scenario 1 does not acknowledge the presence of water in the ash itself, which was deposited wet. As per previous comment, the fate of this water should be clarified. Perhaps a further scenario could be incorporated to define the initial conditions, where by a head from the ash layer is applied to the underlying fill material to simulate the initial migration of solutes from the ash into the underlying material. This may then inform refinement of the placement of particles for particle tracking.	The presence of water within the consolidated ash (the residual water content) was considered during the SEEP/W model development. Previous versions of the model allow you to use the sample function estimation method and specify a saturated amd residual water content within material properties. However, the current version only allows input of a saturated water content and a function is applied dependent on the sample material (soil type) selected. Alternatively the user can create a function based on a upper and lower volumetric water content (VWC) value however this is not recommended by Geostudio without using either a closed form solution or a predictive method. To explore the potential infuence a higher residual VWC has on unsaturated flow, a user derived function was used with a VWC range of 0.25 to 0.43. The results for elements within the consolidated ash region and in elements directly surrounding this region in the fill material region were queried for VWC. In Scenario 1b transient conditions 2016 to 2022, the VWC within the cosolidated ash region is at or near saturation while the fill material is close to residual values (0.02). It appears that the consolidated ash is at field capacity and there is no free draining water from the consolidated ash region into the fill material.
20	9.2	Figure 9-8	0	Caption states easterly groundwater flow, but this appears to be contrary to the boundary conditions and the flow vectors	Correct, the groundwater flow is from the east to the west i.e., westerly groundwater flow. Report corrected to reflect this.

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (6 April 2022)	EHS Support response to Reviewers Comment (6th June 2022)
Conceptual Site Model and Parameterisation					
21	9.2.1	Particle Tracking	0	The placement of particles within the ash itself, and only once the ash becomes saturated by groundwater and water body recovery, does not acknowledge that the ash was placed wet and solutes likely exited the ash much earlier than modelled. This requires some consideration as previously suggested. A possible workaround to the lack of convergence when placing particles in unsaturated parts of the model domain, would be to place particles immediately outside the ash to simulate remobilisation of historic discharges from the base of the cell. Further groundwater monitoring of the underlying aquifer may shed light on any historic impacts of this nature.	Particle tracking just outside the consolidated ash region and within the fill material model region will be conducted to explore the potential for seepage from the ash into the surrounding fill material.
22	9.2.1	Particle Tracking	0	The validity of the particle tracking approach could also be tested by modelling seepage through the clay rich layer based on a likely head (albeit declining) that would have developed in the ash post placement. This also calls for clarity on whether the "cap" is present beneath the cell or only above, as previously raised, and what verification there is regarding the properties of this material.	Is the reviewer suggesting simulating a declining head on a clay layer in isolation to the modelling performed? The CSM shows that the water head on the clay-rich cover will be increasing over time (not declining) until a 'steady-state' water body elevation is achieved. Additional explanation will be provided within the report describing the presence of low permeability fill material beneath the consolidated ash and clay-rich material cover on top of the consolidated ash. Additional field sampling to address data gaps has been proposed in the draft SAQP.
23	9.2.1	Particle Tracking	0	This section discusses the failure of the model to converge where particles were placed within unsaturated part of the model. Where convergence is an issue, it is suggested that calculations using first principles (i.e. Darcy velocity assuming saturated conditions) could be used to validate scenarios where this is the case.	Darcy flux calculations indicate 6cm/yr travel distance for a particle within the consolidated per year using a hydraulic gradient of 1. Shallower gradients will induce a lower flux Conceptually, the hydraulic gradient will change considerably as groundwater inundates the consolidated ash until steady state water body elevations are achieved. Gradients that develop are dependant on material properties and the fill scenario (slow or fast).
24	9.2.1	Figure 9-10	0	As above, text refers to an easterly flow direction. The flow vectors can be hard to resolve, but both the flow vectors and boundary conditions on the figure seem to be describing a westerly flow - please clarify.	Correct, the groundwater flow is from the east to the west i.e., westerly groundwater flow. Report corrected to reflect this.
25	9.2.1	Table 9-3	0	As above, placement of particles could be more conservative. Placed just outside the cell to simulate seepage from when the ash was saturated, they would travel considerably further.	As stated above particle tracking just outside the consolidated ash region and within the fill material will be conducted to explore the potential for seepage from the ash into the surrounding fill material.
26	9.4	Sensitivity	0	The model is clearly sensitive to the hydraulic conductivity of the ash and/or surrounding encapsulating clay, which stands to reason. The existance and properties of the clay-rich material underlying the cell would seem to be critical to the assumptions inherent in the model. What physical testing of this material (specifically from beneath the cell) has been undertaken?	Based on the known elevations of the consolidated ash placement, six samples were collected below the consolidated ash and within the underlying fill material. Two of these samples were identified as consolidated ash in the report which was in error and will be corrected in the new draft report. In summary, 7 samples were collected within the clay-rich cover layer, 3 samples on the clay-rich/consolidated ash interface, 10 samples within the consoidated ash, 1 sample within the interface of the consolidated ash/underlying fill material and 6 samples from the underlying fill material. Of these samples 7 ash, 4 clay-rich layer and 1 fill material were tested for permeability and dispersivity. As part of the recommendations a slug test is being performed on the only saturated bore in the overburden (DBG MB6) and the results will be compared to other slug test data from the shallower bores in competent (natural) DBG material. Additional field sampling and characterisation maybe conducted. **Above comment modified 31/05/2022 Supplementary field works have collected additional data to support the ealry assumptions related tot he CSM.
27	10	Summary and concs	0	A key assumption of the modelling is that ash-derived solutes did not exit the cell during the period that the cell was saturated from wet placement. The validity of this assumption should be explored and model scenario (or at least a sensitity test) should be derived to assess the possible outcomes under a scenario where solutes did exit the cell during this period.	As stated above particle tracking just outside the consolidated ash region and within the fill material will be conducted to explore the potential for seepage from the ash into the surrounding fill material. If the outcome of the particle tracking suggests migration within the fill material additional fate and transport assessment could be warranted. Placement of particles just outside the CLA area did not warrant additional F&T modelling
28	10	Summary and concs	0	Particles are shown to move distances that are a small fraction of the model cell size in many cases. Can you clarify how the model calculates these travel distances. Also it would be worth validating these travel distances using first principles - are the particle tracks reasonable based on the prevailing hydraulic parameters?	The particle velocity and movement are calculated by the water/air flux and material porosoty or saturated volumetric water content. Particle movement is the same as advective transport without dispersion. A document 'Seepage Modelling with SEEP/W" has been attached with these comments. Section 13 provides further detail on the water flow PDE's principles and how these are applied to the finite element flow calculations.
29	11	Recommendations	0	If further samples of the clay rich material are to be collected, it would useful to collect samples of the clay underlying the cell for permeability testing, including using a saline eluent. Consideration should also be given to undertaking materials characterisation on the side-walls of the cell. Exploratory drilling can be used with selective permeability testing to provide sufficient spatial coverage, supplementing the existing data. There are opportuntities to convert some exploratory boreholes to monitoring wells (sacrificial) focussed on monitoring the consolidated ash until it becomes submerged. It is expected that EPA would expect groundwater monitoring wells be installed as part of considering the approval.	As noted above 6 samples of the underlying fill material were collected in September 2021. Of these samples 3 under went permeability analysis, reporting hydraulic conductivities of $6x10^{-8}$ to $4x10^{-9}$ m/sec. The need for addiitonal field intrusive investigations, sampling/analysis (refer comment 26) and installation of monitoring wells will be assessed. Supplementary fieldwork was conducted to obtain addiitonal data to support the numerical modelling. Additional bores/wells are not considered necessary at the present moment.
30	11	Recommendations	0	The additional fill material samples (particularly those from beneath the cell) may be able to be used to further assess the possible excursion of ash-derived solutes from the cell historically. This may be able to be assesed through total analysis of the soil, leach testing, cation exchange testing. It would be prudent to consult with a landfill design engineer to ensure that appropriate tests and frequencies are obtained to satisfy expected EPA requirements, noting there are some very specific and nuanced testing requirements in the BPEM (whilst not directly relevant to consolidation of ash, specific elements of the BPEM are expected to provide useful benchmarks for best practice waste containment).	The testing to date has been informed by Steve Cambridge (environmental auditor) and David Ife (landfill engineer specialist). It is noted that additional testing has been considered.
31	Appendix C	Borelogs	0	The borelogs reviewed do not appear to show a specific ash layer, rather silts and clays with what appears to be a minor proportion of ash. Can you please provide further clarification regarding the nature of the ash, is it mixed with overburden material or are there discrete layers that perhaps could be highlighted more clearly on the logs using the graphic log.	Further detail will be provided as to the ash placement activities into the pit and consolidation into the current area. Historically, ash was trucked to the edge of the void and tipped over the edge as solids and solids with ash pond water. This activity entrained overburden material into the ash and it is evident in the photographic logs that the ash does not visually represent traditional ash characteristics (particularly in colour). Aerial photographs will also be provided to visualise the tipping area (as new Figure 2).
32	9.4	Sensitivity Analysis	0	The sensitivity analysis considers variations in the water body fill rate and the hydraulic conductivity of the coal ash fill material. The latter scenario assumes a hydraulic conductivity 3 orders of magnitude higher than the geometric mean of the samples tested (2.9 x 10-6 m/sec versus 2.9 x 10-9 m/sec). This is well outside the range of samples and overly conservative. Also, presumably if long term groundwater flow is towards the water body (and slightly upward), then the solute will be travelling through the backfill material, so it would be more relevant to assess uncertainty in the backfill characteristics.	The comment is noted and additional sensitivity analysis of the back fill material will be conducted which will assess the lower hydraulic conductivities of the fill material. The initial approach is valid as it does assess the higher hydraulic conductivities which are likely associated with the medium and coarse grained sand stringers within the fill material. A sample was atempted to be collected in September 2021, however, due to the unconsolidated nature of the material the sample could not be recovered.
33	9.2.1	Particle Tracking	0	The discussion regarding flow paths and particle tracking on Page 31 is confusing. It states that the flow paths shown in green are not physically or realistically correct if they terminate at the base of the model (which is all but one flow path). They appear to show vertical upward flow through the cell (as do all the small flow vector arrows below the cell). Elsewhere it is stated that groundwater flow is from east to west in late time steps, so does this mean that the groundwater pressures never reach equilibrium during the simulation?	The text will be reworded to make more clear. The discussion will state the differences in particle flow during steady-state and transient simulations. It is also more accurate to state that the hydraulic gradient is mainly east to west and there is an overall net flow of groundwater from the east to the west, however, flow paths witin the model regions are a combination of horizontal and vertical. For flow path terminations at the model boundary this is simulated as a no flow boundary due to the base of the CSM represented by the basal clay. Steady state simulations have been used to show the groundwater pressures at equilibrium whihc some of the transient scenarios to not attain during the simulation period.
34	9.2.1	Particle Tracking	0	The following section (9.2.1) says that “a particle has infinite vectors to flow over time and it is not known what the particle path will be”. While I understand what the modeller is saying here, it might appear to some readers that you can’t predict the flow path, which sort of defeats the purpose of the modelling. I would suggest these sections be re-worded to clarify. Also consider annotating the cross setions to show the flow directions based on particle tracking at the associated time steps. The tables show the groundwater velocity but not clearly the direction.	This text will be reworded to provide additional clarity. Some screen shots of the particle tracking paths will also be provided in the new draft report.

Memo, SAQP Data Gap Analysis - Consolidated Ash Risk Assessment

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (17 June 2022)	Assessor's Response (23 June 2022)
1	-	-	0	Preamble: In reviewing the number of proposed samples we have considered the material volumes surrounding the consolidated ash deposit, variability in existing results and typical standards applied to comparable scenarios. For example, the landfill BPEM, whilst not directly comparable to an ash repository, does provide best practice guidance for engineered liners and caps. Section 6.4.1 specifies the following: "properties of the clay (grain size distribution, plasticity index and moisture content) tested once every 5000 m^{3}". The following comments are provided with respect to this guidance, noting that there are other elements of the BPEM related to capping such as level 1 supervision, testing during placement etc that are obviously not relevant. Rather these deviations are considered by the sensitivity analysis of the modelling.	No response necessary
2	-	Objectives and Scope	0	It is understood from your email of 15 June 2022 that permeability testing using a 5000 ppm is proposed. By comparison, the work plan outlies that the porewater salinity is ~2000 ppm. It is agreed that the higher salinity should be adopted as a conservative approach to reflect potential higher salinity that could occur within the filled water body over time due to evaporation.	Understood no further response provided
3	-	Work Plan, as amended by email of 16 June 2022	0	Further to the above, ash pore water is quoted as 2,860 uS/cm (1:5). Is this the EC of the 1:5 extract or has this been converted to pore water salinity?	The laboratory method result is the EC (1:5) and the value represents the maximum concentration reported.This value has then been used to derive a total dissolved solids concentration using a factor of 0.7.
4	-	Work Plan, as amended by email of 16 June 2022	0	In your email of 16 June 2022 you propose to decrease the number of DI permeability tests in favour of saline tests. This is considered to be reasonable as the saline tests are more likely to approximate the real world conditions. It is considered that DI tests could be ommited particularly for the clay rich layer but a sub-set should still be taken for the balance of materials (i.e. haul road etc) for comparative purposes. See comments below.	In total 25 locations will be advanced across the project area to a maximum depth of 6m. Materials encountered will be logged at each location. Number of locations per domain area as follows: Clay rich cover - 3 locations Fill material - 3 locations (same locatios as above) Berm - 2 locations Haul Rd - 9 locations Southern - 9 locations Discharge - 2 locations In summary, permeability tests to be conducted based on comments and discussions with Bluesphere below: Clay rich cover - 3 locations, 5 saline permeameter tests Fill material (below the consolidated ash) - 3 locations, 5 saline permeameter tests Berm - 2 locations, 5 saline permeameter tests, 3 DI permeameter tests Haul Road - 3 locations, 6 saline permeameter tests, 3 DI permeameter tests Southern - 3 locations, 6 saline permeameter tests, 3 DI permeameter tests Chemistry analysis will be conducted on the following: Discharge area - 2 locations, 0 permeameter tests, 6 samples for total chemistry and 4 for leachable fraction analysis at pH values. SAQP will be updated to reflect these changes.
5	-	Work Plan - Table 3, as amended by email of 14 June 2022	0	Clay rich layer: Three DI and three saline permeability tests are proposed for the clay rich layer, in addition to the 4 existing DI tests. Based on a placed volume of ~46,000 m^{3}, this would equate to a testing frequency of 1:7666 m^{3} for tests from individual locations. It is recommended that an additional two permeability tests to that proposed (i.e. five instead of 3 at individual locations) be conducted from this material giving a total of 9 individual tests. This would accord with the BPEM recommended testing frequency of 1:5000 m^{3}.	Agreed, 5 additional saline permeameter tests (at 3 locations) instead of the 3 proposed tests. No additional DI permeameter testing.Samples will be collected within the clay rich cover and fill material up to a maximum depth of 6m. SAQP will be updated to reflect these changes.
6	-	Work Plan - Table 3, as amended by email of 14 June 2022	0	Berm: Six DI and six saline permeability tests are proposed. Based on a placed volume of 24,000 m^{3}, this would equate to a testing frequency from individual locations of 1:4000 m^{3}. It is recommended that an additional one permeability test to that proposed (i.e. 5 instead of 4 at individual locations) be conducted from this material giving a total of 5 individual tests. This would accord with the BPEM recommended testing frequency of 1:5000 m^{3}.	Agreed, 1 less saline permeameter test, 5 tests in total (at 2 locations). Two DI permeameter tests. SAQP will be updated to reflect these changes.
7	-	Work Plan - Table 3, as amended by email of 14 June 2022	0	Haul Road/Southern Fill Material: The Haul Road and Southern Fill Material are considered to be critical elements of the containment system, as they effectively act as side walls. Based on the inferred areas of placed material comprising the haul road and southern fill material, there is a considerable volume of material that would need to be tested if strict compliance with the BPEM was adhered to. Theoretically, only a 1m strip of this material is necessary to meet BPEM standards. Instead, given the length of the perimeters of this material (understood to be ~900 m in total) it is recommended that a reasonable borehole spacing be adopted along these areas (e.g. comparable to that adopted for the clay rich cap which it is understood is based on guidance in AS4482.1-2005). Linking to best practice guidance provides a defensible approach. The testing frequency should also be justified in terms of the side wall material placed.	The volume of fill material in the Haul Rd and Southern area domains has been calculated using the 900m perimeter x 5m depth (1m clay rich cover and 4m consolidated ash thickness) x 1m thickness this equals 4,500m3. Using the methoddology from AS4482.1-2005 in Appendix D and an area of 7,200 m2, the recommended grid spacing between samples is 30m. However, given the presence of the placed clay rich cover and the surrounding low permeability material (as described in the CSM) a grid spacing of 50m has been adopted between locations, a total of 18 locations across these two domains. Each location will enable visual characterisation of materials to a maximum depth of 6m. Permeability testing will be conducted on 18 samples (12 saline and 6 DI water) across the two domains. Samples will be collected to represent the domains both laterally and vertically. SAQP will be updated to reflect these changes.
8	-	Work Plan - Table 3, as amended by email of 14 June 2022	0	Please clarify the thickness of the consolidated ash deposit, and what data this is based on. On revisiting the modelling report, references are made to "an average of 4 m" (Section 6) and "8 m" (Table 8-1). This is important in establishing the sampling density of the encapsulating materials.	The reference to 8m in Table 8-1 of the modelling report is a typographic error. The consolidated ash layer is approximately 4m in thickness and Table 8-1 will be updated to reflect this.
9	-	-	0	The fill material beneath the consolidated ash deposit has reported permeability values ranging between 6 x 10^{-8} m/s and 7 x 10^{-10} m/s. The initial modelling has shown that the model is sensitive to this parameter, albeit not suprisingly when a very conservative K value of 2.9 x 10^{-6} m/s is adopted. In any case, given that the reported permeabilities vary by almost two orders of magnitude and given the relevance to the model, some further testing of the fill beneath the consolidated ash should be conducted. This would assist narrowing the reasonable values to be adopted in the sensitivity analysis. As there are 4 existing tests from this material, ideally an additional 5 tests would be taken from the top 1m of the fill. This may be achieved by extending the three proposed sample locations within the clay rich layer footprint to depth (locations ADBH09 to ADBH11).	Agreed, 5 saline permeameter tests (at the 3 locations). No additional DI permeameter testing. SAQP will be updated to reflect these changes.
10		Work Plan - Table 3, as amended by email of 14 June 2022	0	Further to item 7, how was the decant water discharge spillway constructed and decommissioned. Are there gaps or redundant infrastructure in this perimeter wall? It may be prudent to reposition the nearby borehole to this location.	The spillway was simply a water spill (decant) point that was cut using earthmoving equipment to allow the water to spill out of the consolidation area during the dredging activity. It was repaired on completion using clay placed in and track rolled in approx 300mm lifts.
11	-	-	0	Further to our discussions this week, upon review it is considered that PSD and atteberg testing (plasticity index) (as suggested in Section 6.4.1 of the BPEM are not necessary. These tests are used to inform the quality of clay prior to placement, essentially acting as a proxy for the expected final permeability. In the case of a pre-existing liner, it is the ultimate permeability that is critical.	Agreed and these tests will not be undertaken

Memo, Ash Risk Assessment - Supplementary Field Sampling Results

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (20 September 2022)	Assessor's Response (06 October 2022)
1	Permeability Testing			As discussed at our meeting of 15 September 2022, the permeability testing has largely corroborated the hydraulic properties adopted in the modelling and has provided a defensible, volume-based characterisation of the materials encapsulating the ash deposit. We agree that the findings should be incorporated into the modelling report (and model itself, if required) to further justify the adopted parameters. The chemical testing has revealed some interesting observations, which the majority of comments below provided in that regard.	No response necessary
2	Permeability Testing			First paragraph, please note the highest permeability reported for both testing methods was 1 x 10^{-8}, not 7 x 10^{-8}.	I have noticed that some of the sample numbers are incorrect in the memo tables which have been revised. This revision hasn't affected the outcomes of the assessment. The maximum permeability (7 x 10-8 m/sec) was reported at location ADBH17, sample ID ANG-22-0030 (deaired analysis) - refer to Table 1
3	Permeability Testing			The geometric mean for each material group and between different testing methodologies should be provided.	The geometric mean was provided for the material groups although wasn't explicitly stated in the memo. Geometric means for both saline and de-ionised water permeabilities have now been added to the memo.
4	Chemical Testing			The memo concludes that the profile of major and minor ion concentrations (for both total and leachable fractions) is very similar for both clay rich cover material and fill material where ash pond water was historicaly discharged. However, the concentrations are appreciably higher in some cases in the discharge area (e.g. total analysis for Cl, Al, Fe, Mn and leachable analysis (particularly pH=7) for Na, Cl, SO4, Al, Fe, Pb). Variation in total concentrations of Al, Fe and Mn are possibly due to lithological heterogeniety, but the leachable fractions for compounds such as Cl and SO4 may well be due to residual impacts from the discharge of ash pond water. It would be useful to provide some commentary on this, including any materiality to the overall risk profile (which may be low), but also what this may mean for ash pond water that may have drained into the fill material below and adjacent to the ash deposit, when the ash was being dewatered.	It is acknowledged that only one sample of clay-rich cover (ANG-21-0189) has been tested for total and leachable fraction analytes and has been compared to 6 depth dependant samples of fill material (ANG-22-53 to 58) in the consolidated ash discharge area. We would disagree that the concentrations of selected analytes are appreciably higher in the fill material in comparison to the clay rich cover. If the geomean of the selected analytes in the fill material are compared to the clay-rich cover, the differences are mostly marginal (refer to tables below). It is unusual that the de-ionised water leachable fraction concentrations appear to be more elevated than pH2.9 as cations are usually leached at higher concentrations under acidic conditions and anions more strongly leached under neutral to alkaline conditions. However, it should be noted that while pH7 was requested as the leachate pH, the de-ionised water pH is observed to be variable between pH 5 to 7, which affects the comparison of sample results. In comparison the DI water is still at least 2 pH units greater than the pH2.9 leach. Samples ANG-22-0054 and ANG-22-0056 concentrations appear to skew the dataset for leachable aluminium and iron using DI water. Both samples reported the presence of coal and ANG-22-0056 reported 50% interstitial coal in the borelog, which has most likely resulted in elevated chloride, sulfate, aluminium, iron, magnesium and sodium.
5	Chemical Testing			It would be useful to prepare a graph or similar allow for direct comparison between pH 2.9 and pH 7 leachability results. An initial review indicates that the analytes are more leachable at pH 7 than pH 2.9. This should be explained from a geochemical (e.g. mineral stability) standpoint as this will form an important line of evidence regarding potential impacts to the water body which we understand is likely to have acidic pH conditions when filled.	As mentioned above while pH7 was reqested as the leachate pH, the de-ionised water pH is observed to be variable between pH 5 to 7, which affects the comparison of sample results. However, the DI water is still at least 2 pH units greater than the pH 2.9 leach and both the clay-rich cover and discharge area sample respond similarly, i.e. analytes appear to be more soluble at a higher pH (lower acidity conditions). If these results are representative of geochemical conditions in ash porewater (more alkaline), any porewater mixing with the surrounding acidic groundwater (based on DBG MB6 geomean of pH 6.6 but gradually decreasing over time) and more acidic water body (geomean pH 3.65) would be expected to have decreased solubility and less mobility. However, I am still not convinced the results are representative or reproducible and further investigation may be required.
6	Chemical Testing			Last paragraph states that leachable ion concentrations in ash solids have diminished overtime. It is not apparent from the data presented what is the basis for this conclusion.	This observation relates to data provided and discussed within the consolidated ash risk assessment report which will be provided imminently - hopefully this week.
7	Comparison of Ash Leachable Fraction with Water Body and Groundwater Quality			We agree that a comparison of ash leachable fraction with current water body quality results in similar concentrations for many constituents, but it is currently unresolved whether current water body quality is an appropriate or reasonable benchmark. It is noted that many constituents in the ash leachable fraction are substantially elevated relative to groundwater in DBG MB6 (e.g. Al, B, Ca). We understand that the development of performance targets is the subject of a seperate scope of works being undertaken concurrently.	If the water body is to act as a terminal sink for groundwater, once the fill material becomes saturated any constituents from the consolidated ash porewater will migrate towards the water body. Therfore, we selected the water body as a receptor and the water quality has been compared to the ash porewater quality. We accept that the water body water quality may change over time but the performance targets will capture this variation. It is also expected that DBG MB6 groundwater quality will potentially vary over time as the fill material saturates.
8	Comparison of Ash Leachable Fraction with Water Body and Groundwater Quality			Can some further justification be provided as to why sample ANG-21-191 is a representative benchmark for ash, noting that higher concentrations were reported for some analytes (e.g. sodium, chloride, aluminium, iron) in samples from the discharge area at pH 7 (acknowledging those results are not ash per se). It is acknowledged this information may be presented elsewhere, however, it is not evident when this memo is read in isolation.	Sample ANG-21-191 reported the most consistently elevated leachable fraction concentrations (at pH2.9) in comparison to the other 7 samples collected in 2021. Detailed total and leachable fraction analysis will be provided with the consolidated ash risk assessment report.
9	Ash Risk Assessment Updates			We agree with the concluding remarks. Please ensure comments provided on Document 1 of this IRR are also incorporated into the revised modelling report.	Agreed, no further comment.

Project Name: Independent Technical Peer Revie
BlueSphere Job No: 31098.01
Client: Alcoa of Australia Limited
Assessor: EHS Support — Memo, Alcoa Anglesea Mine Water Body and Groundwater Water Quality Performance Standards

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (29 September 2022)	Assessor's Response (3 October 2022)	Reviewer's Response (9 December 2022)
1	NA	Water Quality Standards and GED Overview		The purpose of the water quality performance standards should be described. It is understood that they are proposed to be developed to a) verify that the environmental values that are to protected are not being compromised, b) to verify that the consolidated ash deposit is not deleteriously impacting upon surface water quality in the mine water body and c) that potential risks to human health and the environment are being minimised so far as reasonably practicable.	Comment is noted. The purpose of the standards will be further incorporated into the memo.	Noted
2	NA	Water Quality Standards and GED Overview		Further to the above, the introduction would benefit from context regarding the conceptual site model associated with the filling of the mine void, which then informs potential viable exposure pathways relevant to the mine water body. Specifically, it is understood that groundwater will migrate away from the mine void potentially to off-site groundwater receptors whilst the mine water body is in the process of filling (and the adjacent formations recover). Once the groundwater levels have recovered and the mine void becomes a permanent groundwater sink these pathways will no longer exist. Direct exposure pathways associated with the pit such as risks to ecological receptors, and risks associated with potential overtopping during extreme weather events also exist. Enunciating these pathways will assist in deriving and providing rationale for derivation of water quality standards.	Comment is noted. This information is discussed in detail in the draft MCRP report, CHM report and groundwater modelling report. EPA and other relevant authorities/reference groups have been provided with these reports and are familiar with the potential risks associated with filling the mine pit void. The CHM document has been provided to Bluesphere and they have also attended the risk assessement discussions. The memo was developed to provide a snapshot of the framework to develop the water quality performance standards with a summary of baseline data. The contents of this memo will be incorporated into the overarching consolidated ash risk assessment report and will form a more cohesive discussion of risks, pathways and the CSM. Reference to the above documents can be made within the memo in the memo.	Noted
3	NA	Water Quality Standards and GED Overview		Paragraph 3 on page 1: In general this section is slightly confusing in that the discussion switches between surface water and groundwater. It would benefit from some clarification to make it clear when each is being discussed, and why both are relevant to the final development of water quality performance standards.	Comment is noted. This paragraph can be reworded.	Noted
4	NA	Water Quality Standards and GED Overview		Paragraph 3 on page 1: UEVF should be defined, as should its relevance to water quality in the mine water body.	Comment is noted. The relevance of mine water seepage to the upper sands of the UEVF will be discussed. The UEVF in connection with the water body is the unsaturated coal seam - Group A. The Basal Clay confines the lower UEVF. The upper UEVF is very low yielding and consists of approximately 120m clay/coal horizons. Refer to CHM for further detail on the geological CSM.	Noted
5	NA	Water Quality Standards and GED Overview		Last paragraph on page 1: For clarity note the segment of Central Foothills and Coastal Plains applies to surface water only. With respect to groundwater, this segment is only relevant to the environmental value of Water Dependent Ecosystems and Species.	Comment is noted.	Noted
6	NA	Water Quality Standards and GED Overview		The environmental values listed are for groundwater only. It is recommended that the environmental values of surface water are listed separately as they are not the same as those for groundwater.	Comment is noted. The mine water body is disconnected from the surrounding surface water system. Invert level of Lower Anglesea River is 4m AHD; the water body would have to fill to a greater elevation than this invert level to provide a mechanism with which discharge and interaction with the Lower Anglesea River could occur. Also, the consolidated ash is at -8 to -15 mAHD, which is far lower than the invert level of the River. February 2023 - in line with subsequent discussions the risk of overflow of the water body into the lower Anglesea River will be addressed for the MCRP	At a high level it is important to demonstrate that the water body will not present a potential risk to external environments, even if the likelihood of a release is very small. For example, in the unlikely event that overflow from the water body occur and the pH was sufficiently low, it could theoretically cause a fish kill event. The likelihood of this occur is very low, however, the consequence would be catastrophic. Whilst not specifically the focus of this review, justification that the adopted water quality standards would not compromise the external environment would be of comfort to the regulator, even if the likelyhood is very low.
7	NA	Water Quality Standards and GED Overview		Second paragraph on page 2, which discusses the applicability of environmental values as per the ERS. It should be clarified that where background water quality does not support an environmental value, the background water quality becomes the objective (Clause 19(2)). It would be beneficial to clarify the role of GED as per EPA Publication 1992: *"Circumstances where environmental values are not recognised in the ERS still must be managed in accordance with the general environmental duty (GED). This means that a person must still take reasonably practicable measures to minimise risks from pollution and waste to the environment or human health, even where environmental values may not apply in the ERS."*	Comment is noted. If background levels are naturally elevated, the system will be naturally adapted to those levels, and in this catchment there will be no risk of harm at those levels. For clarification we assume you are referring to Clause 16(2) not 19(2) of the ERS. Noted regarding the GED. The statement was made at the start of the memo to recognise Alcoa's general environmental duty. It is also the objective of the revised MCRP (to be developed) to address the minimisation of risks from the mine and water body features. Further text will be added regarding the wording from EPA Publication 1992.	Confirming reference to Clause 19(2), which relates to surface water. 16(2) relates to groundwater. There seems to be a difference in interpretation of the ERS in so far as whether environmental values apply when the background does not meet the generic water quality objectives. In the case of water dependent ecosystems and species, we are of the understanding that it will always apply (consistent with Alcoa's proposal to ensure the water body supports local flora/fauna), apart for those water bodies explicitally prescribed in the ERS.
8	NA	Water Quality Standards and GED Overview		First paragraph on page 3: It should be noted that it is EPA's view that the mine water body is regarded as an artifical lake and therefore is not subject to the exemptions stated in Clause 13(2) of the ERS (refer to letter of 24 March 2022). That is, the mine water body will have some environmental values depending on background water quality and the purpose for which the mine water body is intended. It should be noted that the Water Act 1989 also provides that water bodies should not be polluted with respect to any 'beneficial purpose' that they are reasonably intended to be used. This principal is consistent with application of environmental values and GED in this situation.	The objective of the mine pit lake is that it compliments surrounding natural catchments and environment. This is the development of a safe and stable landform. With native re-vegetation rehabilitation and a mine water body that is consistent with a background surface water quality which local ecosystems are naturally adapted to. It is acknowledged that Alcoa still have a GED, the Consolidated Ash Risk Management and Technical Assessment and the CHM all support this duty.	It is important to note that the proposal is protective of the environmental value of water dependent ecosytems and species consistent with the local catchment (e.g. background becomes the objective).
9	NA	Surface Water		A review of the references provided has not been conducted, however, it is understood that the acidity experienced in the lower Anglesea River is in part a result of human interference. This is of relevance when establishing natural background. Similarly, is there any evidence that human interference has affected natural background quality up-stream of the site?	We acknowledge that Bluesphere have not reviewed the references provided, however, this is not required for this particular document scope. In addition, there is no current or future predicted connection between the water body and Lower Anglesea River or indeed any surrounding surface water feature. The presence of potential and actual acid sulfate soils within Coogoorah Park can excarbate the Lower Anglesea River acidity during low flow but this is downstream of the water body. Historically the ash pond discharges to the River mitigated acidity by increasing pH and water flow, however, since this discharge ceased the River system is re-equilibrating to its naturally acidic nature. February 2023 - usbsequent discussions and edits to Section 4 have resolved this query	At a high level it is important to demonstrate that the water body will not present a potential risk to external environments, even if the likelihood of a release is very small. For example, in the unlikely event that overflow from the water body occur and the pH was sufficiently low, it could theoretically cause a fish kill event. The likelihood of this occur is very low, however, the consequence would be catastrophic. Whilst not specifically the focus of this review, justification that the adopted water quality standards would not compromise the external environment would be of comfort to the regulator, even if the likelyhood is very low.
10	NA	Table 1		For pH the 10th percentile should be calculated rather than the 90th percentile where the intent is to establish a natural background level as it is the lower end of the distribution that is of relevance for pH rather than the upper end (for this data set).	It is acknowledged that the background water quality of the water body (and surrounding catchment) differs from the objectives in the ERS. As specified in ERS the background water quality is the default objective under these circumstances. The indicators specified in the ERS have been selected to protect ecosystems with species that are sensitive to variations in the concentrations of these indicators. It is recognised that the water quality of the water body is a highly modified environment and the indicators selected to monitor the water quality should be indicative of this acidic environment. Minor ions (aluminium, boron, iron and zinc) are synonymous with surface water quality within the Anglesea catchment and aluminium, iron and zinc can contribute to changes in pH. Changes in pH can also affect the solubility of these metals and in turn affect the concentration of total dissolved solids. Therefore, these indicators are constituents of interest (COI) in the geochemical characteristics of the water body. In order to develop an environmental reference point for the water body, water quality performance standards will be calculated using the historical datasets for these COIs. A statistical approach will be adopted which will include using the 90th percentiles for the minor ions and TDS. For pH, the performance standard will be a range comprising the 10th and 90th percentile of the historical dataset.	Noted
11	NA	Mine Water Body		It should be acknowledged that the water quality in the mine water body will change overtime as the proportion of water inputs from various sources changes, and also due to geochemical and hydrodynamic reactions occuring within the mine water body.	Acknowledged, this is presented in the CHM report February 2023 - CHM report is referenced in Section 4	It needs to also denoted in this report.
12	NA	Table 3		The pH values reported to date in the mine water body are acidic. Has any geochemical investigation works been conducted to understand the reactions that are driving this? The drivers for specific water quality parameters should be clearly described as this is of relevance to demonstrating GED (i.e. are there reasonable and practicable measures available to alter such reactions occuring).	The mine water body is acidic due to the same geochemical reactions that influence the natural catchment acidity, oxidation of reduced iron sulfide minerals and hydrolysis of aluminium and iron species (manganese and zinc to a lesser extent). This is discussed in detail wihin the draft MCRP. The draft MCRP did also discuss water body amendment. At the time of drafting the MCRP (2017) connectivity to Salt Creek was proposed. This is no longer proposed and amendments are no longer being discussed. These discussions will be removed from the revised MCRP (in development).	Noted
13	NA	Table 3		It has been noted that boron is elevated in the mine water body compared to up-stream water quality and groundwater. This is significant as natural ecosystems in the area are unlikely to have necessarily adapted to this level of boron. This will need further consideration with regard to potential risk to water dependent ecosystems and species, GED and BATT.	Not with standing the non-connectivity between the water body and surrounding surface water systems, the presence of boron in soils and surface water has been risk assessed. EHS Support (2021) Supplemental Surface Water and Soil Investigation Report has been provided for context of boron presence in the catchment. February 2023 - elevated boron in the water body in comparison to the surrounding catchment is now discussed within the report	This does not appear to have been contemplated in the report. It would seem an important point.
14	NA	Proposed Water Quality Standards		The first paragraph does not appear to align with the proceeding sections (refer to Comment 7). The specific environmental values that are to be protected should be stated. Similarly, rationale should be provided as to why the other environmental values of surface water for the catchment are not applicable.	Under the ERS the relevant EV to be protected are catchment specific. However the water body is an artificial feature and EV do not apply. In addition there is no connectivity to the surrounding surface water catchments, so the EV that apply to the surrounding surface water systems do not apply to the water body. February 2023 - subsequent edits have included the acknowledgement to protect relevant EVs	Noted
15	NA	Proposed Water Quality Standards		Performance standards are proposed to be developed based on 10th and 90th percentiles. Rationale should be provided for this approach given that the ERS adopts 25th and 75th percentiles.	EPA put forward the 10th percentile for pH and also agreed to the use of 10th/90th %ile for deriving performance criteria (EPA letter dated 02/09/2022).	This should be clearly stated so that its basis is shown to have been agreed.
16	NA	Proposed Water Quality Standards		It is understood that the environmental performance standards are to be derived from statistical assessment of monitoring data for the mine void. Is such an approach inherently biased in that it is based on the water quality as it occurs rather than the water quality to be achieved? Further it is anticipated that the water quality will change over time; use of percentile based statistics assume the data oscilate around a value of central tendency.	The aim of creating a safe and stable landform does not include the modification of the water body quality. Water quality will vary over time, however, the water quality will not deteriorate outside of the performance targets derived from the statistical assessement. This will be supported by limnological modelling, to be provided in the revised MCRP (in development).	Noted
17	NA	Proposed Water Quality Standards		Further to comment 15 above, with regard to GED, it is understood that the key risks associated with water quality in the mine water body are: a) Potential impacts to water dependent ecosystems and species that are not adapted to natural background conditions in the catchment; and b) An uncontrolled release to the down-stream environment (e.g. in the event of an extreme rainfall event). c) Potential risks to down-gradient groundwater receptors prior to the establishment of the mine body as a permanent groundwater sink. To that end, it is considered that the background water quality in the Angelsea River down-stream of the site should also be considered and may in fact provide a more appropriate performance measure. In addition, consideration should be given to a separate set of perfrormance measures that are designed to prevent potential risks to off-site groundwater receptors.	We are not entirely sure what this comment is trying to convey: a) are Bluesphere referring to ecosystems in the mine water body or ecosystems associated with discharging groundwater to surface water systems? b) the likelihood of this occuring is very small. Preliminary modelling indicates a recovery level of the water body at around 5m AHD. Overtopping could potentially occur at approximately 10 mAHD, which would require about 4 GL of water to increase the level by 3 m. Given the volume of water required for this to happen, the fact that the mine water quality is similiar to the catchment and that significant dilution would occur with that much rainfall, we consider the risk to be low. c) the preliminary modelling shows that it is not an issue. Refer to CHM. Modelling indicates, short-term, that radial flow from the water body up to 100 m into the DBF and BF before flow reversal back to the water body occurs. Long term the water body is a discharge feature and is not connected to catchment surface water.	At a high level it is important to demonstrate that the water body will not present a potential risk to external environments, even if the likelihood of a release is very small. For example, in the unlikely event that overflow from the water body occur and the pH was sufficiently low, it could theoretically cause a fish kill event. The likelihood of this occur is very low, however, the consequence would be catastrophic. Whilst not specifically the focus of this review, justification that the adopted water quality standards would not compromise the external environment would be of comfort to the regulator, even if the likelyhood is very low.
18	NA	Proposed Water Quality Standards		It is stated that contingency measures will be established to take into account seasonality. Note the use of percentile based statistics are designed to take into account this variability. Further elaboration of what would constitute a contingency measure should be outlined.	The reference to seasonal changes was added as an example, however, will be removed to avoid confusion. Contingency measures will be developed as part of the risk assessment process.	Noted
19	NA	Proposed Water Quality Standards		The second paragraph on page 9 outlines that a risk assessment will be conducted with respect to human health. Please elaborate on what type of risk assessment will be applied, e.g. quantitative human health risk assessment in accordance with the ASC NEPM, or another approach.	Qualitative risk assessment process, refer to Chapter 9 of the consolidated ash risk assessment doxcument which will be provided in the next few days. HH risk assessment will only be conducted if the current risk assessment process indicates there is a risk to HH. The water body is not to be used for human based activities and also there is no ingestion pathway for humans.	Noted
20	NA	Proposed Water Quality Standards		Will geochemical and hydrodynamic modelling be undertaken to predict the likely water quality once the water balance for the mine void is established? This will provide a useful benchmark of expected water quality which monitoring data can then be assessed against.	Limnological modelling is proposed as future work but not necessary for this memo review.	Noted
21	NA	Conclusion		The conclusion should recognise that there are some environmental values that are relevant to the mine water body (refer to Comment 7).	We do not agree with this comment. We suggest further discussion with Bluesphere so they can state which EVs they feel are relevant and justify why they think they are relevant. February 2023 - BlueSphere comment has been acknowledged in subsequent report updates	It is our view that the water body will have some environmental values, those being water dependent ecosystems and species consistent with local background and water-based recreation (aesthetic enjoyment) (i.e. presumably the public will be able to view the lake and it should not be offensive to the senses).
22	NA	Conclusion		The second paragraph discussed the salinity of the groundwater. It is not clear how this relates to the water quality performance standards.	The second paragraph talks about the TDS of UEVF and how it relates to the segment of groundwater and the relevant protected environmental values. We suggest removing reference of the UEVF (below the Basal Clay) and provide more relevant discussion on DBF and BF groundwater quality.	Noted

Consolidated Leached Ash Technical Risk Assessment

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (9 December 2022)	Assessor's Response (Date)	Reviewer's Comment (12 January 2023) following workshop	Report Revision	Reviewer's Comment (10 May 2023) following receipt of Final Report	Assessor's Response (7 June 2023)	Report Revision	Auditor's Comment (9 June 2023)	Reviewer Close Out (Y/N)
1	General		Draft	We note that this document is a consolidation of works that has been previously reported separately, including Document 1, Document 3 and Document 4. Comments previously provided on those documents are therefore considered relevant to the content of this document. To that end there seem to be a number of examples where appropriate responses have been provided in previous IRRs but are not reflected in the report.	We thought these had been all addressed but will check previous responses to ensure agreed responses have been enacted	TBC	Final	ok	No further action			Y
2	1.2		Draft	The opening sentence needs to be broader and address current, and particularly future scenarios (namely the submergence of the ash in the pit lake). As written, seems to apply only to present day.	We will make changes to address this comment Completed	TBC	Final	ok	No further action			Y
3	1.2		Draft	Paragraph 3: indicates a conclusion of low risk from the risk assessment. It would be useful to briefly refer to whose risk framework is being adopted in terms of materiality of consequences etc. Is this an internal Alcoa framework, or something adopted from the regulatorls or Australian Standards.	The RA is an ERR process framework - also refer to comment 31. Will make reference to the ERR process Incuded	TBC	Final	ok	No further action			Y
4	1.2		Draft	Paragraph 4: replace "BlueSphere Consultants" with "BlueSphere Environmental Pty Ltd"	Agreed Completed	TBC	Final	ok	No further action			Y
5	1.2		Draft	With respect to EPAs queries in Table 1-1, we perceive some potential gaps in the work completed or proposed. These are in relation to monitoring of short and long term cap performance. Namely, there may be a gap in the groundwater monitoring network in the vicinity of the CLA to monitor short to medium term performance as the lake fills (i.e. a lack of groundwater bores in the immediate vicinity of the CLA to verify modelling predictions as the CLA is inundated). It is acknowledged that these wells would be eventually lost to the developing water body. Secondly, we think some additional monitoring of cap integrity could be proposed once the CLA is submerged (i.e. bathymetric survey to monitor any changes in cap morphology over time).	We believe that we have a robust network of shallow groundwater wells already established which are appropriately spaced around the water body to monitor water quality changes over time in both the fill material and the DBF. The majority of these wells are dry (except DBG MB6). Installing additional shallow wells in the vicinity of the CLA is also not considered warranted as the modelling predicts limited saturation of the ash material prior to inundation over the CLA area, thereby there is no mechanism for transport of CLA pore water (if this does occur). In support of this is the validation of the clay capping of extremely low permeabilities of 10-9. So based on the numerical model response to rising groundwater levels, is there any point in having monitoring locations in the vicinity of the CLA if the fill material remains unsaturated even when surface inundation occurs? Particularly when the wells would be temporary due to inundation, and also then would present a potential migration path risk in and of themselves. There are erosion control measures in the risk assessment that have been proposed. Unless the erosional risk is considered high, then why would surveying be considered warranted - this said does Bluesphere have any experience in underwater bathymetric surveying that you could share? No additional commiments to monitoing as supported by BlueSphere discussion and response (cell G20)	As discussed, even dry wells in the vicinity of the CLA could verify the modelling predictions and conceptualisation in the short term. However, we do acknowledge the presence of existing groundwater bores at the periphery of the mine void. As discussed, we propose to endorse the concept that future groundwater monitoring is required and will be undertaken without commentary on the appropriateness of the network, frequencies and other details as those will be documented in a subsequent monitoring plan. The regulator may perceive that the existing wells are too far away to monitor specific impacts from the CLA.	Final	We agree that it has been demonstrated that risks of excursion of solutes from the CLA to the surrounding fill material is low based on permeability testing and modelling, particularly in the short term where it is expected that the CLA and surrounding fill will remain unsaturated. However, monitoring of expected performance is still considered to be a reasonable expectation of the regulators and it is our view that the existing bore network at the periphery of the mine void is unsuitable to detect any specific impacts from the CLA, particularly in the short term. We acknowledge that any wells installed at the periphery of the CLA will eventually be lost to the developing water body. It is further acknowledged that any such wells would need to be appropriately decommissioned prior to lake encroachment; however, it expected that any wells would be within the fill material suorrounding the CLA and not within the CLA itself.	Following discussion with BlueSphere, it is agreed that the risk assessment of the CLA area is restricted to the activity of CLA inundation. Under the accelerated fill water strategy, this will be in the order of 2 years. Due to the inundation of the CLA area, the existing network of monitoring wells screened within fill material (DBG MB4, DBG MB5 and DBG MB6) are located as close to the CLA area as practicable and are considered appropriate to measure impacts from the CLA area during the activity of inundation and after the void is filled.The locations have been selected in accordance with safety and stability constraints and cultural heritage sensitivity. Section 1.2 additional text: *Groundwater monitoring wells are located in the vicinity of the CLA area (DBG MB4, DBG MB5 and DBG MB6) and are screened within the clay -rich fill material. These locations have been part of the groundwater monitoring network surrounding the mine area since 2021 and will continue to be monitored as the CLA area is inundated by the water body.* Section 4.8 additional text: *It is acknowledged that in order to verify the assumptions within this report, that groundwater monitoring should be conducted in the vicinity of the CLA area to assess whether pore water migration from the CLA area is occurring. Sentinel wells located in proximity to the CLA area (within 5-10 m) were considered, however, this was not considered practicable for the following reasons:* *•Based on the conditions encountered during the two phases of site investigation in 2021 and 2022, the condition of the ground in the vicinity of the CLA area is uneven and at times saturated making drill rig manoeuvres* ***a significant safety issu****e. Now, 9-10 months on from the last field event, the water body elevation has increased further and is even closer to the CLA area.* *•The process of inundation is potentially within a time period of 2 years, during which wells will need to be decommissioned prior to submergence. This does not provide an adequate time frame to collect a representative dataset as the formation surrounding the CLA saturates.* ***Further the objective of these wells would be to validate any potential seepage from the CLA, and this can't occur if the area is submerged.*** *•Based on the* ***SEEP/W*** *model outcomes the formation may remain unsaturated after inundation, meaning that there will be no groundwater quality to measure.* *Therefore, existing groundwater monitoring wells in the vicinity of the CLA area (DBG MB4, DBG MB5 and DBG MB6) will be used to monitor the potential risks of pore water migration from the CLA area into surrounding fill material during (and after) the inundation period. These wells are screened within the clay -rich fill material and DBF and BF. These locations have been part of the groundwater monitoring network surrounding the mine area since 2021 and will continue to be monitored as the CLA area is inundated by the water body. Due to their locations they will remain even after the water body attains steady-state elevations.* **Monitoring/sampling of the mine pit water body will be undertaken during the filling period and inundation period. Evaluation of the results against WQPT will be used to evaluate whether seepage is occurring from the CLA.**	Final	ok	Y
6	4		Draft	Paragraph 1: refers to "interim" WQPS. May need to explain what is meant by interim, and when/how the final WQPS will be established.	Interim WQPS can be developed based on the current dataset. These could be progressively updated as the dataset increases as monitoring progresses. Final WQPS will be developed when the water body is at steady state or final elevation.	Resolved during discussion. It is understood that this terminology will change.	Final	ok, it is clearer now why interim is being used. We understand there is a framework for developing the final WQPTs, in which the MCRP will require both the filling strategy to be finalised and the development of the final WQPTs.	Refer to response to Item 23. No further action	Final	ok	Y
7	4.1		Draft	Third last paragraph on page 9, refers to environmental values not applying to artificial features. It should be noted that the water body will however need to be protective of flora/fauna support consistent with the local catchment conditions, that is, the environmental value of water dependent ecosystems and species is a protected environmental value.	Can you further clarify that you agree with the commentary around artificial assets, as described in the ERS and as previously agreed with the EPA. Alcoa recognise their responsibilities in accordance with the GED, which includes the protection of relevant environmental values, e.g. water dependant ecosystems and species. However it is stated that the WQPS are based on the baseline water quality of the pit. This baseline sets the benchmark for the protection of interconnected catchment ecosystems that are water dependant. It is further acknowledged that these ecosystems already have adapted to the acidic conditions of the existing surface water systems and catchment.	Resolved during discussion. It is understood that WDES and Aethetics will be considered applicable EVs.	Final	ok, WDES and Aethetics now acknowledged for the water body. Please check wording on aesthetics for off-Site receptors.	Wording has been edited in Table 4-1 and Table 4-2 for off-site receptors (EV-WBR)	Final	ok	Y
8	4.1		Draft	Further to the above, there are a number of instances where it is stated that environmental values do not apply to 'artificial constructed features'. As per previous comment 8 regarding Doc 4, this contrasts with EPA's advice of 24 March 2022. It is our view that it should be acknowledged that the water body will have some environmental values, those being water dependent ecosystems and species and water-based recreation (aesthetic enjoyment) (i.e. presumably the public will be able to view the lake and it should not be offensive to the senses).	In 24 March 2022 EPA comment that they consider artificial lakes to have environmental values, however they acknowledge that there may be local constraints that cause difficulties in protecting all environmental values, therefore these should be considered when setting environmental values. Our position is that MoE is the only relevant environmental value applicable to the artificial lake. Clarification from EPA: For ecosystems the background levels should be adopted by default (regardless of whether they are less than or exceed the objectives in Table 5.4 of the ERS) refer ERS Section 16 cl(2) The final MCRP will address the catchment water balance, which is not the objective of this document. The overall MRCP objective is that the pit is a safe and stable landform. As previously agreed with DELWP (and documented in the draft MCRP - Sept 2017) it states that there are no environmental values related to recreational use (i.e. boating, swimming). Aesthetic enjoyment is also subjective. It is not the intention or expected to create a feature that is offensive to the senses. Aesthetic (or passive recreational use of water bodies) refers to nuisance organisms such as algal growths. This could be addressed in the MRCP. We refer back to the objective of this work, which is solely related to the submergence of the CLA.	Resolved during discussion. It is understood that WDES and Aethetics will be considered applicable EVs.	Final	ok	No further action			Y
9	4.2		Draft	Paragraph 3: notes the identification of "several key hazards". It is important to document by what process these hazards were identified, in order to provide some surety as to the completeness of the list. We understand a workshop was convened with a group of internal/external experts - this process should be summarised.	Agree - the process (ERR risk assessment process and framework) is described later in Section 10, but will review and address the wording to ensure this is clear. Additional text added to Section 4.2	ok	Final	ok	No further action			Y
10	4.3		Draft	With respect to the disconnection between the UEVF (basal sands) and the water body due to an upward gradient existing, please clarify if this also applies, or is likely to apply, once the water body is established.	Once the water body is established and reaches steady state, the water body will act as a groundwater sink. This includes groundwater movement from the UEVF to the water body. This is supported by numerical modelling undertaken in 2017 and 2019 and preliminary modelling using the revised Anglesea Groundwater model which has been deemed fit for purpose by an independent technical review panel (appointed by DELWP). Further, analytical modelling (using the laboratory derived parameters of the basal clay) suggested that during the filling of the water body the level remained 2m higher than the groundwater level and it would take about 7 years for any pressure impacts to migrate through 2m of Basal Clay. Note: During the 6-month UEVF pumping test when the hydraulic gradient was extreme (65m head difference) between the pumped bore screen and the overlying units, no drawdown or change in trend was observed in any overlying units (including those immediately overlying the pumped unit). This gives an indication on the competency of these clay layers between the thin sands of the UEVF. Above text added to report	ok	Final	ok	No further action			Y
11	4.3		Draft	Table 4-1 and 4-2: Please provide a reference for where this data is sourced. Did Alcoa collect this data? It would be useful to provide a statement on the data quality.	Check Paragraph added to provide detail on QAQC and sample collection	TBC	Final	ok, still a little unclear where the surface water data is from. IPR report will note that no independent review of QA/QC protocols has been undertaken.	There has been a change to Table numbering so we assume this comment now refers to Tables 4-4, 4-5, 4-6, 4-7 and 4-8. The data has been collected from monitoirng locations AV2, SV2, MB1 through MB7, MW002, MW008, MW014, MW015, MW016, MW018, MW020, MW021, MW022, MW023, MW024, MW025, MW026, MW027, MW029, MW030, MW031, MW032, MW033, MW034, MW038, MW050, MW052, MW059, MW060, MW062, MW064, MW066, MW069, MW072 and MW073 and finally the water body. The DBG and DBF bore locations have been added to Table 4-7 (as a footnote). QAQC samples have been collected for the UEVF and DBG/BF GMEs. Water body samples are usually singular so no associated QAQC and QAQC has not been conducted on historical sampling (prior to 2015).	Final	ok	Y
12	4.3		Draft	Table 4-3: further to comment above, where is this data sourced and what spatial area does it represent? Is this site-derived or regional data?	Check Edit provided which confirms site location of UEVF basal sand bores	TBC	Final	ok	No further action			Y
13	4.3.1		Draft	Table 4-4: Some of the aluminium numbers seem very high - these appear to be total analyses, rather than filtered samples. Please clarify. Is it possible that some of these data are skewed high by entrainment of particulate matter in unfiltered samples?	Check Observation is correct and data has been reviewed and replaced with dissolved analysis. Clarification sentence added	TBC	Final	ok	No further action			Y
14	4.3.2		Draft	Paragraph 1: replace "recharge" with "discharge"	Editorial Corrected	TBC	Final	ok	No further action			Y
15	4.4		Draft	First sentence: clarify that 10th percentile used for pH	Check	TBC	Final	ok	No further action			Y
16	4.4		Draft	Suggest Tables 4-6, 4-7 and 4-8 be merged together so that it is easier to compare data between the various materials.	Check New tables 4-7 and 4-8 compare all locations together for 90th and 10th percentiles	TBC	Final	ok	No further action			Y

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (9 December 2022)	Assessor's Response (Date)	Reviewer's Comment (12 January 2023) following workshop	Report Revision	Reviewer's Comment (10 May 2023) following receipt of Final Report	Assessor's Response (7 June 2023)	Report Revision	Auditor's Comment (9 June 2023)	Reviewer Close Out (Y/N)
17	4.4		Draft	The analysis presented here is contingent on the current mine water body quality being acceptable and therefore an appropriate benchmark. Under the fast fill scenario, the water body is expected to be comprised largely (initially at least) of water derived from the UEVF. As such some comparison to the existing quality of that water may also be instructive. Ultimately, it is our view that the most appropriate benchmark is one that representsfis protective of the background surface water quality within the local catchment (i.e. Salt Creek and the Anglesea River) as then it can be argued that the proposal will not preclude the environmental value of water dependent ecosystems and species consistent with the local catchment. The water body water quality is an amalgam of sources, including anthropogenic sources. As such the water quality of the water body is considered to be an arbitrary benchmark and difficult to justify externally. It is a much easier argument to utilise the background surface water quality as the benchmark and we expect the regulators to view this similarly.	There is currently no approved water filling strategy and there is no agreed surface water connectivity between the water body and surrounding surface water catchment. The water filling strategy is subject of separate parallel works as you are aware related to potential for UEVF groundwater. However the over-riding objective is that the water quality will not be worse than it currently is in the water body and the surrounding catchment. In the future additional assessments may be undertaken to evaluate risks to flora/fauna (toxicological surveys) based on the finally agreed water source, however this is an issue for the longer term MRCP (which is expected to include appropriate limnological or similar modelling for long term water quality). First point: No protection required as the pit and the surface water systems are disconnected. Our baseline is the water quality in the artificial water body. Second Point: Environmental value of MoE is acknowledged in relation to the pit, however the water quality performance indicators are already exceeded. Alcoa are evaluating risks to ecosystems through the GED framework (i.e. modelling etc). Ecosystems in the catchment are already adapted to water quality conditions similar or comparable to that of the mine pit. Based on the baseline conditions in the UEVF the water quality is not expected to change significantly from that that exists in the pit now. It is acknowledged that there will be reactions/changes due to oxidation/dissolution. UEVF is an anaerobic system although when discharged to the water body it becomes aerobic and water chemistry will change.	Resolved during discussion. It is understood that catchment background will be adopted.	Final	We acknowledge the decision to retain the existing mine pit water quality as the basis of Interim WQPTs and the reasons given for that decision. With the context that has now been provided, namely that (a) the WQPTs are interim until a filling strategy is finalised, (b) they are intended to relate only to localised impacts from the CLA on the water body and groundwater (and not broader pit lake water or groundwater quality issues), and (c) they are comparable with background catchment water quality with the exception of boron, which has been qualitatively assessed as likely to pose a low risk to relevant receptors, we are of the opinion that the interim WQPTs are appropriate for their intended purpose. Please check 90th percentile for TDS - it is higher than the reported max.	Updated equis report for the water body. 2021 to 2022 used for table as the more recent data has associated QAQC.	Final	ok, our final position on the boron issue will be articulated in the ITPR letter, which is that if final WQPT propose a boron concentrations above catchment background, then a quantitative ecological risk assessment should be conducted to confirm risk to ecological receptors are low and acceptable.	Y
18	4.5		Draft	Paragraph 2 asserts that the naturally occurring background water quality in the DBF&BF exceed the relevant objectives and that as a result the relevant environmental values cannot to be achieved. Where is this established and is it true of all analytes at all locations?	*DSI (April 2021) EHS Support. Section 10, Appendix R,S,T.* states that background (based on a number of relevant located wells) concentrations of Al, Ba, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Zn and TKN exceed Tier 1 screening criteria for one or more protection environmental values, based on Segment B classification. The Power Station is currently under Audit, all works completed in accordance with auditor approved Plans. Above text added	ok	Final	ok, text appears to have been removed.	Agreed, no further action				Y
19	4.5		Draft	Table 4-9: If zinc is a key indicator of ash leachate impact, then a WQPS should be included for it for the DBF&BF. An appropriate background level for zinc in the DBF&BF may need to be established through sampling (i.e. in the power station area), if it is not currently known.	Acknowledged that Zn analysis is limited. This was an oversight and Zn is now included in analytical suites.	ok	Final	ok	No further action				Y
20	4.5		Draft	Paragraph 5 states that WQPSs "will be developed…". Please clarify if both interim and final WQPSs are envisioned and if so, how and when the latter would be derived and applied. Perhaps the terminology should be modified to differentiate between long-term WQPS which are yet to be derived, and Consolidated Leach Ash Water Quality Performance Standards?	The focus of the WQPS memo is to monitor and evaluate potential impacts associated with the CLA. The setting of criteria is based around this objective. The initial standards (or interim) will be developed based on the baseline dataset as data is collected during the development of the water body as the baseline is likely to change dependant on the source of water. Therefore final standards may be different from the interim, but the changes will be solely related to the source of water. Additional water quality parameters (or indicator parameters) may be needed to differentiate between the water types	Resolved during discussion. It is understood that catchment background will be adopted as the basis of the WQPS and the terminology with respect to interim and final will be amended.	Final	ok, it is now clear that they are interim.	Refer to response to Item 23. No further action	Final	ok	Y
21	4.5		Draft	How will the these proposed WQPSs for the mine water be achieved in the long term? As described the lake will be a terminal discharge feature with no out let to the surrounding environment. Will solutes not accumulate in the water body under this scenario? We note that this comment is outside the scope of our review and presume that this issue will be (or has been) addressed through water balance studies, hydrological modelling and/or limnological studies.	Comment is acknowledged. Note that the final MRCP will incorporate the full cycle water balance, whether that is in the form of geochemical modelling, that is yet to be confirmed.	ok	Final	ok	No further action				Y
22	4.6		Draft	First paragraph, refer to comment 8 above and not which environmental values are to be protected. Suggest the second paragraph be re-worded so its context is clear. An introductory sentence would be beneficial to give context…	Check More detail surrounding the preclusion of environmental values has been added to Section 4.1. In addition why most Evs are considered either irrelevant or unsupported…	TBC	Final	ok	No further action				Y
23	4.5		Draft	The mine water quality standards are based on existing water quality in the mine pit. With a fast fill strategy, the water quality would trend toward the UEVF, which would expect to result in a reduction in TDS, Al, B, Fe and Zn concentrations overtime. This would in essence, act to offset any increases in contributions from the CLA. To that end, it would seem that even if porewater from the CLA reached the waterbody, it would be unlikely to be measurable within the context of long-term water quality change occurring in the water body. The standards therefore really only provide an indication of a	The modelling indicates that there is no impact from the CLA. We believe we have demonstrated that there is no CLA pore water emission to the water body based on a fill material permeability of 10-6 m/sec. Fill material median permeability is 10-9 m/sec. TDS is unlikely to change significantly i.e. metals/solids will not drop out but are expected to remain in solution. We agree with the second paragraph although as mentioned above modelling indicates that this will not occur.	ok	Final	As discussed, modelling is a predictive tool that does not obviate the need for monitoring to confirm predictions and assumptions are holding true. It is understood that the finalisation of the filling strategy will prompt the derivation of the final WQPTs, which will need to consider these issues at the appropriate time.	Noted and this statement has been added to Section 4 and Section 11 (the Interim Water Quality Performance Targets and Summary and Conclusions): *It is important to note that the long term WQPTs for the mine water body cannot have not been determined at this time as the mine water body filling strategy has not been finalised. Interim WQPTs have been developed and are included within this assessment. Final WQPTs, these are expected to be included as part of the MRCP (when finalised).*	Final	ok	Y
24	4.5		Draft	It should be stated that the water quality standards are consistent with the background water quality in Salt Creek and the Upper Anglesea River, and therefore the environmental value of water dependent ecosystems and species (that are consistent with the local catchment) would be maintained. This is important as it makes clear to the regulator that this process does not result in a sub-optimal environmental outcome so far as the protected environmental value of water dependent ecosystems and species is concerned.	They are comparable (not consistent) to the surface water catchment, however the environmental values of the surface water systems are not relevant for the evaluation of potential CLA seepage into the pit. The presence of the water body is not going to degrade the surrounding disconnected surface water catchment or the associated environmental values.	Resolved during discussion. It is understood that catchment background will be adopted as the basis of the WQPS.	Final	ok, see Item 17 response	Updated equis report for the water body. 2021 to 2022 used for table as the more recent data has associated QAQC.	Final	ok, see Item 17 response	Y
25	Table 5-2		Draft	The rationale for the adoption of the 5,000 ppm saline solution as agreed should be provided.	Update Footnote 21 expanded to include rationale behind value	TBC	Final	ok	No further action			Y
26	6.3.3		Draft	As per previous comments, if the fast fill scenario is enacted, the water chemistry in the water body is expected to trend towards that of the UEVF, at least in the short term. How would the analysis in Table 6-8 look with the water quality from the UEVF included?	Please refer to Item 17 response	Resolved during discussion. It is understood that catchment background will be adopted.	Final	See Item 23 response	Noted and this statement has been added to Section 4 and Section 11 (the Interim Water Quality Performance Targets and Summary and Conclusions): *It is important to note that the long term WQPTs for the mine water body cann ot be determined at this time as the mine water body filling strategy has not been finalised. Interim WQPTs have been developed and are included within this assessment. Final WQPTs are expected to be included as part of the MRCP finalisation.*	Final	ok	Y
27	7.2.1		Draft	As per comments provided on Document 3, the last paragraph states that impacts from LA water discharge and infiltration did not appear evident in the discharge area; however, there are some substantial differences reported between analyte concentrations in this area and the reference clay-rich cover, particularly at ADBH32 (Na, Cl, SO4, Fe etc.). Is this attributed to heterogeneity in the fill material or evidence of impact? The nature of the analytes (particularly Cl) suggests a possible interaction with ash leachate, rather than a geological origin.	We have discussed the heterogeneity of the fill material, however, we acknowledge there may some limited impact. However it does not change the overall outcomes of the risk assessment. Accept last sentence.	The limited impact should be denoted as discussed.	Final	ok, the acknowledgement added to 7.2.2 should also be added to the end of 7.2.1 as the impact is also evident in the initial samples.	As suggested the acknowledgement has been added to the end of Section 7.2.1.	Final	ok	Y
28	9.1		Draft	The introductory sentence does not appear to be necessary.	Agreed and removed	TBC	Final	ok	No further action			Y
29	9.2		Draft	Note that much of this material is a repeat of information now presented earlier in the document, due the consolidation of previously separate reports. Consider amending.	Agreed and removed section	TBC	Final	ok	No further action			Y
30	9.5.3		Draft	The conceptualisation of the UEVF being a confined aquifer under artesian pressures in the vicinity of the mine void warrants some further discussion. We understand that the DBF&BF are unsaturated in the vicinity of the mine void currently, and that the UEVF is exposed within the mine void (at least to the extent of the coal seam, which marks the top of the UEVF, having been mined out historically). This raises the question as to how groundwater currently enters the mine void (apart from that from the pumping trial) and if it is derived from the UEVF, why the pit lake would not eventually reach the pre-mining artesian levels. We note that this comment is outside the scope of our review and presume that this issue will be (or has been) addressed through water balance studies, hydrological modelling and/or limnological studies.	We agree that this comment is outside the scope of the study but we have provided some additional commentary below. At steady state evaporation will be the primary water loss mechanism from the water body. Further, the artesian heads of the UEVF were found in the basal sand lenses. Drilling in the 1950/60 found evidence of lithostatic pressure (i.e. as you drilled through each coal and clay seam, the pressure would spike). The basal sand lenses are under a lot more pressure than the shallower sand seams. DELWP appointed an independent technical review panel consisting of expert modellers, ecologists, acid mine drainage and groundwater engineers. Their review concluded that the conceptualisation and revised Anglesea Groundwater model is deemed fit for purpose, with one of the objectives of the model being to understand pit water/groundwater interactions. Text added to report	ok	Final	ok	No further action			Y
31	9.6		Draft	As per previous comments, please state that the risk management framework is a DELWP/EPA/regulator-based risk framework. This adds substantial weight to the process used, and goes to the appropriateness of the likelihoods and consequences considered.	Refer to comment 3 Reference provided but inserted to Section 9.5 as numbering has changed with the deletion of Section 9.2	TBC	Final	ok	No further action			Y
32	9.7.1		Draft	Figure 9-8: Potentiometric surface level shown in the UEVF is substantially lower (-45 mAHD) than that stated in the text of Section 9.5.3 (-20 to -16 mAHD). The apparent similarity between the levels in the Fill and the UEVF also raises the question as to the origin of the water in the fill and the water body and the confined nature (or otherwise) in the UEVF in the vicinity of the mine void. We note that this comment is outside the scope of our review and presume that this issue will be (or has been) addressed through water balance studies, hydrological modelling and/or limnological studies.	We agree that this comment is outside the scope of the study but we have provided some additional commentary below. Refer to previous comment. In addition, there was a pumping test occurring in a confined aquifer with relativity low storativity and the potentiometric surface changes dramatically as a response to pump cycles. GWL symbol removed from figures 9-8, 9-9 and 9-10	ok, please check representatioon of the UEVF water level and update if needed. Currently Fig 9-8 indicates a strong downwards gradient between fill and UEVF	Final	ok	No further action			Y
33	9.8		Draft	An introductory sentence is needed to give context to the calculation, i.e. why is the calculation being undertaken and to what end?	Agreed sentence added to Section 9.7 as numbering has changed with the deletion of Section 9.2	TBC	Final	ok	No further action			Y
34	9.10		Draft	Table 9-4: It is not clear how the area of 2,160 m2 for the area of the leached ash has been derived or if this an input to the model. It appears to be an error based on the dimensions provided.	4.6ha? Check 7.0 to 4.6 ha values This was a carry over error and has been corrected to 4.6ha in the table. It has no significance on model outcomes as this value is not used in the numerical moelling only the preliminary conceptualisation	TBC	Final	ok, check final number (4,600 m2 = 0.42 ha). May not be significant	Value amended to 46,000 m2. Change does not impact on the model outcomes.	Final	ok	Y
35	9.11		Draft	We note that some elements of the watertable development predicted in these simulations is considered unlikely to occur in reality. For example they appear to be partly an artefact of the eastern boundary condition providing water to the model more rapidly than the model can effectively transmit, which is unrealistic for the eastern BC as it is the same material at and beyond the boundary as it is in the model domain itself. This is also possibly emphasised by the lack of any modelled flux upwards from the UEVF or incident rainfall, which would also provide water to the model.	The eastern BC is the boundary between the fill material and an unconsolidated natural lithology. The fill material has been compacted and has a higher component of clay. As discussed above leakage from the UEVF is unlikely even though the pressure head is vertically upwards. There is a net loss of water from evapotranspiration, so incident rainfall was not included within the model as discussed within the report. Above text added to report	ok	Final	ok	No further action			Y
36	10.1		Draft	Similar to previous comments, some of the material presented here is a repeat of text included in earlier sections. Consider amending.	Agreed and text has been refined to just reference to risk assessment assumptions and process	TBC	Final	ok	No further action			Y
37	10.1		Draft	Key assumptions may also need to include that the leached ash and encapsulating material remains geotechnically stable and intact during and post establishment of the pit lake and that the cap material in particular is unimpacted by the effects of bioturbation, wave action, settlement and a range of other potential physical, biological and chemical processes.	Agree	ok	Final	ok, we acknowledge the additional assumptions; however, we would prefer the wording in relation to geotechnical stability also included the leached ash and encapsulating material. Current wording appears to exclude it (i.e. "*the landforms surrounding the CLA*"). We consider that any affects of differential hydrostatic pressure on the CLA during inundation is a geotechnical matter and is not being considered here. We therefore need a clear statement that we assume these pressures will not deform or otherwise undermine the integrity of the CLA cap.	This bullet point has been edited to include reference to the CLA area in addition to the surrounding landforms	Final	ok	Y

Item	Section No.	Section Heading	Report Revision	Reviewer's Comment (9 December 2022)	Assessor's Response (Date)	Reviewer's Comment (12 January 2023) following workshop	Report Revision	Reviewer's Comment (10 May 2023) following receipt of Final Report	Assessor's Response (7 June 2023)	Report Revision	Auditor's Comment (9 June 2023)	Reviewer Close Out (Y/N)
38	10.2		Draft	Reference is made here to an Appendix K - Anglesea Mine Ash Assessment, but this is not enclosed with the Appendices provided.	Agreed Now attached as Appendix H	TBC	Final	ok	No further action			Y
39	10.2		Draft	Element 1 receptors at risk include the Anglesea River. It is unclear how this could occur during filling (or afterwards) given the absence of an outlet or connection. Please elaborate on the scenario being contemplated here (i.e. loss of containment during extreme weather or other event)	The receptor is considered as part of the risk process. We included this for completeness in the risk assessment even though there is no real potential likely pathway, really as this may be a question that we anticipate is asked by the regulators as part of their review.	ok, agree it should be considered. Future connection may be highly unlikely, but not impossible.	Final	ok	No further action			Y
40	10.2		Draft	There would seem to be a number of additional risk sources not accounted for in this list. For example, degradation of the capping materials over time through biological processes once the pit lake is established.	What biological processes are you referring to, bioturbidation?	Yes, the burrowing of aquatic organisms during and post lake establishment would be one example of such a potential process. As discussed, the long term presence of the 1.0 m cap would be expected to mitigate this risk; hence the relevance of monitoring its integity periodically (e.g. through bathymetric survey).	Final	ok	No further action			Y
41	Table 10-3		Draft	Reference made to the SEPP (Waters) should be changed to the ERS.	Agreed and completed	TBC	Final	ok	No further action			Y
42	10.4		Draft	It is acknowledged that impacts to a known *current* third party groundwater user are unlikely based on the modelling; however, it should be recognised that unregistered bores or newly installed bores could be established at any time. It would be useful to note how close these could potentially be to the source area (i.e. could they be substantially closer than the 400 m stated here based on known registered users?).	Modelling has shown there is no risk to water quality and groundwater, it is a sink. In addition there is no likelihood that unregistered bores or new bores could be installed within 400m of the CLA area in any direction due to the extent of Alcoa mine and land management area.	The constraints on any future groundwater well installations should be clearly noted.	Final	ok	No further action			Y
43	10.4	Risk Assessment Summary	Draft	In relation to the risk assessment summary, it is considered that if contamination occurred disruption would be more likely in the order of a year (i.e. major consequence). Risk is unchanged given event is appropriately classified as rare.	Can you please clarify further the thoughts or basis for the major consequence?	As discussed, this was related to the likely remediation timeframe being > 1 year	Final	This has been changed in the risk assessment table, however, the text in the last paragraph on pg 127 needs updating also.	Table 10-5 (Element 2.3) and the Risk Assessment Summary section (first bullet point) now agree, in terms of the major consequence associated with potential groundwater remediation taking greater than 1 year.	Final	ok	Y
44	10.4		Draft	We think the conclusions are reasonable based on the evidence presented, insofar as they relate specifically to the likely impacts of the submergence of the encapsulated leached ash in the future pit lake, which is the subject of this review. However, in reviewing the risk assessment it is clear that the broader risks to lake water quality (above and beyond the LA), and how that may impact on the environment and communities could be far more substantial. It assumed that these risks have been/are being assessed separately.	This will be presented in the MRCP, however, we appreciate acknowledgement of objectives of this work. We will add some text to clarify this further for the reader as this may also to be a question raised by others also re the relationship of the subject of this review to the future MRCP.	ok	Final	ok	No further action			Y
45	10.4		Draft	Table 10-5: It is stated that 'Historical water body water quality precludes beneficial uses which is consistent with background surface waters including Anglesea River and Salt Creek.'. Suggest this be re-worded to 'Historical water body quality is consistent with background surface waters including Anglesea River and Salt Creek and therefore environmental value of water dependent ecosystems and species with regard to the local catchment is protected'. This change is recommended as stating that the environmental value (beneficial use) is precluded implies non-compliance with the ERS, however, that does not appear to be the case.	Adjust as suggested Completed	TBC	Final	On further review, including the supplementary report (EHS, 2021c), it is not clear that the claim that "environmental values of water dependant ecosystems and species is protected" can be substantiated with respect to boron. The proposed WQPT for boron (and by extension the lake water quality) is above the guideline level contemplated in the supplementaty report (EHS, 2021c) and there is no documentation of subsequent site specific risk assessment for grazing mammals or other ecological receptors. We suggest that this staement be qualified, with boron noted as an exception that requires further site specific risk assessment.	Additional wording has been added to Section 4.2.1: *However, it is accepted that the boron concentrations considered within EHS Support (2021c) are lower than the interim WQPTs values, particularly for the DBF and BF groundwater and that this groundwater quality data is associated with the power station monitoring network and not in the vicinity of the CLA area. Therefore, further future site-specific risk assessment is proposed to assess the potential risks to ecological receptors from boron sources (in addition to the CLA area). Additional risk assessment will be conducted as part of the MCRP finalisation. .*	Final	ok	Y
46	10.4		Draft	Table 10-5: see previous comments on the performance objectives and the appropriateness of using historical water body water quality as a benchmark.	Refer back to Item 17 response	Resolved during discussion. It is understood that catchment background will be adopted.	Final	See Item 17 response	Updated equis report for the water body. 2021 to 2022 used for table as the more recent data has associated QAQC.	Final	ok	Y
47	10.4		Draft	Table 10-5: There are numerous references to the "licensed mine boundary" as a point of compliance. Will this boundary be defined and recognised in perpetuity, or should a different long term boundary/benchmark be defined?	The licensed mine boundary will remain in effect until Alcoa is in a position to surrender this to the state, which in turn can only be done once the state accepts that Alcoa has met all of its obligations and reduced long term risk to an acceptable level. In effect then, the licensed area will remain in place for as long as it needs to mitigate any risks.	ok	Final	ok	No further action			Y
48	10.4		Draft	Table 10-5: The erosion and sedimentation hazard could conceivably exist post submergence of the ash, particularly when water column heights in the area are relatively low. This could occur through wind and wave driven turbulence and other factors. What monitoring could be implemented to assess this longer term? It may be appropriate, for example, to conduct periodic bathymetry surveys to monitor the cap integrity.	The steady state 12 m water column height is considerable, refer back to risk assessment contingency measures. Re surface water or wave erosion this is low risk due to the very shallow slope of the CLA area as noted in the risk assessment, and is supported by observations onsite. Re bathymetric please refer to Item 5 comments - for further discussion with Bluesphere.	This is outside our area of expertise, but we expect the erosion from wave action could also occur during filling (i.e. when water column heights above the CLA are lower i.e. 0.5, 1, 3 m etc). Risk may be addressable through monitoring (e.g. bathymetric survey).	Final	ok, as discussed, it is understood that the specifics of a post submergence monitoring plan are being developed, however, at a high level it is agreed that most submergence monitoring (e.g. via bathymetric survey) will be undertaken until such time that it is evident that the CLA is stable. Text in Section 10.5 should be updated to reflect this.	Noted, following wording added to Table 10-5, element 3.3: *Post submergence, bathymetric surveillance will be conducted to monitor the elevation and stability of the CLA area.* A post submergence plan will be completed before inundation is complete	Final	ok	Y
49	10.4		Draft	Table 10-5: Regarding erosion and sediment control, whilst beyond the scope of our review, has rock armouring been considered or is it warranted? The integrity of the capping is obviously critical to a number of the assumptions within the modelling and subsequent risk assessment. It is expected that this will be a major consideration for EPA given the fundamentality of capping as a risk minimisation measure.	Monitoring of the cap cover integrity will occur during inundation when erosion is most likely due to surface water or wave erosion, and also refer to Item 48 comments whereby armouring would then not be considered necessary due to the low risk.	Agree that cap degradation is most likely during inundation, but it is still possible post inundation.	Final	ok, See response to Item 48	Noted, following wording added to Table 10-5, element 3.3: *Post submergence, bathymetric surveillance will be conducted to monitor the elevation and stability of the CLA area.* A post submergence plan will be completed before inundation is complete	Final	ok	Y
50	10.4		Draft	Table 10-5: Reference should be made to the dispersity testing as that informs a scenario where ash is mobilised into the water column through erosion and creates an aesthetic issue (i.e. cloud of silty water affecting the amenity of the water body)	Data supports that dispersion is unlikely but it can also be mentioned in this section Completed	TBC	Final	ok	No further action			Y
51	10.4		Draft	Groundwater monitoring is included in the monitoring and reporting program. Note we have not reviewed the locations of and appropriateness of monitoring locations and testing regimes. Monitoring frequencies seem reasonable.	Noted	TBC	Final	ok	No further action			Y
52	11		Draft	We note the usefulness of the literature review in establishing best available technologies and reiterate that this proposal has much in common with disposal of materials at sea, including dredge material disposal grounds.	Noted	TBC	Final	ok	No further action			Y
53	11		Draft	Perhaps note in the modelling summary that under sensitivity analysis particles did move further the 49 m, but still not distances that indicated impacts to receptors	Check and sentence added to Sec 11 summary	TBC	Final	ok	No further action			Y
54	11		Draft	Replace "BlueSphere consulting" with "BlueSphere Environmental"	Agreed and completed	TBC	Final	One reference to BlueSphere Consulting on p.137, should be BlueSphere Environmental	Corrected	Final	ok	Y
55	11		Draft	Suggest remove reference to verifying the location of the CLA as it is understood the focus was to characterise the physical and chemical nature of the CLA.	The location of the CLA did not have a detailed survey and so the field sampling in 2021 and 2022 did contribute to the verification of the CLA area.Concluding paragraph is kept the same and second paragraph after the bullets at the begining of Section 11 has removed the objective of verification.	TBC	Final	ok	No further action			Y
56	1.2	Table 1-1					Final	Item 5 - Please cite the literature review here also as a relevant response item	Noted and following text added to Table 1-1, item 5: *Literature review of national and international examples of (leached) ash management*	Final	ok	Y
57	4.1	Tables 4-1 and 4-1					Final	Where an EV is not relevant, provide substantiation, e.g. no existing registered users, contraints on future use etc Also, should the EV of Water Dependent Ecosystems and Species in relation to groundwater be relevant given in time the waterbody and the groundwater are expected to be in hydraulic connection.	Justification of the relevancy of an environmental value has been provided in Section 4.1 (final paragraphs). Additional summary paragraph has been added. Additional commentary has been added to Table 4-1 (EV - WDES) to state that currently hydraulic connectivity between the water body and the DBF/BF does not exist however this will change in the future: *No – currently the DBF/BF lithological unit surrounding the water body is dry. However, it is acknowledged that the DBF/BF will become saturated in the future, hydraulic connectivity between the water body and the DBF/BF will be established and this environmental value will be realised .*	Final	ok	Y
58	4.2.1						Final	Paragraph 3 - last sentence appears to be a novel approach to quantifying exceedences; we are not sure this approach is consistent with the species sensitivity distribution models used to derive the generic criteria. This approach should either be further substantiated or omitted as it is not critical to the discussion.	This sentence has been removed as suggested.	Final	ok	Y
59	4.2.1						Final	The fourth paragraph refers to risk assessments undertaken in relation to boron. Further discussion should be provided with respect to Boron and exposure models such as grazing mammals ingesting pit lake water. Also refer to Item 45.	Refer to item 45 response	Final	ok	Y
60	4.7						Final	Paragraph 4 states that "the application of interim WQPTs will ensure no deterioration of environmental values and receptors as the water body filling strategy proceeds". Its not clear that this can be substantiated. Perhaps they will help to identify if deterioration, or further deterioration, occurs. This also somewhat contradicts our understanding that the finalisation of the filling strategy will prompt development of the the final WQPTs under the MCRP. Similarly, the statement "The risk to environmental values of water dependent ecosystems and species will be low and manageable using contingency measures.." requires substantiation, particularly with respect to boron and exposure models such as grazing mammals ingesting pit lake water.	Additional wording added to paragraph: The application of interim WQPTs *and the final WQPTs will aid in the identification of any* deterioration of environmental values and receptors as the water body filling strategy proceeds and the CLA area is inundated. As described in the sections above, the environmental values of the surrounding natural catchment must be protected. The risk to environmental values of water dependent ecosystems and species will be low and manageable using contingency measures which will be developed as part of the water body filling strategy. *It is acknowledged that boron concentrations in the water body and (potentially) the DBF and BF are elevated and further site specific risk assessment is proposed to assess the potential risks to ecological receptors from boron sources (in addition to the CLA area). Additional risk assessment will be conducted as part of the MCRP finalisation.*	Final	ok	Y
61	4.8						Final	Suggest adding the words 'apart from aesthetic enjoyment' after the words 'recreational uses'.	Completed	Final	ok	Y
62	7.1						Final	The geometric means should be stated. Also please check discussion in this section and elsewhere (e.g. Section 10.1) which refers to permeabilities all being less than 1 x 10-9 m/s - some values are above this. It is noted that it appears that the correct permeabilities have been used in the modelling.	Geometric means have been added to Table 7-1, Table 7-2 and Table 7-3. Text has been corrected to state: *geomean for each material group is less 2x10-9 m/sec with the exception of the 2021 fill material group. This result is skewed by a sample of organic clay with a permeability of 6x10-8 m/sec which is not representative of the other fill material sample permeabilities. This sample is considered to be an outlier in the dataset, however, has been retained.*	Final	ok	Y
63	10.5						FInal	It is understood that the specifics of a post submergence monitoring plan are being developed, however, at a high level it is agreed that most submergence monitoring (e.g. via bathymetric survey) will be undertaken until such time that it is evident that the CLA is stable. Text in Section 10.5 should be updated to reflect this.	Noted and following text has been added to Section 10.5: *Development of a post submergence plan which will include bathymetric surveillance to monitor the elevation and stability of the CLA area* A post submergence plan will be completed before inundation is complete	Final	ok	Y
64	11						Final	Reference to BATT should be made in the conclusions as this was the purpose of the literature review	This has been added to the fourth bullet point	Final	ok	Y

Mr Warren Sharp
Anglesea Site Manager
Alcoa of Australia Limited
Camp Road
ANGLESEA VIC 3230

Dear Mr Sharp

RE: ALCOA ANGLESEA – ASH COVERING MANAGEMENT COMMENCEMENT

I refer to Alcoa's letter of 20 November and email of 28 November 2017 in relation to the notification of intention to conduct earthworks to consolidate and cover ash under the current endorsed Mine Work Plan at the former Anglesea coal mine.

Based on the information provided in the covering letter and the *Earthworks Plan Depicting the Design to be Employed to Cover the Ash* (the Earthworks Plan), Earth Resources Regulation (ERR) has a number of questions as to how the works may impact the final rehabilitation and closure of the site.

The questions draw on comments provided to Alcoa following ERR's review of the Alcoa Anglesea Rehabilitation and Closure Plan and whether, in the absence of a response, the works can be considered 'no regrets'. Prior to Alcoa proceeding, ERR is seeking clarification on the following aspects of your intended works and their implication on the overall rehabilitation and closure of the site.

Hydrogeology/Hydrology/Geochemical

In relation to the environmental impact of the in-pit ash disposal, please address the following:

1. The Earthworks Plan makes reference to hydrogeological evaluation and geochemical simulations, however these documents have not been provided (or referenced). Are these the same models that were reviewed as part of the recent review of the Alcoa Anglesea Rehabilitation and Closure Plan 2017? If so, please consider the comments provided in the response in the context of this matter.
2. Alcoa has provided a qualitative description of the Erodible Mine Material (EMM) as having a 'low permeability', however there is no material testing data to support this statement. Similarly, permeability data for the basal clay unit would provide necessary evidence of how this unit will control fluxes.
3. The Earthworks Plan indicates that transport modelling of both the pit water body and the Upper East View Formation (UEVF) groundwater though the ash material in the pit has been simulated. As above, the supporting document has not been provided (or reference).

4. In the recent review of the Alcoa Anglesea Rehabilitation and Closure Plan 2017, the Environment Protection Authority (EPA) identified that further testing was required to characterise the ash (including leachate analysis). This raises concerns regarding the suitability of any modelling in the absence of suitable characterisation of the material.
5. The Earthworks Plan states that 'permeability testing of the compacted ash and cover materials will be used to verify the transport modelling input parameters'. Please provide the permeability values used in the modelling and the testing regime (and method) proposed to validate the model parameters. What happens if compaction is unable to achieve the modelled permeability parameters?

Geotechnical

In the broader context of pit stability, the covering of the ash was not seen as posing a significant risk. However, in order to adequately assess the risk it would have been useful if the earthworks plan was developed in accordance with typical industry practice (e.g. as per the framework outlined in AS 3798 *Guidelines on earthworks for commercial and residential developments*). A map and any modelling information (3D imagery) would also have been useful in understanding where the ash was to be placed in the pit void.

In relation to the consolidation aspects and (potential) implications to long term stability please address the following:

1. Alcoa has provided a qualitative description of the ash but no characterisation of the materials' mechanical properties. This would typically be required in an earthworks plan (as pointed out in ERR's assessment of the Alcoa Anglesea Rehabilitation and Closure Plan).
2. Alcoa states that the ash is expected to consolidate to various levels. How this was assessed in the absence of material properties (as mentioned in point 1)? The consolidation behaviour of any material is typically governed by a parameter referred to as the coefficient of vertical consolidation (Cv).
3. There are references to machinery compacting the ash and EMM to aid in the earthworks process, however owing to the limitations stated above in points 1 and 2, the implications of this has not been quantitatively assessed, and remains an untested assumption.
4. Owing to the points mentioned above, it is unclear how the ash covering works can be considered 'no regrets', i.e. if subsequent trials and testing yield lower parameters than 33 degrees (the friction angle looking to be achieved in the Alcoa Anglesea Rehabilitation and Closure Plan) what are the implications?

If you any questions of wish to discuss our comments further, please contact Andrew Radojkovic on 03 8392 6043 or andrew.radojkovic@eodcev.vic.gov.au

Yours sincerely

A Robinson

Mr Warren Sharp
Anglesea Site Manager
Alcoa of Australia Limited
Camp Road
ANGLESEA VIC 3230

Dear Mr Sharp

RE: ALCOA ANGLESEA – ASH COVERING MANAGEMENT COMMENCEMENT

I refer to Alcoa's letter of 20 November and meeting of 30 November 2017 in relation to the notification of intention to conduct earthworks to consolidate and cover ash under the current endorsed Mine Work Plan at the former Anglesea coal mine. Earth Resources Regulation (ERR) has considered your proposal and notes the following:

- Alcoa is proposing to cover the ash as a dust mitigation measure. This will reduce the likelihood of ash dust leaving the site and impacting on the Anglesea township.
- The ash has already been consolidated and will be covered by 1 m of silt and clay overburden which will be compacted by the earthmoving equipment.
- The ash will be relocated to the consolidation area (at the eastern end of the pit void) and will ultimately consist of a 4 m thick horizon between RL -15 and -8 m extending over an area of approximately 7 ha.
- Mine water recovery modelling forecasts that without the re-diversion of Salt Creek that the water level in the pit will not recover to RL -15 m until approximately April 2024.

Based on the information provided in the covering letter, the *Earthworks Plan Depicting the Design to be Employed to Cover the Ash* and subsequent e-mail and attachments of 28 November 2017, ERR is satisfied that the works as described take place between December 2017 and March 2018.

ERR notes that the questions raised in the correspondence of 29 November 2017 relating to the potential impacts of the ash on water chemistry, hydrology, hydrogeology and stability will be considered in Alcoa's revised rehabilitation and closure plan.

If you any questions of wish to discuss our comments further, please contact Andrew Radojkovic on (03) 8392 6043 or andrew.radojkovic@eodcev.vic.gov.au

Yours sincerely

VICTORIA State Government

20 October 2021

Mr Warren Sharp
Alcoa of Australia Limited
205 Coalmine Road
Anglesea VIC 3230

Dear Mr Sharp,

Approval pathway under the Environment Protection Act 2017

Thank you for your correspondence in relation to an EPA approvals pathway for assessing the detailed design for the ash landfill cap dated 17 September 2021.

Based on the information provided and discussions at the co-regulators forum, EPA understands that the proposal has changed since 2017 and that Alcoa of Australia Limited ("Alcoa") is now pursuing the option of using water from Upper East View Formation to fill the pit with water. An application sent to EPA would need to reflect on this change, including the change in risk. EPA also understands that the ash landfill is intended to be submerged under water, once an approved cap is in place.

EPA's response to the matters raised are noted below. Please note that this information is of a general nature. EPA will determine any future application based on the evidence and information provided at the time of the application.

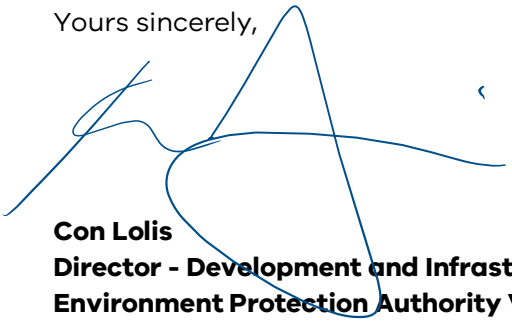
Assessment of landfill cap

To surrender the ash landfill from EPA Operating Licence OL000011429, Alcoa would need to submit an application under the *Environment Protection Act 2017*. EPA's position, based on the available information, is that Alcoa should seek an approval for the landfill cap through the licence surrender process. In that process, the following information should be provided:

- detailed design of the landfill cap
- a description of the targeted performance (short and long-term) and outcomes of the proposed landfill cap
- information that supports how the proposed cap is able to achieve the targeted performance and outcomes
- monitoring results capable of confirming that the cap is performing in line with targeted performance and outcomes, short and long term
- detailed and verifiable confirmation that the proposal constitutes best available techniques
- independent technical peer-review of a qualified expert (or experts) that have expertise suitable to undertaking a technical peer-review of the proposal
- measures taken to comply with the General Environmental Duty, relevant Environment Reference Standards and principles of the *Environment Protection Act 2017*.

If you need additional information or assistance, please contact Andreas Elvin at Andreas.Elvin@epa.vic.gov.au or on (03) 9695 2942.

Yours sincerely,



Con Lolis

Definitions

Term	Definition
Closure	A life-of-operation process which ultimately can culminate in relinquishment. It broadly includes planning, decommissioning, rehabilitation, monitoring and maintenance.
Community	A broad term used to define groups of people, whether they are stakeholders, interest groups or citizen groups. The community may surround a geographic location (community of place), be a community of similar interest (community of practice) or have a special interest or legal interest in the land (community of standing). Community may also refer to a community of flora and fauna i.e. an assemblage of organisms existing together in the wild.
DJPR	Department of Jobs, Precincts and Regions
Disturbed footprint	The area or extent of un-rehabilitated land within the mining licence that has been altered by operations and which has not yet been rehabilitated. The disturbed footprint will vary with time. The current disturbed footprint is that which currently exists. The end of mine life disturbed footprint is the estimated area of disturbance that will exist at the cessation of operations.
End of mine life	The date at which production is proposed to cease under the currently approved work plan.
ERR	Earth Resources Regulation, the principal regulator of mines and quarries in Victoria
Infrastructure Mining Licence*	A mining licence solely for the construction of a facility or other infrastructure to be used for the purpose of mining under another mining licence
Legacy site	A facility or former disturbed footprint within the mining licence which is no longer part of the active operations
Mine*	Any land on which mining is taking place under a licence
Mineral*	Any substance which occurs naturally as part of the earth's crust: a. Including: i. oil shale and coal; and ii. hydrocarbons and mineral oils contained in oil shale or coal or extracted from oil shale or coal by chemical or industrial processes; iii. bentonite; fine clay; kaolin; lignite; minerals in alluvial form including those of titanium, zirconium, rare earth elements and platinoid group elements. iv. quartz crystals; zeolite. b. Excluding water, stone, peat or petroleum.
Mining hazard#	Any mining activity and circumstance that may pose a risk to the environment, to any member of the public or to land, property or infrastructure in the vicinity of work carried out at a mine.
Minister	Victorian Minister for Resources
MRSDA	*Mineral Resources (Sustainable Development) Act 1990*
Plant*	Means buildings, structures, works or other machinery (whether fixed or mobile) and all other installations or equipment used in the doing of work under a licence or an extractive industry work authority.

Term	Definition
Reasonably practicable	'As far as reasonably practicable' under section 40(3)(c) of the MRSDA and Regulation 45 of the Regulations is based on the approach to precaution-based risk analysis under the *Occupational Health and Safety Act 2004*. Under section 20(2) of the Occupational Health and Safety Act 2004, reasonably practicable means: that which is, or was at a particular time, reasonably able to be done to ensure health and safety, taking into account and weighing up all relevant matters including: a. the likelihood of the hazard or the risk concerned eventuating b. the degree of harm that would result if the hazard or risk eventuated c. what the person concerned knows, or ought reasonably to know, about the hazard or risk, and any ways of eliminating or reducing the hazard or risk d. the availability and suitability of ways to eliminate or reduce the hazard or risk e. the cost of eliminating or reducing the hazard or risk.
Regulations	Mineral Resources (Sustainable Development) (Mineral Industries) Regulations 2019
Rehabilitation	The return of disturbed land to a safe, stable and non-polluting condition to an agreed end use. It broadly involves landform design, construction and shaping; materials characterisation, handling and placement; surface water management and revegetation. It comprises two phases: • Rehabilitation execution – comprising design and permitting plus most of the physical works on sites, such as decommissioning, decontamination and demolition of infrastructure; bulk earthworks; capital works; and topsoiling/revegetation. • Post rehabilitation execution – monitoring, maintenance and land management following the rehabilitation execution phase that extends until rehabilitation objectives have been achieved.
Risk management plan	Regulations 40 and 45 of the Regulations states that a risk management plan is required in a work plan for a mine. The risk management plan includes of a risk treatment plan for each mining hazard that is identified and a risk register.
Risk register	A risk register is a summary table of the risks identified for the mining hazards and includes the inherent and residual risk ratings. It is a component of the risk management plan.
Risk treatment plan	A risk treatment plan addresses the risks associated with one of the mining hazards identified. It specifies: a. The control measures to eliminate or minimise, as far as reasonably practicable, the identified risks associated with the particular mining hazard; b. The objectives, standards or acceptance criteria for those control measures; c. The monitoring program that will measure performance against all the specified objectives, standards and acceptance criteria; and d. The arrangements for reporting on performance against all the specified objectives, standards and acceptance criteria. Risk treatment plans for each of the identified mining hazards and a risk register form the risk management plan.
RRAM	Resource Rights Allocation and Management business portal is the ERR online software application used for the management of licences and work plans. Registered subscribers can use RRAM to apply for a licence, submit a work plan or report, track an application status and pay fees.

Term	Definition
Secondary Consent	Secondary consent allows for an expeditious means of dealing with changes to Planning Permits, but the extent of changes which can be sought are limited and third parties are prevented in becoming involved in the process. Councils generally only allow a permit holder to use this option for minor changes to the Planning Permit. Secondary consent is made available under the wording of a permit which has already been granted and is permissible under permit conditions.
Sensitive receptor	Sensitive receptors are people or other organisms that may have an increased sensitivity or exposure to an emission by virtue of their age and health (e.g. schools, day care centres, hospitals, nursing homes), status (e.g. sensitive or endangered species), proximity to the contamination, dwelling construction, or the facilities they use (e.g. water supply). For the purposes of a work plan the sensitive receptors are described in relation to the environment, any member of the public, or land, property or infrastructure in the vicinity of the proposed work.
Work plan	The work plan is the primary document describing the permitted activities to be undertaken on a mining licence It is intended to provide guidance to operations staff at the mine as well as informing other readers such as council or government officers in order to facilitate decisions, approvals, compliance, and enforcement functions. It must be clear, concise and contain sufficient detail to enable a reader to understand the activities proposed to be undertaken at the site, their potential risks and impacts, and the control or management actions required. For further information relating to a work plan refer to section 40 of the MRSDA.
Work plan variation	If the original scope of work changes after the plan has been approved by ERR, then the work plan needs to be **varied** to include these changes; this is known as a work plan variation.
Work	Any activity that is connected to or is incidental to the mine activities permitted under the approved Mining Licence and work plan.

Note:
** definition in MRSDA*
 # definition in Regulations

1. Background

1.1 What is mining industry?

Mining is the extraction of minerals from land for the purpose of producing them commercially. This includes processing and treating ore.

1.2 What do I need to develop a mining industry project?

Before land can be developed for mining industry, in most cases you will require:

- a **mining licence**;
- an **approved work plan** or compliance with the Code of Practice provision under Part 8A – Section 89A of the *Mineral Resources (Sustainable Development) Act 1990* **(MRSDA)**;
- a **rehabilitation bond**;
- a **planning permit** under the Planning and Environment Act 1987;
- any other licence(s) and/or approval(s) required for the project under other planning and environment legislation;
- the consents of, and **compensation agreements** with, owners and occupiers of the land affected by the project;
- compliance with all the requirements of **section 42** (commencement of work under mining licence or prospecting licence) of the MRSDA; and
- provision of seven days' notice in writing to the Chief Inspector of Mines (ERR Director Regulatory Compliance) and the owners and occupiers of the land affected of the **intention to commence work**.

Exceptions to these requirements are explained in Section 2 of this guideline.

Approval processes under the MRSDA are administered by Earth Resources Regulation (**ERR**) within the Department of Jobs, Precincts and Regions (**DJPR**). Further information about ERR, mining licences, work plans and other related matters is available on the ERR website at http://earthresources.vic.gov.au/earth-resources-regulation.

1.3 Purpose of this guideline

The purpose of this guideline is to provide guidance on the preparation of work plans, work plan variations, and work plan notifications for mining industry projects, to meet Victorian regulatory requirements.

1.4 Scope of this guideline

The scope of this guideline includes:

- when a work plan or work plan variation is required (Section 2);
- when, and with what information, it is recommended to engage with ERR (Section 3);
- the content that needs to be in a work plan (Section 4);
- the content that needs to be in a work plan variation (section 5);
- the steps to seeking assessment of a work plan or work plan variation (Section 6); and
- the notification (administrative update to a work plan) threshold and process (Section 7).

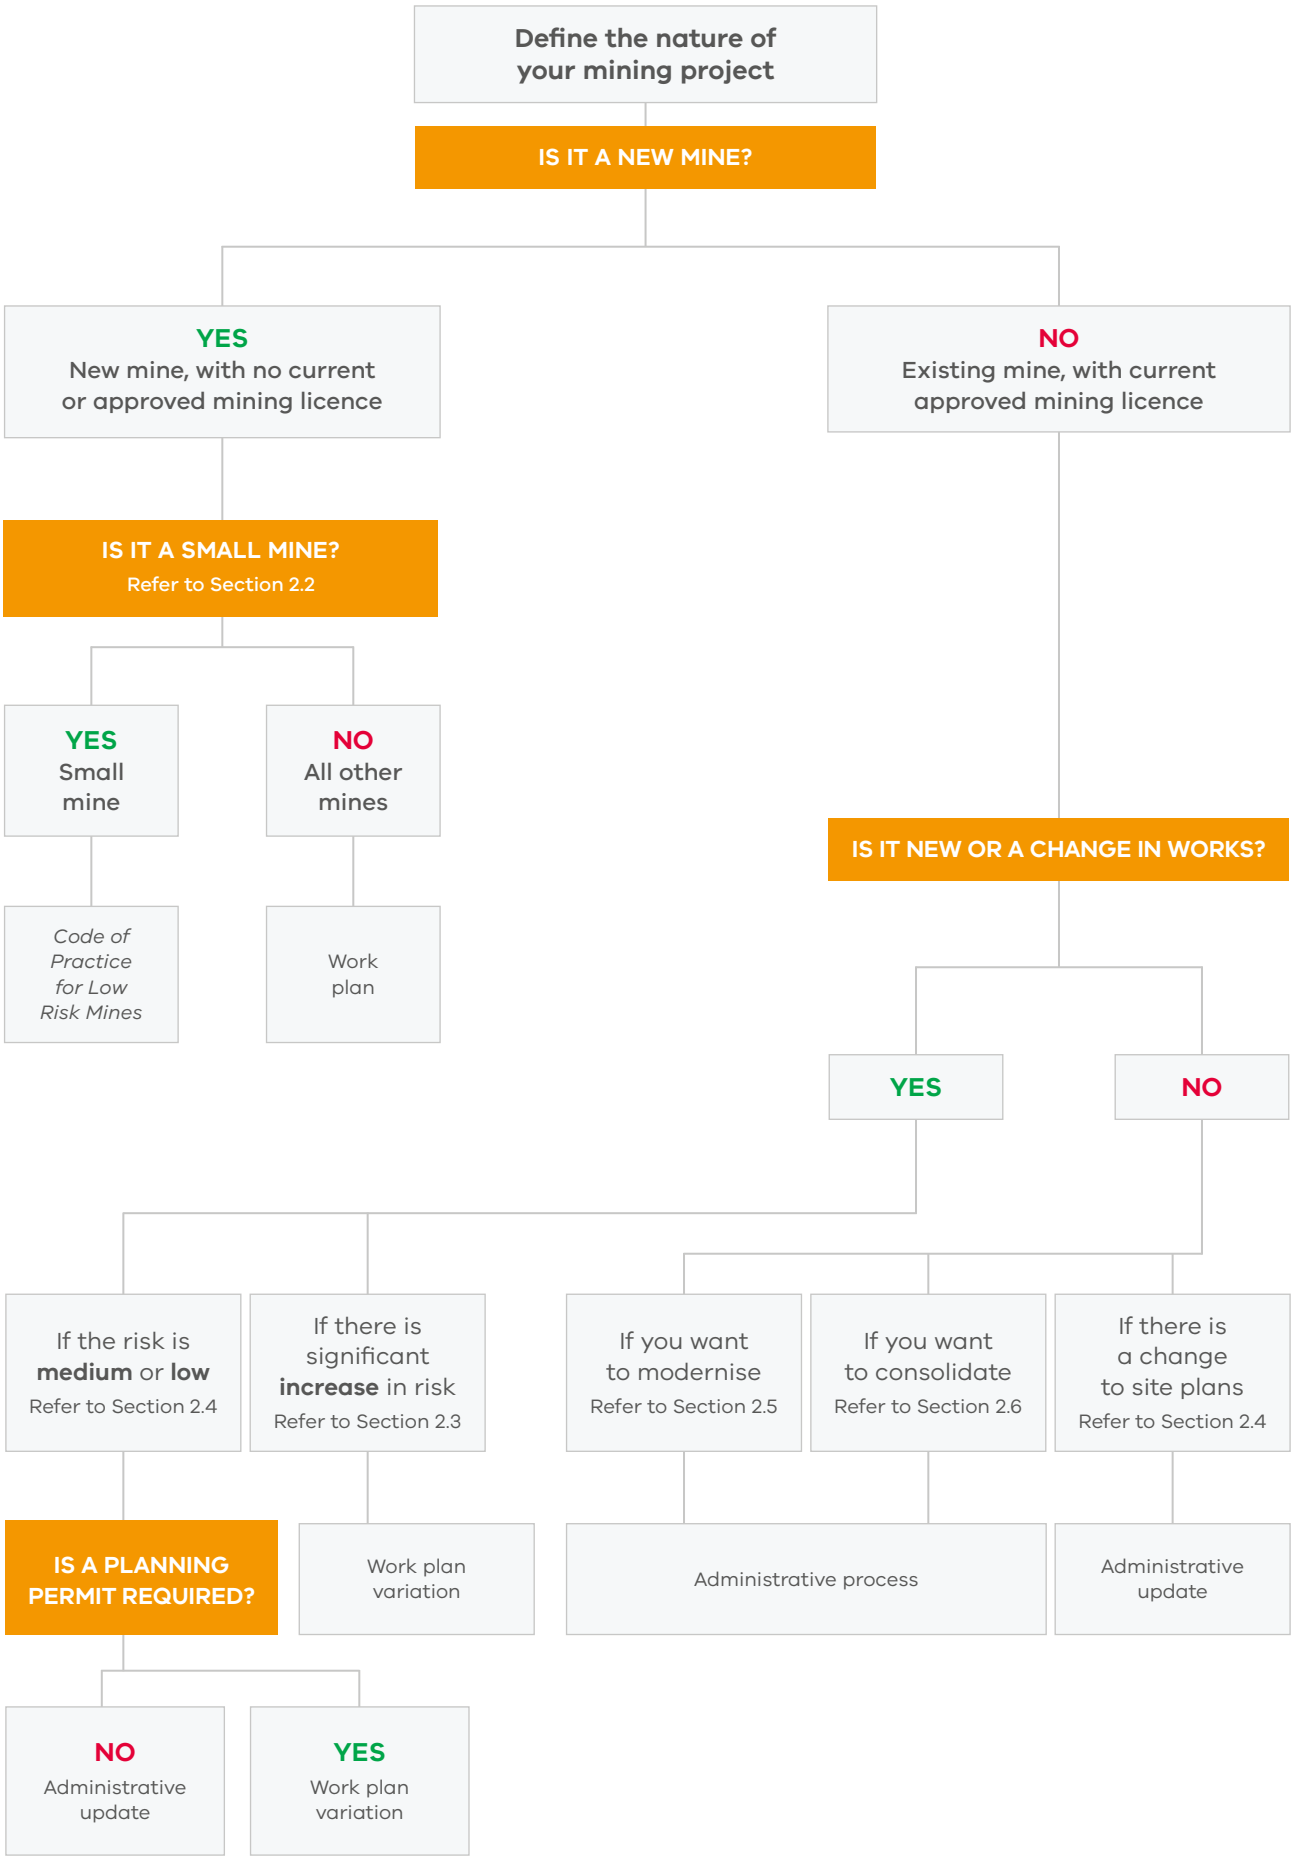
Figure 1 provides a flow chart that you can use to determine what type of application is appropriate in your case, and where to find the relevant information in this guideline.

The scope of this guideline does **not** include:

- requirements for declared mines or coal mines;
- requirements for infrastructure mining licence work plans;
- preparation of extractive industry or exploration work plans;
- assessment of proposed changes to the boundary of an approved mining licence;
- preparation and assessment of rehabilitation bonds.

If you are looking for assistance in these matters, please contact the ERR Licensing Team. Up-to-date contact details can be found at http://earthresources.vic.gov.au/earth-resources/contact-us.

Figure 1: Flow chart to determine your application type and the relevant section of this guideline



2. When is a work plan or work plan variation required?

2.1 What is a work plan?

A work plan is a document that needs to:

- describe the nature and scale of the proposed mining activities
- identify and assess all risks the works may pose to the environment, to the public, or to nearby land, property or infrastructure (known as '**mining hazard**')
- include a risk management plan that specifies the measures the licence holder will use to eliminate or minimise identified risks and monitor performance
- include a community engagement plan
- include a rehabilitation plan.

Section 4 of this guideline provides further detail on the content of a work plan.

2.2 When is a work plan required?

A work plan must be submitted to ERR and approved before any mining activity commences.

However, this requirement does not apply to mining projects that:

- covers an area of 5 hectares or less; **and**
- does not require underground operations, blasting, the clearing of native vegetation or the use of chemical treatments.

If a work plan is **not** required, compliance with the *Code of Practice for Low Risk Mines* (**the Code**) will be required as a condition of the mining licence.

http://earthresources.vic.gov.au/earth-resources-regulation/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/code-of-practice-for-low-risk-mines

If ERR is satisfied that the work proposed does not trigger the need for a work plan, ERR will acknowledge in writing that only compliance with the Code is required.

2.3 What is a work plan variation?

A work plan variation is a document that seeks approval for changes in work that are not consistent with an existing approved work plan.

Section 5 of this guideline provides further detail on the content of a work plan variation.

2.4 When is a work plan variation required?

A work plan variation is required when there is a change in work, or new work is proposed that has not been approved under an existing work plan.

'**Work**' is any activity that is connected to or is incidental to the mining activities permitted under the approved work plan.

A '**change in work**' is work that is not consistent with an existing work plan.

'**New work**' is work that is not approved under the existing work plan, or mining licence.

Changes in work that trigger a work plan variation are those that involve:

- a significant increase in risk;
- a change to the community engagement plan as a result of new work or a change in work; or
- a change to the rehabilitation plan as a result of new work or a change in work.

A '**significant increase in risk**' is where the residual risk (assessed under ERR's risk matrix in Appendix A of this guideline) is categorised as greater than **medium** after factoring in the adequacy of existing controls and the proposed application of additional controls (where these additional controls are listed in guidance material published by ERR, such as those in Appendix C of this guideline).

Section 5.3 of this guideline presents ERR's risk framework and explains how to assess residual risk.

If you are an existing licence holder, you may need to prepare a work plan variation for statutory endorsement as part of a planning permit amendment application. In such cases you should seek advice on planning permit requirements from the relevant planning authority.

2.5 What changes do not require a work plan variation?

If you have an approved work plan, you may consider making a **notification** to ERR for changes to work or new work which do not trigger a work plan variation. Instances that do not trigger a work plan variation include:

- No new risks, and existing risks are categorised (after being assessed under ERR's risk matrix in Appendix A) as **low or medium**;
- Changes to maps or drawings associated with a licence and/or work plan.

Examples of work that may not trigger a work plan variation and are therefore suitable for notification are provided in Appendix D. Section 7 of this guideline outlines the process and information required by ERR to accept a notification.

2.6 How can I modernise my work plan?

There is no requirement to transition a work plan approved prior to 8 December 2015 to a modern one that meets the current requirements of the MRSDA and its Regulations. However, modernising your work plan would simplify any future applications for variation and streamline the consultation process with referral authorities. In most cases, modernising your work plan is purely an **administrative process** (i.e. will not trigger a work plan variation) and will not have implications for existing planning approvals or referrals.

A modern work plan is:

- short, clear and written in plain English;
- fit for purpose, meeting the current requirements of the MRSDA, its Regulations and the needs of the business;
- understandable by all users, including co-regulators;
- detailed enough to describe operations and risks;
- focussed on how risks will be managed; and
- reflects current and planned operational circumstances.

A modern work plan includes:

- an overall description of the site and planned site operation – this is clearly written to accurately describe the key features of the operation, and enable minor on-ground changes that are consistent with the description without further approval;
- a risk management plan – this describes the identified mining hazards, your planned control measures and your monitoring and reporting program;
- a community engagement plan; and
- a site rehabilitation plan.

Modernising a work plan involves adding the key parts which would now be required in a new work plan, which are a mining hazard assessment and a risk management plan.

Modernising a work plan can also involve removing information that is no longer required, such as a lengthy detailed description of proposed work.

A modernised work plan can be approved by ERR without further consultation with a council or referral agencies, because there are no changes that would trigger a work plan variation.

A modern work plan will incur no fee, where no variation is required.

Please contact the ERR Assessment Team prior to preparing your modernised work plan. Up-to-date contact details can be found at http://earthresources.vic.gov.au/earth-resources/contact-us.

2.7 How can I consolidate my work plan and variations?

Many licence holders have work plans with variations that have not been consolidated into a single work plan.

ERR has an **administrative process** to simplify work plans by consolidating relevant work plan content and all variations into a single document. Consolidation involves taking a work plan which was approved before 8 December 2015 and identifying the current components that define the scope of the mining licence.

This consolidation process will involve consultation with licence holders as required.

Consolidation will:

- not change any regulatory requirements on operators or cause existing rights to be amended or revoked;
- not involve a statutory approval process or consultation with the relevant municipal council or referral authorities; and
- incur no fee, where no variation is required.

Once accepted by ERR, the consolidated work plan forms a single document which incorporates all approved works that may be carried out on a site.

ERR will approach selected licence holders to consolidate work plans that contain information that is no longer required due to multiple changes over time. This will involve creating an index and bringing to the front of the work plan all the current arrangements that apply on site. Any ancillary information will then form attachments to the work plan.

It should be noted that ERR may require you to submit a work plan variation if any new or changed hazards or risks that have not been adequately addressed are identified during the consolidation process.

If you are interested in consolidating your work plan and variations, please contact the ERR Assessment Team. Up-to-date contact details can be found at http://earthresources.vic.gov.au/earth-resources/contact-us.

3. What is the recommended pre-submission process?

3.1 Background

The approval process for mining industry work plans and work plan variations depends on whether a planning permit is required.

All new work plans require a planning permit unless the proposed work has been subject to an Environment Effects Statement.

> Proposed work that has been subject to an Environment Effects Statement (EES) under the Environment Effects Act 1978 does not require a planning permit. Use this guideline in preparing an application for work plan as an outcome of an EES. You should contact ERR for advice on the approval process for work plans following an EES.

If the proposed changes to work are compliant with a current planning permit, or secondary consent under an existing planning permit is required, then only the approval steps apply.

If the proposed changes to work require a new planning permit or a planning permit amendment, the MRSDA requires the additional step of statutory endorsement of the work plan or work plan variation by the Department Head or delegate[1] before you submit the proposal to the planning authority for assessment.

3.2 Recommended pre-submission steps

> You are not required to undertake these pre-submission steps. However, these steps are recommended to avoid delays due to misunderstanding of council or referral authority requirements.

The recommended work plan (or work plan variation) pre-submission steps aim to equip you with the information needed to prepare an application that meets statutory requirements.

The recommended pre-submission steps are outlined below and in Figure 2:

1. Contact ERR
2. Submit initial proposal
3. Arrange, conduct and record site meeting
4. Engage relevant agencies
5. Arrange pre-submission briefing with ERR (optional)
6. Submit work plan.

1 e.g. Director, Statutory Authorisations, ERR and referred to as 'the regulator' for the purposes of these guidelines

Figure 2: Recommended pre-submission steps

3.2.1 Contact Earth Resources Regulation

You may contact the ERR Assessments Team via phone or email to briefly outline the nature of your proposed project. A list of ERR contacts is available at https://earthresources.vic.gov.au/about-us/contact-us.

An Assessments Officer will have a discussion with you to understand the nature of the proposed project and explain the process required.

The Assessments Officer will determine if the proposed project is exempt under the MRSDA and does not require a work plan or work plan variation.

If the project requires a work plan (or variation), then ERR will email you the relevant information, such as:

- an *Initial Proposal Information* request;
- ERR work plan expectations; and
- a community engagement plan template and guidance.

3.2.2 Submit initial proposal

You should return the completed initial proposal to ERR by email to Workplan.Approvals@ecodev.vic.gov.au prior to organising the initial site meeting (refer to Section 3.2.3).

When ERR receives the initial proposal an Assessments Officer will be nominated as your primary contact.

The **initial proposal information** to be submitted should include:

- **Description of the operation**

  For a new application: a brief description of the proposed operation and its location (including formal address).

  For work plan variations: a brief description of the existing operation, and details of the new or changing works.

  You should include the following (where relevant) as part of the description of operations:

  - Maximum depth of works (pit and/or underground)
  - For pits, include the batter and bench profile detail
  - Method of processing
  - Annual production estimate (tonnes)
  - Containment dams (water/tailings)
  - Predicted offsite discharges
  - Impact to native vegetation
  - Presence of waterways and potential waterway interception
  - Groundwater interception
  - Blasting.

The initial proposal should be a summary of the available information relevant to the proposal. Site investigations specific to the proposal are not a requirement.

- **Agreements**
  - Evidence that you have reached a commercial and/or compensation agreement with the relevant landholder(s).
- **Planning**
  - An indication of whether a planning permit is required.
  - *Planning Property Report*: current report for all the properties included in the application/tenement area. All pages of the report must be included. Planning Property Reports can be obtained, free of charge, from http://www.land.vic.gov.au.
  - *Land Title Documentation*: current register statement for the Certificates of Title, with copies of plans, for all titles to be included in the tenement area. Most register statements do not include a map, so this must be obtained. In addition, confirmation of any depth limitation on the title(s) is required. Land title documentation can be obtained, for a fee, from https://www.landata.vic.gov.au/.
- **Maps**
  - A map(s) with scale and key showing the location of:
  - The mining licence boundary
    - For a new work plan, the map must also include GDA94 coordinates (easting and northing) for each corner defining the mining licence area
    - For a work plan variation, the map must include the current and proposed extent
  - The extent of the activity footprint (i.e. the extraction area or the extent of the underground mining operations). If this area is changing as a result of a work plan variation, include the current and proposed extent
  - Nearest sensitive offsite receptors
  - The extent of the geotechnical risk zone. ERR guidance on the assessment of geotechnical risks is available at http://earthresources.vic.gov.au/earth-resources-regulation/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/guidance-material-for-the-assessment-of-geotechnical-risks-in-open-pit-mines-and-quarries.
  - Any relevant landform feature (e.g. river) and/or infrastructure (e.g. high voltage power line, road or freeway).

3.2.3 Arrange and conduct site meeting

Aims and objectives

An initial site meeting is considered the most effective way to progress your proposal. The objective of the site meeting is to discuss issues and requirements with the relevant agencies, to help you draft your work plan to successfully gain any required approvals and/or permits.

The initial site meeting aims to bring you together with all the agencies whose areas of responsibility are potentially affected by your proposal, the relevant council and the relevant ERR staff based on your initial proposal information provided. The agencies fall into two groups:

- Statutory referral authorities[2], with the exception of VicRoads in relation to traffic matters
- Other relevant non-statutory referral agencies[3] that ERR considers necessary to aid in making its decision.

The purpose of the initial site meeting is to provide an opportunity for the relevant agencies to understand the potential impacts of your proposal on their area of responsibility, and for you to understand the requirements of each agency and council so that you can address these issues during development of your work plan (or work plan variation) documentation.

Each agency will be invited to point out their requirements regarding the proposed activity (as required by relevant legislation, guidelines or policies). The meeting is often the starting point for ongoing discussions with you and further advice may be provided at a later date. After the meeting the council must advise you in writing if any planning permission is required, which in turn determines the legislative pathway followed by ERR.

The council needs to make an informed decision on the need, or otherwise, for a planning permit or planning permit amendment for your proposal. This decision needs to be made before a work plan (or work plan variation) is submitted.

If council determines that a planning permit is required for your proposal, the work plan (or work plan variation) submission will ultimately be referred to referral authorities[4]. Referral authorities may respond in one of three ways:

- They do not object; or
- They do not object if the work plan (or work plan variation) is subject to conditions; or
- They object.

2 As referred to under Part 6B of the MRSDA and required under the *Planning and Environment Act 1987*

3 As required under Section 77I(3)(d) for comment only.

4 Under the *Planning and Environment Act 1987*, as required under Part 6B of the MRSDA.

Note: The work plan (or work plan variation) may be refused if a referral agency objects.

There is no option for referral authorities to require further changes to a work plan after it is referred. Therefore, it is very important that your work plan (or work plan variation) addresses all the material concerns of the referral authorities before it is referred to them. This makes the discussions at the initial site meeting very important for the ultimate approval of the work plan.

You are strongly encouraged to undertake an initial site meeting, otherwise you may risk refusal of your work plan (or work plan variation) due to the objection of a referral authority.

Attendance at the initial site meeting

The appointed Assessments Officer will review your initial proposal and provide you with an Agency Consultation Checklist with the contact details for all referral authorities. The purpose of this checklist is to identify which parties you should invite to an initial site meeting to discuss the proposal.

It is recommended that you invite ERR, council and all identified statutory referral authorities and other agencies to the initial site meeting.

This process also applies for applications not requiring statutory endorsement, which ERR will refer to relevant agencies for consideration prior to making a decision.

In addition to providing the Agency Consultation Checklist, ERR will:

- Provide details of ERR staff that are recommended to attend the initial site meeting. Including representatives from:
  - the Assessments Team (who will be overseeing the application);
  - the Compliance Team; and
  - the Technical Services Team, depending on the issues and complexity of the proposal; and
- Suggest possible dates for the meeting to be held given ERR staff availability.

It is your responsibility to arrange a meeting with all the referral authorities and other applicable agencies identified by ERR. Ideally this meeting will be conducted on-site, however, if the site is remote the meeting may be convened at the nearest suitable town with an optional site visit prior to the meeting. Sufficient notice should be provided to enable agencies to make arrangements in advance to attend the meeting.

Preparing for the initial site meeting

It is your responsibility to organise and conduct the initial site meeting. ERR generally recommends that the meeting is arranged about four weeks in advance to ensure that the various representatives are available.

You should provide the following information to ERR, council, the referral authorities and other agencies prior to the initial site meeting:

- Details of the meeting time and place
- Land tenure/status/allotment number
- Plan of extraction or disturbed area
- Commodity/resource type
- Size/depth/predicted life of proposed activity
- Estimated total resource
- Brief description of the proposed activity (e.g. pit layout and access, blasting, dams, slimes storage facilities, hazardous waste, native vegetation etc.)
- An initial site meeting agenda – an example is provided in Appendix E1.

A list of the potential questions that may be discussed at the initial site meeting is provided in Appendix E2.

Documentation of initial site meeting outcomes

You should record key outcomes of the initial site meeting and circulate them to all invitees.

The record should include:

- a list of attendees (and those who were an apology)
- a brief summary of the project as described during meeting
- key discussion points and/or issues raised (by each agency)
- key actions.

3.2.4 Engage with relevant agencies and regulators

Early engagement with ERR, relevant referral authorities, other agencies and council is key to the efficient assessment of your proposal.

At the initial site meeting you should initiate discussions with these stakeholders to clarify their requirements and resolve any potential issues. You should notify your nominated ERR Assessments Officer if any agencies provide further advice regarding their requirements for a work plan after the meeting.

You may be required to undertake additional work (e.g. surveys, investigations, or assessments) as a result of comments provided during the meeting. You are responsible for consulting with the relevant stakeholders to ensure that your additional work meets their specific requirements.

ERR recommends that your work plan or work plan variation is submitted within 12 months of the initial site meeting. Any longer and another site meeting is likely to be required to capture current information.

While preparing your work plan, you should progress applications for any other permits, licences or approvals required prior to seeking approval or statutory endorsement under the MRSDA from ERR.

3.2.5 Pre-submission briefing to Earth Resources Regulation (optional)

For some complex work plans and work plan variations it may be beneficial to arrange a pre-submission briefing to ERR. The briefing should be no earlier than two to four weeks prior to submission, and cover details such as:

- modifications (if any) to the proposal since it was last discussed with ERR;
- engagement undertaken with referral authorities and other agencies and the outcomes of that engagement (if any);
- risk assessment and management;
- community engagement; and
- rehabilitation.

4. What needs to be in a work plan?

4.1 Work plan objectives

Submission of a work plan serves two objectives:

1. **Assessment**: It enables ERR to assess whether your work plan should be approved and, if so, any conditions that need to be applied.
2. **Compliance**: It sets out the scope of the approved works and any requirements that you must meet, including monitoring and reporting obligations. It is important that these requirements are clearly described in your work plan, as any ambiguity could result in you inadvertently breaching the MRSDA.

To achieve these objectives, all work plans must include the following key components:

Table 1: Key components of a work plan

Component	Work plans
Description of the nature and scale of the proposed mining activities	A description of all elements of the mine and its setting within the landscape.
Identification and assessment of all risks the mining project may pose to the environment, to the public, or to nearby land, property or infrastructure (known as 'mining hazards')	Identification and assessment of all risks associated with the mine during construction, operation and closure.
Risk management plan that specifies the measures the proponent will use to eliminate or minimise identified risks and monitor performance	A risk management plan for the entire mine during construction, operation and closure. This should include a risk treatment plan for every mining hazard identified.
Community engagement plan	A community engagement plan is a document that clearly identifies relevant communities and describes how, when, and what engagement will occur with those communities during all stages of an exploration project.
Rehabilitation plan	A plan for rehabilitation that covers the entire mining licence.

The information that you need to provide to ERR to meet these requirements is outlined in the following sections.

4.2 A description of the project

The aim of the project description is to define the nature and scale of the proposed mining activities in sufficient detail to:

- set the scope of the approved works
- enable assessment and management of mining hazard(s).

The project description must include:

- mine setting and location of works within the licence boundary
- location of sensitive receptors
- nature of the proposed mining works
- nature of any auxiliary works (e.g. dewatering bores; water treatment plant).

Guidance on how to describe these aspects to comply with Regulation 40 and 42 of the Regulations is provided at Appendix B.

If the required information is not included, ERR may request changes to your work plan, or refuse it. It is essential that all required information is provided to enable an efficient assessment process.

4.3 Risks from proposed works

Your work plan must identify and assess all risks the proposed mining industry project may pose to the environment, to the public, or to nearby land, property or infrastructure (known as **mining hazards**). Rehabilitation hazards must also be identified and assessed.

The identified risk(s) must be eliminated or minimised as far as reasonably practicable with risk treatment plan(s) that specify the measures you will use to eliminate or minimise those risks and monitor performance.

This section provides guidance on the identification, assessment and control of risks associated with proposed mining industry works. Further information about the risk assessment process and risk document templates are provided in Appendices A and C respectively.

Figure 3 provides a summary of the risk assessment process that you should undertake when preparing a work plan.

Figure 3: Risk assessment process for work plans

4.3.1 Identification of mining hazards

You must first identify mining hazards relevant to the proposed activities in accordance with Schedule 14 of the Regulations.

For each relevant mining hazard, a **risk event** or risk events should be identified and described based on your project description. For example, dust may be identified as a hazard relevant to the proposed activity. There may be one or many risk events associated with the hazard. A risk event associated with the dust hazard could be "unacceptable dust emissions generated at the licence boundary".

For each risk event you must also identify the consequence(s) for public safety, the environment, public infrastructure, private infrastructure and community facilities (i.e. the sensitive receptors), should that risk event occur. Sensitive receptors may be located either inside (e.g. heritage, artefact) or outside (e.g. waterways, public roads, fauna) the licence boundary and the pathway from the source of the risk event to the receptor clearly shown.

During the risk assessment process, you must identify:

- the severity of the consequence(s) – i.e. harm or damage to the environment, to any member of the public, or to land, property or infrastructure as a result of your mining activities; and
- the likelihood of the risk event occurring.

Guidance on the suggested risk assessment process is provided at Appendix A.

4.3.2 Inherent and residual risk

During the risk assessment process you will produce a **risk register** that describes and collates the identified risk events, likelihoods and consequences associated with your proposed work plan. These are called **inherent risks** and should be based on the project description.

Effective risk management requires that all risks are eliminated or reduced as far as reasonably practicable. Therefore controls should be identified and applied to each risk to achieve this. This information, including any risks eliminated, should be recorded in the risk register and risk treatment plans. For risks which are inherently **low**, and which cannot be eliminated, the explanation of why they are **low** should be captured based on the project description.

The risk assessment process should then be conducted again, assuming implementation of the identified risk controls. The new likelihoods and consequences should produce a lower risk rating, these are the **residual risks** and should be based on the project description and listed controls. Where a **residual risks** are above medium, additional controls will need to be identified to reduce the risks to an acceptable level.

Both inherent and residual risk ratings should be included in your risk register. An example risk register is provided at Appendix C1.

4.3.3 Risk management plan

Your **risk management plan** should describe and address each mining hazard relevant to your project and the controls for all identified risks (i.e. **risk treatment plans**). The plan should demonstrate that the control(s) are able to reduce the likelihood(s) and/or consequence(s) such that the residual risk is minimised as far as reasonably practicable.

The risk management plan should include:

- a summary of the project, including assumptions and sensitive receptors
- a description of the risk assessment process conducted
- a risk register
- risk treatment plan(s).
- accountable personnel for the implementation, management and review of the risk management plan.

Appendix C2 provides a template risk treatment plan and Appendix C3 provides an example, which sets out the following key elements:

- details of the mining hazard
- a list of key sensitive receptors
- a list of risk events associated with the hazard
- performance standards
- controls to address hazard
- a residual risk assessment and rating
- monitoring.

Many mining hazards will be able to be managed by applying example controls published by ERR (refer to Appendix C4). These example controls have been developed to reflect acceptable industry practice for some hazards, where site-specific investigations and tailored controls are not required.

Appendix C4 provides example controls for:

- Dust and particulates
- Noise
- Erosion and sedimentation
- Soil biological activity
- Site access
- Fire
- Non-mineral waste
- Weeds and pests
- Water
- Imported materials
- Vehicle sediment transport.

You are encouraged to include applicable example controls in your risk treatment plan(s), and to supplement these controls where necessary to minimise your risk rating as far as reasonably practicable.

If your mining hazards are more complex (e.g. blasting, slope instability), they may require technical investigations to develop site-specific controls.

4.4 Community engagement

You have a duty to consult with the community under section 39A of the MRSDA throughout the period of the mining licence.

The objective of your engagement with the community and stakeholders is to ensure that interested parties are informed of your proposed activities and given the opportunity to express how they may be affected. Community and stakeholder engagement is considered fundamental in determining agreed environmental outcomes. Early and continuous community and stakeholder engagement also enables you to understand and manage community and stakeholder expectations and mitigate potential risks which could impact your project.

Your work plan must include a community engagement plan that achieves these objectives. It should be proportionate to the site-specific conditions such as scale, operational activities, and the size and proximity of local communities.

The community engagement plan should include:

- a list of relevant community members and stakeholders
- a description of likely attitudes and expectations
- potential impacts on each of the identified community members/stakeholders
- how community members/stakeholders will be engaged (and at what level)
- a description of your proposed complaint/community feedback handling process, including when and how ERR will be notified
- a timeline for engagement throughout mine life.

For more information on community engagement, refer to ERR's guidelines at http://earthresources.vic.gov.au/earth-resources-regulation/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/community-engagement-guidelines-for-mining-and-mineral-exploration

4.5 Rehabilitation

Planning for what rehabilitation should be undertaken at what stage, is a critical component of managing a mining project. Nationally and internationally, industry-leading practice requires that rehabilitation planning should start before works commence and should continue throughout the life of the mine until final closure and relinquishment.

Closure planning is the objective of Regulation 43 of the Regulations, which specifies that a rehabilitation plan must be included in the work plan.

The rehabilitation plan should include:

- rehabilitation strategy and concept (e.g. security of the site, removal of plant and equipment)
- key assumptions (e.g. water availability, material balance)
- post-relinquishment land uses (e.g. open space parkland, grazing)
- an outline of key rehabilitation activities for each aspect (or domain) of the mine to meet the objective of safe, stable, and sustainable
- rehabilitation risks and their controls (management and mitigation measures).
- Note that new rehabilitation plan requirements will commence from 1 July 2020.

5. What needs to be in a work plan variation?

5.1 Work plan variation objectives

Submission of a work plan variation serves two objectives:

1. **Assessment**: It allows ERR to assess whether your work plan variation should be approved and, if so, any conditions that need to be applied.
2. **Compliance**: It sets out the scope of the approved works and any requirements you must meet, including monitoring and reporting obligations. It is important that these requirements are clearly described in your work plan variation as any ambiguity could result in you inadvertently breaching the MRSDA.

To achieve these objectives all applications to vary a work plan must include the following key components, as required by Regulation 48 of the Regulations:

Table 2: Key components of a work plan variation

Component	Work plan variations
Description of how the proposed variation relates to the current approved work plan.	A description limited to the new or changing works and its setting within your licence boundary.
Description of new or changed mining hazard arising from the proposed changes to the work set out in the work plan that increases the risk to the environment, to any member of the public, to land, property or infrastructure (known as 'mining hazard').	A description of the mining hazards resulting from the new or any change in works.
Description of the proposed change(s) to the risks and risk management plan as a result of the new or changing works.	Consideration of the risks associated with the new or changing works. Updates to your risk management plan to cover the new or changing works, which includes new or updated risk treatment plan(s) associated with the new or changed risks.
Community engagement plan	A plan that outlines plans for engagement with any community member or stakeholder impacted by the new or change in works.
Rehabilitation plan	Updates to your rehabilitation plan as required by the new or change in works.

The information that you need to provide to ERR to meet these requirements is outlined in the following sections:

5.2 A description of the proposed variation

The aim of the description of the proposed variation is to define the nature and scale of the new or changing mining activities in sufficient detail to:

- set the scope of the approved works
- enable the assessment and management of any mining hazard(s).

The description of the proposed variation must include:

- the location of the new or changing works within your licence boundary
- the location of sensitive receptors relevant to the new or changing works
- the nature of the new or changing works proposed and how they relate to the existing approved work plan
- the nature of any new auxiliary works (e.g. dewatering bores, water treatment plant).

Appendix B provides guidance on how you should describe these aspects to comply with Regulation 48 of the Regulations.

> If the required information is not included, ERR may request changes to your work plan variation, or refuse it. It is essential that all required information is provided to enable an efficient assessment process.

5.3 Risks from proposed works

Your work plan variation must identify and assess all risks that the new or changing works may pose to the environment, to the public, or to nearby land, property or infrastructure (known as **mining hazards**).

The identified risks then must be eliminated or minimised as far as reasonably practicable with risk treatment plan(s) that specify the measures you will use to eliminate or minimise those risks and monitor performance.

This section provides guidance on the identification, assessment and control of risks associated with proposed variations to works. Further information about the risk assessment process and risk document templates are provided in Appendices A and C respectively.

Figure 4 provides a summary of the risk assessment process that you must undertake when preparing a work plan variation.

Figure 4: Risk assessment process for work plan variations

5.3.1 Identification of mining hazards

You must identify the mining hazards that may be relevant to the proposed new or changing mining activities in accordance with the requirement of Regulation 48 of the Regulations.

For each relevant mining hazard, a **risk event** or risk events should be described and identified based on the description of the new or changing works. For example, dust may be identified as a hazard relevant to your proposed new or changing works. There may be one or many risk events associated with this hazard. A risk event associated with the dust hazard could be "unacceptable dust emissions generated at the licence boundary."

For each risk event you must also identify the consequence(s) for public safety, the environment, public infrastructure, private infrastructure and community facilities (i.e. the sensitive receptors), should that risk event occur. Sensitive receptors may be located either inside (e.g. heritage, artefact) or outside (e.g. waterways, public roads, fauna) the licence boundary and the pathway from the source of the risk event clearly shown.

During the risk assessment process, you must identify:

- the severity of the consequence(s) – i.e. harm or damage to the environment, to any member of the public, or to land, property or infrastructure due to your new or changing work
- the likelihood of the risk event occurring.

Appendix A provides guidance on the suggested risk assessment process.

5.3.2 Inherent and residual risk

During the risk assessment process you will produce a **risk register** that describes and collates the identified risk events, likelihoods and consequences associated with your work plan variation. These are called **inherent risks** and should be based on the description of the proposed variation.

Effective risk management requires that all risks are eliminated or reduced as far as reasonably practicable. Therefore controls should be identified and applied to each risk to achieve this. This information, including any risks eliminated, should be recorded in the risk register and risk treatment plans. For risks which are inherently **Low**, and which cannot be eliminated, the explanation of why they are **low** should be captured based on the project description.

The risk assessment process should then be conducted again, assuming implementation of the identified risk controls. The new likelihoods and consequences should produce a lower risk rating, these are the **residual risks** and should be based on the project description and listed controls. Where a **residual risks** are above medium, additional controls will need to be identified to reduce the risks to an acceptable level.

Both inherent and residual risk ratings should be included in your risk register. An example risk register is provided at Appendix C1.

5.3.3 Risk management plan

Your **risk management plan** should describe and address each mining hazard relevant to your project and the risk controls for all identified risks (i.e. **risk treatment plans**). The plan should also demonstrate that the control(s) are able to reduce either the likelihood(s) and/or consequence(s) such that the residual risk is minimised *as far as reasonably practicable*.

The risk management plan should include:

- a summary of the project, including assumptions and sensitive receptors
- a description of the risk assessment process conducted
- a risk register
- risk treatment plan(s).

Appendix C2 provides a template risk treatment plan and Appendix C3 provides an example, which sets out the following key elements:

- details of the mining hazard
- a list of key sensitive receptors
- a list of risk events associated with the hazard
- compliance standards
- controls to address the hazard
- residual risk assessment and rating
- monitoring.

Many mining hazards will be able to be managed by applying example controls published by ERR (refer to Appendix C4). These example controls have been developed to reflect acceptable industry practice for some mining hazards, where site-specific investigations and tailored controls are not required.

Appendix C4 provides example controls for:

- Dust and particulates
- Noise
- Erosion and sedimentation
- Soil biological activity
- Site access
- Fire
- Non-mineral waste
- Weeds and pests
- Water
- Imported materials
- Vehicle sediment transport.

You are encouraged to include applicable example controls in your risk treatment plan(s), and to supplement these controls where necessary to minimise your risk rating as far as reasonably practicable.

If your mining hazards are more complex (e.g. blasting, pit or underground instability), they may require technical investigations to develop site-specific controls.

5.4 Community engagement

You have a duty to consult with the community throughout the period of the mining licence under section 39A of the MRSDA.

The objective of your engagement with the community and stakeholders is to ensure that interested parties are informed of the new or changing mining activities and given the opportunity to express how they may be affected. Community and stakeholder engagement is considered fundamental in determining agreed environmental outcomes. Early and continuous community and stakeholder engagement also enables you to understand and manage community and stakeholder expectations and mitigate potential risks which could impact your project.

Your work plan variation must include an updated community engagement plan that achieves these objectives. It should be specific to the new or changing works and be proportionate to the site-specific conditions such as scale, operational activities, and the size and proximity of local communities.

The updated community engagement plan should include:

- a list of relevant community members and stakeholders
- a description of likely attitudes and expectations
- potential impacts on each of the identified community members/stakeholders
- how community members/stakeholders will be engaged (and at what level) for the new or changing works
- a description of your proposed complaint/community feedback handling process, including when and how ERR will be notified
- a timeline for engagement throughout mine life.

For more information on community engagement, refer to ERR's guidelines at http://earthresources.vic.gov.au/earth-resources-regulation/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/community-engagement-guidelines-for-mining-and-mineral-exploration

5.5 Rehabilitation

Planning for what rehabilitation should be undertaken at what stage, is a critical component of managing any mining project. Nationally and internationally, industry-leading practice requires that planning for rehabilitation should start before works commence and should continue throughout the life of the mine until final closure and relinquishment.

For a work plan variation, you should consider whether the new or changing works require a modification or addition to your rehabilitation plan.

If required, your work plan variation must include an updated rehabilitation plan which demonstrates any changes to the closure strategy as a result of the new or changing works. The updated rehabilitation plan must meet the requirements of Regulation 48 of the Regulations. Note that new rehabilitation plan requirements will commence from 1 July 2020.

Your updated rehabilitation plan should include:

- rehabilitation strategy and concept (e.g. security of the site, removal of plant and equipment)
- key assumptions (e.g. water availability, material balance)
- post-relinquishment land uses (e.g. open space parkland, grazing)
- an outline of key rehabilitation activities for each aspect (domain) of the mine to meet the objective of safe, stable, sustainable and visual acceptable
- rehabilitation risks.

6. What is the assessment process?

6.1 Assessment steps

The steps for assessment of a work plan (or work plan variation) are outlined in Table 3. Pathway A or B, is where:

A. mining activities are compliant with a current planning permit for the site or only need secondary consent under an existing planning permit; or

B. mining activities require a planning permit (or planning permit amendment).

Table 3: Assessment steps

Step		A Existing planning permit or secondary consent	B New planning permit (or amendment) required
1	You submit the work plan or work plan variation to ERR via RRAM	**Yes**	**Yes**
2	A fee is payable for submitting the plan (unless the Department Head has directed you to apply for a work plan variation)	**Yes** (go to step 8)	**Yes**
3	ERR has 28 days to assess the plan and: a. require changes; or b. refuse the plan; or c. refer it to a referral authority.	**No**	**Yes**
4	If ERR requires changes to the plan, you must make the changes and return the plan to ERR. Step 3 repeats after the changed plan is received.	**No**	**Yes**
5	Once satisfied that the plan meets statutory requirements, ERR refers the plan to a referral authority. The referral authority has 30 days to: a. not object to statutory endorsement; or b. not object to statutory endorsement if the plan is made subject to conditions; or c. object to statutory endorsement on any specified ground.	**No**	**Yes**
Note: *Should a referral authority fail to respond within 30 days, it is considered to not object to the statutory endorsement of the plan.*			
Note: *ERR cannot make a decision regarding statutory endorsement of the plan which is inconsistent with the advice of a referral authority.*			
6	ERR decides within 28 days of receiving a referral authority response whether to give the plan statutory endorsement, or refuse the plan.	**No**	**Yes**
7	Once the plan has statutory endorsement, you apply to the relevant council for a planning permit. The Victoria Planning Provisions require an application for a planning permit to be accompanied by a copy of a plan that has received statutory endorsement under Part 6B of the MRSDA (Department Head endorsement of work plan or variation to approved work plan).	**No**	**Yes**
8	You advise ERR that planning requirements are satisfied. ERR then has 28 days to: a. approve the work plan with or without conditions; or b. require changes; or c. refuse the plan.	**Yes**	**Yes**

6.2 Post-approval steps

If your work plan (or work plan variation) is approved, you will receive:

1. a letter – DJPR letter from ERR with advice of the approval and next steps, including:
   - information about the rehabilitation bond assessment process
   - an application for licence (for work plans)
2. a statement of reasons – attachment to the letter which provides details on the reasons for the decision
3. conditions – a full list of conditions for approval
4. your work plan – stamped and signed.

7. What is the work plan notification process?

7.1 Background

If you have an approved work plan, a **notification** (administrative update) may be considered for new or changing work where:

- There is **no significant increase** in risk arising from the new or changing work
- Council has been consulted and confirms in writing that the new or changing work does not require an amendment to the planning permit
- Relevant referral agencies have been consulted and confirmed that the new or changing work can be categorised as **low** or **medium** risk.

A '**significant increase in risk**' is where the residual risk (assessed under ERR's risk matrix in Appendix A of this guideline) is categorised as greater than **medium** after factoring in the adequacy of existing controls and the proposed application of additional controls (where these additional controls are listed in guidance material published by ERR, such as those in Appendix C of this guideline).

A list of new or changing works that may be suitable for a notification is provided at Appendix D.

It is recommended that you seek guidance from ERR before preparing a notification to determine whether a notification is appropriate.

7.2 Pre-submission

7.2.1 Assessing risk

Before submitting a notification, you should identify and assess the risk (likelihood and consequence) associated with the new or changing work. The residual risk should be assessed based on the application of existing controls (i.e. those under an approved work plan or work plan variation) and any example controls provided in Appendix C4 of this guideline. Where all residual risks associated with the new or changing work is assessed as **low** or **medium**, then a notification may be appropriate.

7.2.2 Consultation with council

You are required to consult with council to confirm that a variation to the planning permit is not required for the new or changing work. Confirmation from council that no change to the planning permit is required must be provided to ERR with the notification submission.

If an amendment to your planning permit is required, a work plan variation will need to be submitted to ERR instead of a notification. This is because a statutorily endorsed work plan is required to amend the planning permit.

7.2.3 Consultation with other agencies and regulators

Before submitting a notification, you should consult with other agencies and regulators regarding the new or changing work if it is within their jurisdiction. These other agencies and regulators could include catchment management authorities, the EPA, the Department of Environment, Land, Water and Planning and other government departments.

You should provide written confirmation from the relevant agencies and/or regulators that they agree that the new or changing work is low or medium risk and suitable to progress as a notification.

7.3 Submission

When a notification is submitted, ERR will review the new or changing work proposed, confirm the assessment of low or medium residual risk and note the supporting documents from council, other agencies and regulators.

ERR may require you to submit further information or evidence of consultation with these stakeholders.

7.4 Acknowledgement

If accepted, ERR will acknowledge the notification in writing.

7.5 Compliance

Accepted notifications will be included in your work plan for any site audits conducted by ERR during compliance activities.

If you are working outside of the approved notification then you are working outside of your work plan, which is an offence under the MRSDA. In such circumstances ERR has the power to stop work on the site and require the submission of a work plan variation.

Appendices

Appendix A
Risk assessment process

A1 Introduction

The risk assessment process undertaken must be documented in your risk management plan. This is to ensure that all mining hazards have been identified, and associated controls implemented to reduce the risk of harm or damage to the environment, any member of the public, to land, property or infrastructure in the vicinity of your work.

There are three important elements to understand when developing and implementing your risk management plan:

1. A hazard is an activity that poses risk at any time during the life of the mine, including set up/construction, operations/production and rehabilitation/closure.
2. Risk is the possibility of harm or damage that could happen as a result of an event. The level of risk is influenced by two factors, consequence and likelihood.
   a. Consequence is the outcome or impact of an event
   b. Likelihood is the probability of that event occurring.
3. A control is something which eliminates or reduces the consequence and/or likelihood of a risk. Controls can include work processes, engineering measures, and/or equipment.

For each relevant mining hazard, a **risk event(s)** should be identified and described based on the project description (or the description of the proposed variation for a work plan variation). To assess the significance of a risk, its risk rating must be determined by considering its consequence and likelihood.

A2 Consequences

Consequence is the severity of harm the risk event could cause when it occurs. The following questions may assist in establishing the consequences of a risk event:

- What kinds of harm could be caused?
  - A risk event may impact on more than one of the sensitive receptors under consideration: any member of the public, land, property and infrastructure or the environment.
- What factors could influence the severity of harm?
  - The consequence of a risk may vary under different circumstances. For example, weather conditions may increase the consequences of the risk event.
- In what ways could any member of the public be harmed?
- In what ways could any land, property or infrastructure be harmed?
- In what ways could the air, water, soil, vegetation, or flora and fauna species be harmed?

Under the MRSDA ERR has a duty when determining the consequence of a risk event to consider the potential impacts to:

- Members of the public:
  - Public health, safety, amenity and Aboriginal heritage
- Land, property and infrastructure:
  - Neighbouring property, land use and nearby infrastructure such as highways, transmission lines, pipelines, schools and hospitals
- Environment:
  - Air, water, soil, vegetation, and flora and fauna species

The descriptions of the consequence criteria that ERR uses to assess the harm caused by a risk event are provided in Table A1.

Table A1: ERR consequence descriptions

Severity	Consequence for "any member of the public" – public health, safety, amenity and Aboriginal heritage	Consequences for "land, property and infrastructure" *beyond the boundary of the licence area*	Consequences for "the environment" – air, water, soil, vegetation, flora and fauna species *other than for planned and approved disturbances within the licence area*
Critical Hazard has critical impact, in terms of severity and/or duration. Treatment or remediation effort is required, although some effects may be irreversible. Remediation of environmental contamination would require significant private and public resources. Hazard event would be the subject of widespread community outrage.	**Public health and safety:** One or more fatalities or life-threatening injuries or illness. Public exposed to a severely debilitating chronic health impact or life-threatening hazard. One or more injuries resulting in permanent disablement. **Public amenity:** Community or multiple individuals continuously experience major losses of amenity from dust, odour, fumes, noise, or other similar hazards over periods of weeks or longer. **Aboriginal heritage:** Harm to features and/or places of Indigenous cultural value. **Heritage:** Irreversible damage, or destruction of a place, object or historical archaeological site listed on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay.	**Land and land uses:** Permanent loss of production from primary production land >10 ha. Loss of annual-seasonal primary production from >100 ha of land. Irreversible or long-term environmental damage (with rehabilitation taking years or longer) to >1 ha of National Park or other conservation reserve. **Public and private property:** Total damage to private or public property or infrastructure or loss of income resulting from this damage >$10 million. Total loss of value of private property equivalent to >$10 million. **Services provided by infrastructure:** Important community services (e.g. transport, energy, health, telecommunications, education, water) suspended or significantly disrupted for extended period (weeks or longer).	**Environmental contamination event:** Environmental contamination event (of air, soil-land and/or water) of a magnitude that a State-level incident response is required. Incident response, clean-up and rehabilitation expected to run for years and/or cost ≥$10 million. **Native vegetation, flora species or fauna species:** Environmental contamination event or other form of environmental damage leading to bioregional, State or national extinction of listed threatened species of native flora or fauna or vegetation community. Irreversible or long-term (years) damage or environment harm to ≥10 ha of native vegetation (not listed threatened vegetation community) or to ≥1 ha listed threatened native vegetation community. Deaths of hundreds (or more) of listed native flora or fauna species or native mammals. Contamination or other environmental damage leading to deaths of native fauna well beyond (>1 km) the boundaries of the operation. **Surface water or groundwater:** Contamination of surface water/groundwater aquifer leading to disruption of beneficial uses as defined by SEPP (Waters) for more than year.

Severity	Consequence for "any member of the public" – public health, safety, amenity and Aboriginal heritage	Consequences for "land, property and infrastructure" *beyond the boundary of the licence area*	Consequences for "the environment" – air, water, soil, vegetation, flora and fauna species *other than for planned and approved disturbances within the licence area*
Major Hazard has major impact, in terms of severity, duration and/or frequency of occurrence. Treatment or remediation effort is required. Some effects may be irreversible. Remediation of environmental contamination would require significant private and public resources. Hazard event would be the subject of widespread community concern.	**Public health and safety:** One or more injuries or illness requiring surgery or resulting in long-term disablement. Public exposed to a hazard that results in hospitalisation for treatment from injury or illness. **Public amenity:** Community or multiple individuals regularly experience (weekly-monthly basis) major losses of amenity due to dust, odour, fumes, noise, or other similar hazards for multiple days on end. **Heritage:** Damage to a place, object or historical archaeological site listed on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay. Removal or relocation of elements associated with places, objects or historical archaeological sites.	**Land and land uses:** Permanent loss of production from primary production land <10 ha. Loss of annual-seasonal primary production from 10–100 ha of land. Irreversible or long-term environmental damage to <1 ha of National Park or other conservation reserve or to ≥10 ha of other public land. Reversible damage to ≥1 ha of National Park or other conservation reserve or to ≥10 ha of other public land. **Public and private property:** Total damage to private or public property or infrastructure or loss of income resulting from this damage $1–10 million. Total loss of value of private property equivalent to $1–10 million. **Services provided by infrastructure:** Important community services (e.g. transport, energy, health, telecommunications, education) suspended or significantly disrupted for days or experiencing minor disruptions for long periods (weeks or longer).	**Environmental contamination event:** Environmental contamination event (of air, soil-land and/or water) of a magnitude that would necessitate a regional emergency management incident response. Clean-up and rehabilitation expected to run for months and/or cost $1–10 million. **Native vegetation, flora species or fauna species:** Environmental contamination event or other form of environmental damage leading to local extinction of listed threatened species of native flora or fauna or vegetation community. Deaths of up to ~100 listed threatened flora or fauna species or native mammals. Major damage or environment harm to 1–10 ha of native vegetation (not listed threatened vegetation community) or to <1 ha listed threatened native vegetation community that will be irreversible or take years to recover from. **Surface water or groundwater:** Contamination of surface water/groundwater aquifer leading to disruption of beneficial uses as defined by SEPP (Waters) for up to one year.

Severity	Consequence for "any member of the public" – public health, safety, amenity and Aboriginal heritage	Consequences for "land, property and infrastructure" *beyond the boundary of the licence area*	Consequences for "the environment" – air, water, soil, vegetation, flora and fauna species *other than for planned and approved disturbances within the licence area*
Moderate Hazard has moderate, noticeable impact, in terms of severity, duration and/or frequency of occurrence. Moderate treatment or remediation effort may be required. Hazard event would be the subject of limited community concern.	**Public health and safety:** One or more injuries or illness requiring treatment by a physician or hospitalisation. Public exposed to a hazard that results in injuries or health effects requiring treatment by a physician. **Public amenity:** Community or multiple individuals regularly (weekly-monthly basis) experience significant loss of amenity from dust, odour, fumes, light, noise, vibration or other similar hazards. **Heritage:** Works to a place, object or historical archaeological site that will not alter the cultural significance as stated on the Commonwealth National Heritage List, Victorian Heritage Register, Victorian Heritage Inventory, or local Heritage Overlay.	**Land and land uses:** Loss of annual-seasonal primary production from <10 ha of land. Short-term (days-weeks) disruption to 10–100 ha of primary production land. Reversible damage to <1 ha of National Park or other conservation reserve or to <10 ha of other public land. **Public and private property:** Individual hazard event causes total damage to private or public property or infrastructure or loss of income resulting from this damage $50k–$1 million. Individual hazard event causes total loss of value of private property equivalent to $50k–$1 million. **Services provided by infrastructure:** Important community services (e.g. transport, energy, health, telecommunications, education) suspended or significantly disrupted for up to 1 day or experiencing minor disruptions for weeks.	**Environmental contamination event:** Environmental contamination event (of air, soil-land and/or water) with clean-up and rehabilitation expected to run for weeks and cost $10k–$1 million. **Native vegetation, flora species or fauna species:** Environmental contamination event or other form of environmental damage leading to deaths of a small number of listed threatened flora or fauna species or native mammals. Reversible damage or environmental harm to <10 ha of non-listed native vegetation community or <1 ha of listed native vegetation community. **Surface water or groundwater:** Localised contamination of surface water/groundwater aquifer leading to disruption of beneficial uses as defined by SEPP (Waters) for weeks to months.

Severity	Consequence for "any member of the public" – public health, safety, amenity and Aboriginal heritage	Consequences for "land, property and infrastructure" *beyond the boundary of the licence area*	Consequences for "the environment" – air, water, soil, vegetation, flora and fauna species *other than for planned and approved disturbances within the licence area*
Minor Hazard is perceived but has minor and typically temporary effects. Some remediation may be required.	**Public health and safety:** One or more injuries or illness requiring first aid treatment. Public exposed to a hazard that could cause injuries or adverse health effects requiring first aid treatment. **Public amenity:** Dust, odour, light, fumes, vibration or other similar hazards infrequently (no more than monthly) have a minor effect on the amenity of the community or individuals **Heritage:** Isolated damage to regionally or locally significant natural or historic heritage features that is readily rectified.	**Land and land uses:** Minor damage to agricultural land or public land not requiring active rehabilitation. Temporary and small-scale disruption to agricultural production (days, 1–10 ha). **Public and private property:** Total damage to private or public property or infrastructure $1–50k. Total loss of value of private property equivalent to $1–50k. **Services provided by infrastructure:** Important community services (e.g. transport, energy, health, telecommunications, education) suspended or significantly disrupted for short period (hours).	**Environmental contamination event:** Minor environmental contamination event (of air, soil-land and/or water). Clean-up and rehabilitation may be required, but can be completed within days. **Native vegetation, flora species or fauna species:** Minor damage or environment harm to <1 ha of native vegetation (not listed threatened vegetation community) that can be recovered in weeks to months. Minor contamination or other environmental damage that affects native fauna populations, but does not kill individuals or disrupt breeding or other important ecological processes. **Surface water or groundwater:** Minor contamination of natural waterway or wetland occurs, but water quality remains within applicable EPA or ANZECC guidelines for existing beneficial uses. Water extraction or diversion reduces surface water flows or groundwater available for environmental uses, but with no detectable effect on dependent species or ecosystems and carried out within terms of water licence.
Insignificant Impacts are barely recognised and/or quickly recovered from. No specific remediation required.	**Public health and safety:** An injury or ailment that does not require medical or first aid treatment. **Public amenity:** Dust, odour, light, fumes, vibration or other similar hazards infrequently (no more than monthly) contribute to a small reduction in the amenity of the community or individuals.	**Land and land uses:** Minor, temporary disruption to primary production (<days) from <1 ha of land. **Public and private property:** Total damage to private or public property or infrastructure <$1k. Total loss of value of private property equivalent to <$1k. **Services provided by infrastructure:** Important community services (e.g. transport, energy, health, tele-communications, education) maintained, but experiencing minor disruptions or delays.	Hazard event with minimal environmental impact and no noticeable effect beyond the immediate occurrence or expression of the hazard.

A3 Likelihood

The next step is to assess the likelihood of the risk event occurring and the associated consequence(s). Likelihood is based on what is known about the risk event and the way circumstances and activities affect the risk event and associated consequence(s).

The likelihood of a risk event occurring during the expected life of the operation is rated by ERR using the likelihood descriptions provided in Table A2.

Table A2: ERR likelihood descriptions

Severity	Description	Probability of event occurring
Almost certain	The risk event is expected to occur in most circumstances.	**90–100%**
Likely	The risk event will probably occur in most circumstances.	**70–90%**
Possible	The risk event might occur at some time.	**30–70%**
Unlikely	The risk event could occur at some time.	**5–30%**
Rare	Highly unlikely, but the risk event may occur in exceptional circumstances.	**0–5%**

In establishing the likelihood of an event, there are some key concepts to consider:

- Has there been a previous occurrence of this risk event?
  - Considering what has happened previously, such as incidents and near misses, can assist in establishing the likelihood. It is important not to just consider your business but think about occurrences across the industry.
- Are there any design features of your project that increase or decrease the likelihood of this risk event occurring?
  - Consider how effective these features are.
- Are you operating or environmental conditions likely to change?
  - Operating or environmental conditions change over time and vary throughout the year. These changes can influence the likelihood of a risk event occurring.
- How does people's behaviour effect the likelihood?
  - The way people act or behave can affect the likelihood of a risk event occurring. For example, they can make mistakes, misuse items or act spontaneously.

A4 Risk Rating

After considering the consequences and likelihood of the risk event, they are used together to determine the risk rating. The risk matrix below is used by ERR to determine the risk rating for each risk event. The purpose of rating risk is to guide decision making on risk management to eliminate or otherwise reduce the risk to an acceptable level.

Figure A1: ERR Risk Matrix

Likelihood						
	Almost Certain	Medium	High	Very High	Very High	Very High
	Likely	Medium	Medium	High	Very High	Very High
	Possible	Low	Medium	Medium	High	Very High
	Unlikely	Low	Low	Medium	High	High
	Rare	Low	Low	Medium	Medium	High
		Insignificant	Minor	Moderate	Major	Critical
		Consequence				

There may be multiple consequences for a single risk event. When this occurs, the highest risk rating (after assessment of consequence and likelihood for each consequence), should be used to categorise the risk rating of the risk event. For example, the risk event may have a consequence for a member of the public rated as **major** and with a likelihood of **rare**; a consequence of **moderate** for land, property and infrastructure and with a likelihood of **likely**; and a **minor** consequence for the environment and with a likelihood of **possible**. This results in individual risk ratings of **medium**, **high** and **medium** respectively. In this instance the overall rating for the risk event is **high**.

Once the risk rating has been established some risks will need to have controls in place to reduce them to an acceptable level. Higher risk levels should take priority. Table A3 provides guidance on what steps need to be taken depending on the risk rating.

Table A3: Risk Rating Acceptability

Risk level	Description
Very High	Totally unacceptable level of risk. Controls must be put in place to reduce the risk to lower levels.
High	Generally unacceptable level of risk. Controls must be put in place to reduce the risk to lower levels or seek specific guidance from ERR.
Medium	May be acceptable provided the risk has been minimised as far as reasonably practicable.
Low	Acceptable level of risk provided the risk cannot be eliminated.

Appendix B

B1 Mining documentation requirements

Table B1: Work plan requirements

Regulation	Required Item	Guidance
42	**Information required in work plans—mining work**	
42(a)	A description of sensitive receptors in relation to the environment, any member of the public, or land, property or infrastructure in the vicinity of the work.	Receptors are considered to be sensitive when they are located in the vicinity of the work. In the vicinity of the work is defined by referring to requirements of separation distances or buffer distances or other quantitative/qualitative references stipulated in legislation, policies, or guidance material relating to those receptors. Describe and specify the location of any residences, public facilities, roads, bridges, pipelines, power lines, easements, parks, reserves, waterways, depth to groundwater, heritage sites, communities or other sensitive receptors in the vicinity of the project area. Sensitive receptors may include (but not limited to): • Residential • Private properties • Community facility • Waterways • Groundwater bores • Groundwater dependant ecosystems • Areas of cultural heritage sensitivity • Significant landscape • Public infrastructure – such as bridges, roads, railways • Parks and reserves • Heritage buildings and features.
42(b)	A location map of the work plan area and areas within 2 km of the work plan area, drawn at an appropriate scale, that shows—	Maps need to be provided so that ERR can assess your proposal in the context of the surrounding site setting, including the identification of sensitive receptors. A series of maps can be prepared to best represent the proposal and information to be presented. The location map should be at a scale of 1:25,000 or at an appropriate scale for showing sensitive receptors within 2km of the proposed licence boundary and should include: • north direction, legend, bar scale, date of and revision date of drawing • boundaries of the proposed licence area (with distances and bearings, or GPS co-ordinates) • buffer radius (circles or elliptical) (at minimum 500m, 1km and 2km) from the proposed licence boundary • an outline of the Geotechnical Risk Zone (GRZ) and any natural and man-made sensitive receptors within the GRZ (refer to ERR Guidance Material for the Assessment of Geotechnical Risks in Open-Pit Mines and Quarries) • the proposed area of disturbance and area of mining.

Regulation	Required Item	Guidance
42(b)(i)	The location of sensitive receptors identified.	The identified sensitive receptors in 42(a) must be shown and labelled on the site maps.
42(b)(ii)	The extent and status of Crown lands and extent of private lands.	Include the extent of Crown lands, private lands, and private land allotments for the proposed work plan area; noting depth limitations if applicable. For Crown lands, display categories (where applicable) – Unavailable Crown land, Restricted Crown land, Unrestricted Crown land.
42(b)(iii)	Residential, commercial and industrial development	This detail can be shown as planning scheme zoning layers, or aerial photography and must be labelled to show the: • location of possibly occupied houses, and community facilities • location of townships, and cadastral boundaries • location of infrastructure, including major and minor roads (with names), bridges, rail lines, pipelines (water, gas, telecommunication), power lines, and easements.
42(b)(iv)	Public facilities and infrastructure.	This includes parks and reserves. This detail can be shown as aerial photography. All features must be labelled.
42(b)(v)	Rivers and streams.	The location of all waterways, and their names.
42(c)	A general description of geological information pertaining to the work, including— (i) stratigraphy; and (ii) any adverse geological structures; and (iii) the minerals to be extracted; and (iv) the estimated mineral resources and ore reserves.	• Describe the geology, geological structure (faults, fractures etc.) • Describe current and past land uses which may impact the proposed design (such as contaminated land, old tailings, underground voids) • Specify the resource type, e.g. gold • An estimate of total reserves within the licence boundary.
42(d)	A general description of the mine operations including—	A description of mine operations is essential to understanding the proposal and identifying the activities that will be undertaken.

Regulation	Required Item	Guidance
42(d)(i)	The method and scale of extraction.	• Provide a general description of extraction methods, including plant and equipment for extraction and haulage • Describe the proposed area and depth of extraction, proposed stages of extraction (if applicable), proposed design of extraction pit including number of benches and working and terminal slope configuration (slope, bench height, berm width). Describe depths and slopes for all parts of the extraction area (if variable) • Specify the total proposed area of disturbance (excavation, processing, roads, etc.) • Specify the volume of extraction excluding topsoil • For work plan variations, describe the current open area and the additional area to be opened • Specify whether any dewatering activities will be undertaken • Specify whether vegetation clearing will be undertaken • Specify whether any blasting activities will be undertaken and, if so, which blasting methods will be applied. Provide detail (days and time) of proposed blasting operations (where applicable). To support the proposal a cross-section of the pit design should be included. The cross-sections are to show geology, and batter design, with proposed bench heights, berm details and both working and terminal batters, for all parts of the extraction area. The cross-section must show elevation relative to sea level (mAHD).
42(d)(ii)	Ore processing methods and facilities.	Provide a general description of processing methods, including plant and equipment, and storage of clean water, process water and tailings.
42(d)(iii)	Waste disposal methods and facilities.	Describe physical and chemical composition of mine waste materials, identifying potential hazardous substances, including the presence of sulphides (if acid sulphate soil has been excavated and/or chemicals will be used in processing). This description is to include any added chemical treatments / flocculating agents. Describe how hazardous materials such as fuel and chemicals will be managed.
42(d)(iv)	Stockpiling facilities.	Specify general location, volume and height of topsoil, overburden, and product stockpiles. Describe the process for removal and stockpiling of topsoil.

Regulation	Required Item	Guidance
42(d)(v)	Other mine infrastructure.	Provide a general description of operational equipment to be used on site, including (but not limited to) operational equipment for extraction, processing (crushing, screening, gravity separation, wet separation, leaching, etc.), and haulage. Describe and show on the Site Layout Plan processes or equipment locations (such as processing plants next to an open pit) that may increase the potential for slope instability. Describe equipment to be used for dewatering (if applicable). Describe the number and location of any water bores and pumps. On a plan, show the location of any workshops, storage sheds, lunchroom, amenities block, site office, weighbridge, laboratory testing, training and meeting rooms, access and haul roads, parking, maintenance hardstand and vehicle wash down.

Regulation	Required Item	Guidance
42(e)	A site map, drawn at an appropriate scale, that shows— (i) the general layout of the mine, associated facilities and infrastructure; and (ii) cross-sections and, in the case of an underground mine, long sections of the proposed extraction area.	Maps need to be provided so as ERR can assess the proposal in the context of the surrounding site setting, including the identification of sensitive receptors. A series of maps can be prepared to best represent the proposal and information to be presented. The Site Layout Plan/s should include: • a scale of 1:1,000, 1:2,500 or other appropriate scale for showing sensitive receptors within the vicinity of the licence area, with northing, legend, bar scale, and drawing & revision dates • licence boundaries, extraction boundaries • cadastral boundaries and any depth limitations • existing surface contours, topographical features, drainage patterns, water courses (including drainage diversion, levee location and design) and vegetation to be removed/retained • plant and equipment (e.g. buildings & surface facilities, location of power generation and/or reticulation, offices & toilets) • extent of: – open cut extraction, with proposed bench heights, berm details and working batters; and/or – underground workings; • outline of the GRZ and any sensitive receptors within the GRZ (for open cut pits only) • sequence / staging / direction of pit extraction • representative cross-sections showing geology and working and terminal batter designs with proposed bench heights, berm details and batter slopes • proposals for landscaping of the licence area, including buffer zones and retained areas of native vegetation • adjoining public road(s), with names • a survey benchmark with a reduced level (if applicable) • access roads • location of water dams, in-pit sumps, slimes dams and pipe lines • location of onsite power lines, gas lines and any other easements • general location of stockpiles for topsoil, overburden and product • general location of any removed vegetation material (such as that to be used for rehabilitation) • location of fuel storage areas, including both above-ground and underground storage tanks • explosives, additives or hazardous waste storage areas • water bores and pumps (if any).
42(f)	In the case of an underground mine, a schematic and description of the workings of underground operations.	Underground Mines Only Provide a schematic and general description of underground operations.

Regulation	Required Item	Guidance
43	**Information required in work plans—rehabilitation plans**	
43(4)(a)	Concepts for the end utilisation of the mine site.	The concept plan should establish expected end use/s of the site and its general characteristics at the completion of rehabilitation. It may consider: • future land uses that do not depend on the need to obtain a planning permit for its use; if the proponent is proposing uses that require a planning permit, such as a land fill, a letter from the relevant waste management group should accompany the proposal (refer to ERR guidelines Imported Materials Management – include reference) • the capability/suitability of the land; describe the land's inherent features, to help demonstrate that the proposed end use is suitable • the possible end land use(s); provide a conceptual statement on final landform based on all available geological, geochemical and biological information • conceptual slope configuration • conceptual rehabilitation of waste dumps, stockpiles, water storages and slimes dam facilities • surface water management for runoff control and erosion prevention • the nature of soils and overburden/waste rock to be used in rehabilitation • evidence that there is sufficient suitable material available to complete the proposed final landform – such as materials balance • any constraints on final land use (e.g. regulatory, physical, agreements with private land owners) • overview of proposed action to confirm rehabilitation strategy with relevant stakeholders.
43(4)(b)	Proposals for the progressive rehabilitation, stabilisation and revegetation of extraction areas, waste disposal areas, stockpile areas, dams and other land affected by the mining work.	The progressive rehabilitation strategy should set out in some detail: • how a progressive rehabilitation strategy will deliver the final landform/land use outcomes • how progressive landscaping will be undertaken so that visual impact is minimised • the timeframe between establishing terminal slope and commencing progressive rehabilitation • the constraints that may limit progressive rehabilitation works • the approach to undertaking progressive rehabilitation (e.g. the availability of suitable material, landscaping, revegetation, the depth of soil stripping, the approximate depth of respread soil, proposed seedbed treatments and the reasons for their selection, proposed revegetation method and the general mix of species, stockpile dimensions) • monitoring and reporting arrangements for assessing and documenting the effectiveness of progressive rehabilitation • process for review and improvement of the Rehabilitation Plan, appropriate to the remaining life of the mining operation.

Regulation	Required Item	Guidance
43(4)(c)	Proposals for landscaping to minimise the visual impact of the mine site.	The rehabilitation plan should include proposals to minimise impacts to visual amenity as far as reasonably practicable during both progressive rehabilitation and final rehabilitation and closure.
43(4)(d)	Proposals for the final rehabilitation and closure of the mine site, including the security of the site and the removal of plant and equipment, taking into account any potential long-term degradation of the environment.	• The proposal for final rehabilitation plan should include: • the timeframe for completing final rehabilitation and closure of the site • whether the proposed final land use is sympathetic to the surrounding landscape (e.g. analysis of the visual impact from critical views) • how proposed final land form may impact on the long-term surface water/groundwater regime • how final security of the work authority area (e.g. water dams/slimes dams etc.) is to be achieved • the proposed rehabilitation method of any mine features (e.g. slimes dams etc.) to ensure the long term physical and chemical integrity of these, including the management of erosion, seepage and potential exposure to contamination • the proposed general plans for the removal of plant and equipment including: – demobilisation of mobile plant, railways, conveyors and temporary facilities – decommissioning of fixed plant, including the removal and disposal of hazardous materials – demolition, refurbishment or reutilisation of buildings or facilities, including description of expected waste and disposal methods • whether permits or approvals from other agencies will be required for the final land use or rehabilitation design • objectives and acceptance criteria to demonstrate achievement of proposed final land use over an appropriate time-frame • proposals for short and long-term monitoring and reporting to be undertaken to demonstrate achievement of final land use.
44	**Information required in work plans—identification of hazards and risks**	
44(a)	If exploration work is to be carried out under the licence, details of exploration hazards that may arise from the exploration work.	For requirements, refer to the guidance in Section 4.3 of the document above.
44(b)	If mining work is to be carried out under the licence, details of mining hazards that may arise from the mining work, including mining hazards arising from— (i) set up or construction; and (ii) operations or production.	For requirements, refer to the guidance in Section 4.3 of the document above.
44(c)	Details of the rehabilitation hazards that may arise from rehabilitation under the licence.	For requirements, refer to the guidance in Section 4.3 of the document above.

Regulation	Required Item	Guidance
44(d)	An explanation of how the identified hazards may harm or damage the sensitive receptors described in the work plan, including evidence to support the assessment of the potential for harm or damage to be caused.	For requirements, refer to the guidance in Section 4.3 of the document above.
44(e)	An assessment of the risks that the identified hazards may pose to identified sensitive receptors, having regard to— (i) the nature of the hazard; and (ii) the likelihood of the hazard causing, or contributing to, any harm or damage; and (iii) the severity or consequence of the harm or damage that may be caused.	For requirements, refer to the guidance in Section 4.3 of the document above.
45	**Information required in work plans—risk management plan**	
45	A risk management plan that sets out what the licensee will do to eliminate or minimise the identified risks as far as reasonably practicable.	For requirements, refer to the guidance in Section 4.3 of the document above.
45(a)	Measures to be applied to eliminate or minimise the risks as far as reasonably practicable.	For requirements, refer to the guidance in Section 4.3 of the document above.
45(b)	The performance standards to be achieved by either individual measures or some combination of measures.	For requirements, refer to the guidance in Section 4.3 of the document above.
45(c)	Management systems, practices and procedures that are to be applied to monitor and manage risks and compliance with performance standards.	For requirements, refer to the guidance in Section 4.3 of the document above.
45(d)	An outline of the roles and responsibilities of personnel accountable for the implementation, management and review of the risk management plan.	For requirements, refer to the guidance in Section 4.3 of the document above.

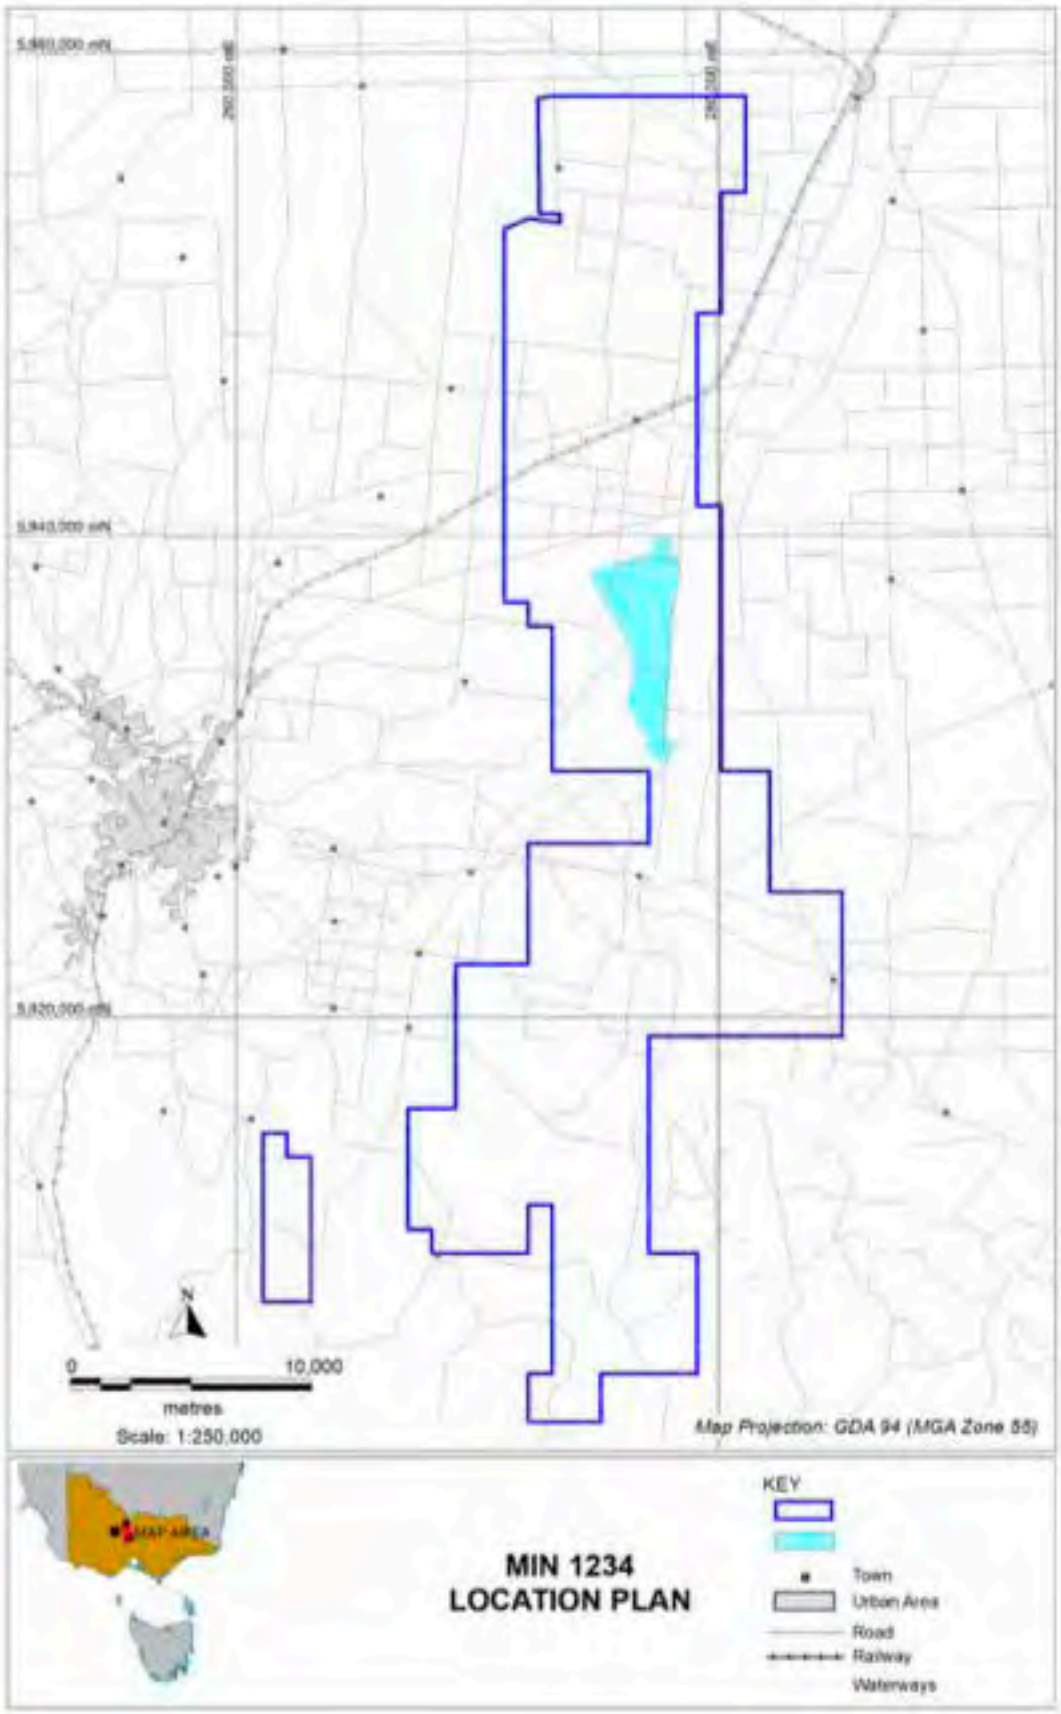
Regulation	Required Item	Guidance
46	**Information required in work plans—community consultation**	
46	A community engagement plan that:	The proponent has a duty to consult with the community under section 39A of the MRSDA throughout the period of the mining licence. The required consultation provides valuable information that contributes to the community engagement plan. The community engagement plan (CEP) should be proportionate to the site-specific conditions such as scale, operational activities, and the size and proximity of local communities. A CEP is to include: • a title page that includes the report name, date, and author's name and contact details • a table of contents and sub-headings • a brief overview of the proposed operations associated with the Work Authority • maps consistent with the requirements outlined in Regulation 42 of the Regulations. For more information, refer to the ERR guidelines *Community Engagement Guidelines for Mining and Mineral Exploration in Victoria*.
46(a)	identifies the community likely to be affected by the work under the licence; and	Include a list of the community and any other stakeholders likely to be affected by the proposed operations, and/or interested in the proposed operations, including landholders, land owners, local government, community groups and Crown land managers.
46(b)	sets out how the licensee will share information with the community; and	Include: • how each of the identified community members/stakeholders will be engaged (and at what level) • proposed information channels/types for the community (newsletters, meetings, facilitated events, web content, social media, dedicated contact person etc.)
46(c)	sets out how the licensee will receive feedback from the community; and	Include proposals for mechanisms to receive and collect feedback about the operations from the community (online, meetings, phone calls etc.)
46(d)	sets out how the licensee will manage complaints and other communications from members of the community; and	Include proposals for mechanisms to manage complaints and other communications about the operations from the community (online, meetings, phone calls etc.)
46(e)	In the case of a work plan for a mining licence that covers an area of more than 5 hectares, sets out how the licensee will—	
46(e)(i)	Identify community attitudes and expectations.	A community engagement plan is to include: • a description of how community attitudes and expectations have been and/or will be identified and documented • a description of likely community and stakeholder attitudes and expectations related to the proposed operations • the potential impacts on each of the identified community members/stakeholders.

Regulation	Required Item	Guidance
46(e)(ii)	Analyse community feedback, taking into account community concerns or expectations.	Include how community feedback will be captured, registered, assessed and responded to (a register or similar that demonstrates how this will be managed) (provide an example)
46(e)(iii)	Register, document and respond to complaints and other communications from members of the community in relation to the mine operations.	Include a description of the proposed complaint/ community feedback handling and response process, including when and how ERR will be notified
48	**Information required in application for variation of work plan**	
48(1)(a)	If changes to the work or rehabilitation set out in the work plan are proposed, a description of any new or changed exploration hazard, mining hazard or rehabilitation hazard arising from the proposed changes that significantly increases the risks posed to— (i) the environment; or (ii) any member of the public; or (iii) land, property or infrastructure in the vicinity of the work or rehabilitation relating to the new or changed hazard.	Describe the proposed change to the work plan, and any new or changing hazard. This may include a change in direction of extraction, moving closer to sensitive receptors, or removal of native vegetation not previously approved.
48(1)(b)	If any new or changed hazard is described under paragraph (a), the information specified in regulations 44 and 45 that relate to the new or changed hazard, including the resulting proposed changes to the work plan.	The hazard assessment and risk management plan must meet the requirements set out in Regulations 44 and 45 of the Regulations. Refer to requirements for work plans in Table B1 above, and details provided in Section 5.3 of this guideline. This must include new or changing hazards as a result of the proposed change to operation.
48(1)(e)	If the application for the proposed variation is lodged on or after 1 July 2019 but before 1 July 2020 and includes new or changed rehabilitation of land disturbed by mining, the information specified in regulation 43(4) that relates to the new or changed rehabilitation, including the resulting proposed changes to the rehabilitation plan in the work plan.	The plan must describe the proposed changes to the rehabilitation plan and describe the planned rehabilitation for the whole site, including on maps and cross sections. The rehabilitation plan must meet the requirements set out in Regulation 43 of the Regulations. Refer to Section 4 of this guideline.

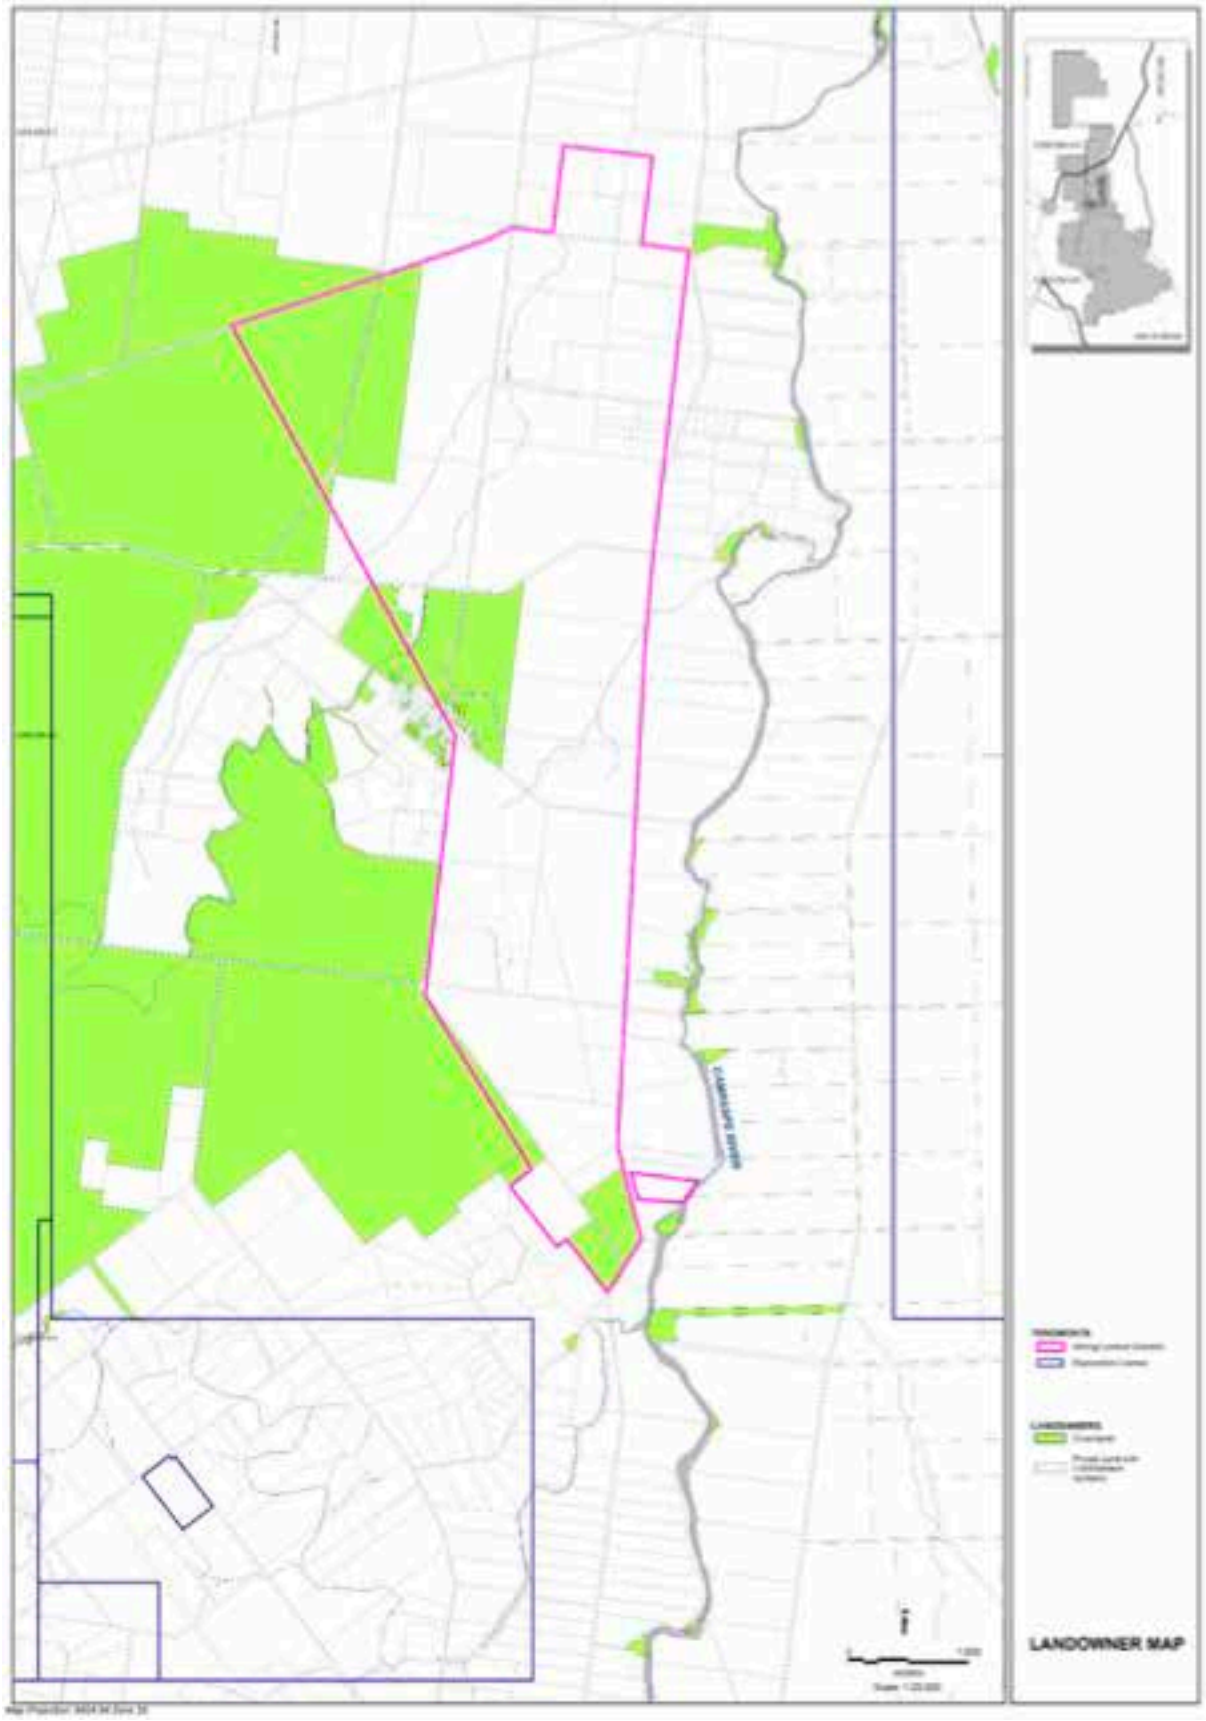
Regulation	Required Item	Guidance
48(1)(g)	If the proposed variation includes or gives rise to any changes relating to community consultation, the proposed changes to the work plan in relation to the information specified in regulation 46.	The community engagement plan must include a description of engagement for the planned changes, i.e. how the proposed changes will be communicated. The community engagement plan must meet the requirements set out in Regulation 46 of the Regulations. Refer to Section 4 of this guideline for information about work plan requirements.
48(1)(h)	If the proposed variation includes any new or changed work to be carried out at a declared mine, the information that relates to, and is applicable to, the proposed changes to the work plan in relation to the requirements and processes set out in Schedule 12.	Declared Mines Only Mining work being carried out on Declared mine sites must include consideration of relevant stability requirements set out in Schedule 12.
48(1)(i)	If the proposed variation includes any new or changed mining work that is the mining of coal, the information that relates to, and is applicable to, the proposed changes to the work plan in relation to the information specified in regulation 40(b)(iii).	Coal Mines Only Mining work being carried out on Coal mine sites must include consideration of relevant fire management plan requirements set out in Schedule 8.
48(1)(j)	A description of how the proposed variation to the work plan relates to the current approved work plan.	Provide summary of reason for plan, including reason for work plan variation, clear details of changes (e.g. change in lateral and vertical extent etc.) from the approved plan and relationship to the approved plan, in both the plan description and on supporting maps.

B2 Example site plans

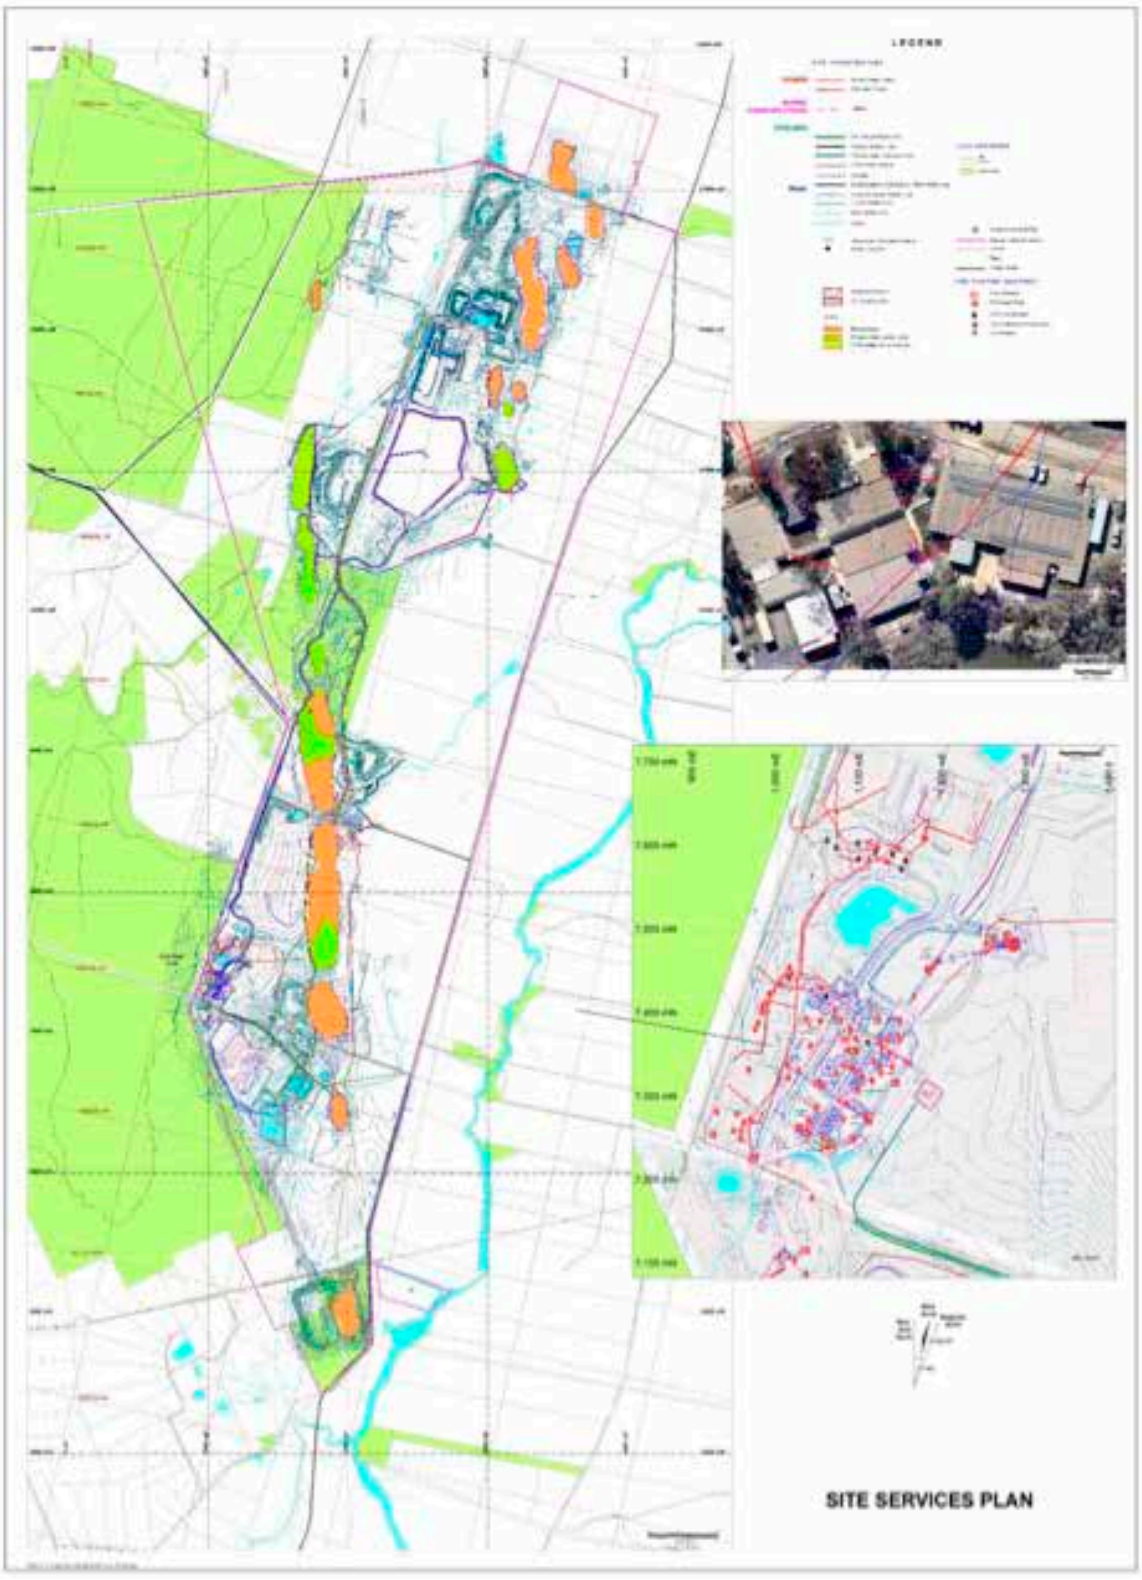
B2-1 – Example of a general location plan



B2-2 – Example of a land owner plan



B2-3 – Example of a site services plan



Appendix C

C1 Example risk register

C1.1 Inherent Risk

During the risk identification and assessment process you should produce a **risk register** that describes and collates the identified risk events, likelihoods and consequences associated with the proposed work plan (or work plan variation). These are called **inherent risks** and should be based on the project description in your work plan, or the project description of the proposed variation in your work plan variation.

Table C1-1: Example risk register showing inherent risk

Hazard	Risk No	Risk Event	Causes/ Background	Receptors	Risk assessment prior to additional risk controls (project inherent risk)		
					Likelihood	Consequence	Risk rating
	1				Rare	Insignificant	Low

Any inherent risks that you have assessed to have a risk rating of medium or above, according to the ERR risk matrix in Appendix A3, will require additional controls to either eliminate the risk or minimise its rating as far as reasonably practicable. Inherent risks that are ranked as Low should include an explanation of the relevant mine design aspects (as outlined in the project or proposed variation description) that result in that low risk rating.

C1.2 Residual Risk

The risk assessment process should then be conducted again, assuming implementation of the identified control(s) for the relevant risk events, with updated likelihoods and consequences. These are called **residual risks** and should be based on the project or proposed variation description and the listed controls.

Table C1-2: Example risk register showing inherent and residual risk

Hazard	Risk No	Risk Event	Causes/ Background	Receptors	Risk assessment prior to additional risk controls (project inherent risk)			Risk assessment after including risk controls (project residual risk)		
					Likelihood	Consequence	Risk rating	Likelihood	Consequence	Risk rating
	1				Rare	Insignificant	Low	Rare	Insignificant	Low

C1.3 Accountable Personnel

List personnel accountable for the implementation, management and review of the Risk Management Plan.

Table C1-3: Example accountable personnel

Personnel	Roles and Responsibilities

C2 Template risk treatment plan

Scope

This risk treatment plan is for the control of:

[Insert Hazard]

A mining hazard means any mining activity and circumstance that may pose a risk to the environment, to any member of the public or to land, property or infrastructure in the vicinity of work carried out at a mine.

Key sensitive receptors

Key sensitive receptors include the environment, any member of the public or land, property or infrastructure in the vicinity of a mine that may be impacted or put at risk by the hazard associated with the mining activity.

The key sensitive receptors associated with this hazard include:

#	Details of the sensitive receptor	Location and proximity to site	How hazard may harm or damage Sensitive Receptor	Evidence to support assessment
1				
2				
3				
4				
5				

[Add or delete rows from the above table as appropriate]

To determine the key sensitive receptors, consider:

- Members of the public – public health, safety, amenity and Aboriginal heritage
- Land, property and infrastructure: neighbouring property as well as nearby infrastructure such as highways, schools and hospitals
- Environment: air, water, soil, vegetation, flora and fauna outside the work area.

Risk events

These are the risk events associated with the hazard. Include an inherent risk rating for each event considering the design proposal of the project.

The project phase options include construction, operation and closure, or a combination. If you feel that the inherent risk for the same risk event will differ in different project phases, then list the risk event for each project phase.

[The likelihood and consequence should be assessed using the descriptors provided by Earth Resources Regulation and the risk rating determined using Earth Resources Regulation's risk matrix.]

#	Details of the risk event	Project phase	Consequence	Likelihood	Inherent risk rating
1					
2					
3					
4					
5					

[Add or delete rows from the above table as appropriate]

Objectives

The objectives are the key aims or goals of the control measures that will be out in place to eliminate or minimise, as far as reasonably practicable, the identified risk events.

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each objective does not need to relate to all of the control measures.]

[Insert Objective]

[Insert Objective]

[Insert Objective]

Compliance standards

The compliance standards are the key best practice standards or guidelines that will be achieved with the control measures in place. These best practice standards or guidelines may come from the EPA, State Environment Protection Policy or other regulatory agencies.

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each compliance standard does not need to relate to all of the control measures.]

The compliance standards for this risk treatment plan are:

[Insert Compliance Standard]

[Insert Compliance Standard]

[Insert Compliance Standard]

Acceptance criteria

The acceptance criteria are the measures by which the control measures will be deemed to be effective in achieving the objective and eliminating or minimising, as far as reasonably practicable, the identified risk events. The acceptance criteria could be to achieve a best practice standard (e.g. an EPA standard).

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each acceptance criteria does not need to relate to all of the control measures.]

The acceptance criteria for this risk treatment plan are:

[Insert Acceptance Criteria]

[Insert Acceptance Criteria]

[Insert Acceptance Criteria]

Controls to address hazard

The control measures are to be designed to eliminate or minimise, as far as reasonably practicable, the identified risk events. The numbers of the risk events being managed by each control should be recorded against the control along with how the control will be implemented.

[Examples are included in the guidance sheets for managing hazards.]

The controls for this risk treatment plan are:

#	Details of controls being used	Risk events being managed (number from above)	Performance standards/measures *(specifying how the control is being implemented – if not implicit in the control)*
1			
2			
3			
4			
5			

[Add or delete rows from the above table as appropriate]

Residual risk assessment

Considering the controls being put in place the assessment of the residual risk associated with the risk events identified for this hazard is shown in the table below.

[The likelihood and consequence should be assessed using the descriptors provided by Earth Resources Regulation and the risk rating determined using Earth Resources Regulation's risk matrix.]

#	Details of the risk event	Phase	Consequence	Likelihood	Residual risk rating
1					
2					
3					
4					
5					

[Add or delete rows from the table below as appropriate]

Monitoring

[List the monitoring of the status or effectiveness of the controls associated with this hazard. Include the aspect being monitored and the detail of the monitoring. Monitoring includes management systems, practices and procedures that are to be applied to monitor and manage risks and compliance with performance standards.]

#	Aspect to be monitored	Details of monitoring
1		
2		
3		

[Add or delete rows from the table below as appropriate]

Reporting

[List the reporting of the monitoring, effectiveness or status of the controls associated with this hazard. Include to whom the reporting will be provided, the frequency of the reporting and how it will be used.]

#	Aspect being reported	Who will the information be reported to and at what frequency?	How will it be used?
1			
2			
3			

[Add or delete rows from the table below as appropriate]

Relevant industry publications

[List any relevant industry publications that support the management and monitoring of this hazard]

#	Document	Source (e.g. URL, appendix number)
1		
2		
3		

[Add or delete rows from the table below as appropriate]

Operator's reference documents

[List any relevant manuals, procedures or other documents that support the management and monitoring of this hazard]

C3 Example risk treatment plans

Scope

This risk treatment plan is for the control of: *Dust*

A mining hazard means any mining activity and circumstance that may pose a risk to the environment, to any member of the public or to land, property or infrastructure in the vicinity of work carried out at a mine.

Key sensitive receptors

Key sensitive receptors include the environment, any member of the public or land, property or infrastructure in the vicinity of a mine that may be impacted or put at risk by the hazard associated with the mining activity.

The key sensitive receptors associated with this hazard include:

#	Details of the sensitive receptor	Location and proximity to site	How hazard may harm or damage Sensitive Receptor	Evidence to support assessment
1	Property	1km to the north west	Amenity	ERR consequence descriptors
2	Public Amenity		Amenity	ERR consequence descriptors
3				
4				
5				

[Add or delete rows from the above table as appropriate]

To determine the key sensitive receptors, consider:

- Members of the public – public health, safety, amenity and Aboriginal heritage
- Land, property and infrastructure: neighbouring property as well as nearby infrastructure such as highways, schools and hospitals
- Environment: air, water, soil, vegetation, flora and fauna outside the work area.

Risk events

These are the risk events associated with the hazard. Include an inherent risk rating for each event considering the design proposal of the project.

[The likelihood and consequence should be assessed using the descriptors provided by Earth Resources Regulation and the risk rating determined using Earth Resources Regulation's risk matrix.]

#	Details of the risk event	Phase	Consequence	Likelihood	Inherent risk rating
1	Generation of dust from plant and equipment	• Construction • Operation • Rehabilitation	Moderate	Almost Certain	Very High
2	Generation of dust from overburden dumps and stockpiles	• Construction • Rehabilitation	Moderate	Almost Certain	Very High
3	Generation of dust from imported fill material	• Operation	Moderate	Almost Certain	Very High

[Add or delete rows from the above table as appropriate]

Project design

What parts of the project design will impact these risks and potentially reduce the risk rating?

- The activity areas are generally surrounded by trees. The trees reduce the wind speed at ground level which reduces the risk of dust being blown off site.

Objectives

The objectives are the key aims or goals of the control measures that will be out in place to eliminate or minimise, as far as reasonably practicable, the identified risk events.

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each objective does not need to relate to all of the control measures.]

The key objectives of this risk treatment plan are to:

- Reduce or prevent dust generation from onsite activities and materials transport, to the extent practicable.
- Minimise offsite dust impacts on nearby sensitive receptors, including members of the public, residential land uses, and other sensitive land uses or environments.
- Protect the beneficial uses of the air environment as defined in the SEPP (AQM).

Compliance standards

The compliance standards are the key best practice standards or guidelines that will be achieved with the control measures in place. These best practice standards or guidelines may come from the EPA, State Environment Protection Policy or other regulatory agencies.

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each compliance standard does not need to relate to all of the control measures.]

The compliance standards for this risk treatment plan are:

- EPA Protocol for Environmental Management – Mining and Extractive Industries.
- State Environment Protection Policy Air Quality Management (SEPP AQM).
- EPA Guideline: Recommended separation distances for industrial residual air emissions.

Acceptance criteria

The acceptance criteria are the measures by which the control measures will be deemed to be effective in achieving the objective and eliminating or minimising, as far as reasonably practicable, the identified risk events. The acceptance criteria could be to achieve a best practice standard (e.g. an EPA standard).

[Examples are included in the guidance sheets for managing hazards.]

[Note: Each acceptance criteria does not need to relate to all of the control measures.]

The acceptance criteria for this risk treatment plan are:

- No nuisance dust issues experienced by pre-existing, nearby sensitive receptors.
- Dust and particulate emissions do not exceed applicable EPA standards.

Controls to address hazard

The control measures are to be designed to eliminate or minimise, as far as reasonably practicable, the identified risk events. The numbers of the risk events being managed by each control should be recorded against the control along with how the control will be implemented.

[Examples are included in the guidance sheets for managing hazards.]

The controls for this risk treatment plan are:

#	Details of controls being used	Risk events being managed (number from above)	Performance standards/measures *(specifying how the control is being implemented – if not implicit in the control)*
1	Maintain separation between the activity boundary and the property or activity boundary of the nearest sensitive land uses as per EPA Publication 1518 – of 250 m or 500 m.	1, 2, 3	Ensure 250 m buffer retained between operational areas and sensitive receptors.
2	Enclose dust generating equipment (e.g. crushers, conveyors) or fit them with suppression devices to minimise dust emissions. Maintain enclosures or suppression devices to ensure they are operating effectively.	1	Dust suppression devices fitted to all operating dust-generating plant. High level of plant enclosure.
3	Stop dust generating activities (e.g. crushing) where dust suppression devices are not fitted or not operating correctly during very windy conditions.	1	Dust generating activities not undertaken when wind speeds ≥ 60 km/h.
4	Manage onsite roads located within 250 m of a sensitive receptor to minimise dust generation, for example, by sealing or gravelling the road or use of water, polymer or other chemical dust suppressants. Polymer or chemical suppressants to be subject to relevant environmental contamination controls.	1	Onsite roads <100 m from a sensitive receptor are sealed. Chemical dust suppressants are used on onsite roads between 100 m and 250 m from a sensitive receptor.
5	Stabilise soil and overburden stockpiles (e.g. seeded / roughened / mulched) if they will not be disturbed for an extended period. Water or use other dust suppressant agents to prevent dust generation prior to stabilisation.	2	Soil and overburden stockpiles stabilised if not used for 60 days.
6	Cover vehicles carrying dusty materials (soil, sand, rocks etc.) when transferring material to/from the site or treat with water or other dust suppressant to minimise dust generation.	1	Ensure all vehicles have loads covered when exiting site to transfer materials.
7	Install and use wheel wash and/or rumble grids for use by trucks at their main exit points.	1	Wheel wash / rumble grids installed at all site exits.
8	Limit vehicle movements on unsealed or untreated roads/areas to avoid dust generation during windy conditions.	1	Vehicle movements limited to sealed/ watered roads under windy conditions (≥50 km/h)
9	Establish, signpost and enforce speed limits to minimise dust generation from vehicles on roads that are prone to dust generation.	1	Set a 30 km/h speed limit on unsealed roads.

[Add or delete rows from the above table as appropriate]

Residual risk assessment

Considering the controls being put in place the assessment of the residual risk associated with the risk events identified for this hazard is shown in the table below.

[The likelihood and consequence should be assessed using the descriptors provided by Earth Resources Regulation and the risk rating determined using Earth Resources Regulation's risk matrix.]

#	Details of the Risk Event	Phase	Consequence	Likelihood	Residual Risk Rating
1	Generation of dust from plant and equipment	• Construction • Operation • Rehabilitation	Moderate	Possible	Medium
2	Generation of dust from overburden dumps and stockpiles	• Construction • Rehabilitation	Moderate	Possible	Medium
3	Generation of dust from imported fill material	• Operation	Moderate	Possible	Medium

[Add or delete rows from the table below as appropriate]

Monitoring

[List the monitoring of the status or effectiveness of the controls associated with this hazard. Include the aspect being monitored and the detail of the monitoring. Monitoring includes management systems, practices and procedures that are to be applied to monitor and manage risks and compliance with performance standards.]

#	Aspect to be monitored	Details of monitoring
1	Dust deposition at nearest sensitive residential locations	Monitor continuously for 3 months following dust complaint, following applicable EPA guidance.
2	Excessive visible dust being generated on site	Visual observation during windy conditions

[Add or delete rows from the table below as appropriate]

Reporting

[List the reporting of the monitoring, effectiveness or status of the controls associated with this hazard. Include to whom the reporting will be provided, the frequency of the reporting and how it will be used.]

#	Aspect being reported	Who will the information be reported to and at what frequency?	How will it be used?
1	Dust deposition at nearest sensitive residential locations	Report to Community Reference Group quarterly	Use data to confirm presence of dust issue and identify and manage key dust generation activities
2	Excessive visible dust being generated on site	Site management as requested	To manage dust generation activities

[Add or delete rows from the table below as appropriate]

C4 Example controls

Dust

Scope

Guidance to assist applicants to prepare a risk treatment plan for the control of emissions of hazardous and/or nuisance dust or other particulates, particularly beyond the boundary of the licence area.

Key sensitive receptors

Example controls primarily address risks posed to members of the public and residential land uses. Some types of agricultural land use (e.g. wine grapes) and environmental features (e.g. protected flora) may also be highly sensitive to dust.

Objectives

- Reduce or prevent dust generation from onsite activities and materials transport, to the extent practicable
- Minimise offsite dust impacts on nearby sensitive receptors, including members of the public, residential land uses, and other sensitive land uses or environments
- Protect the beneficial uses of the air environment as defined in the SEPP (AQM).

Compliance standards

- EPA Protocol for Environmental Management – Mining and Extractive Industries
- State Environment Protection Policy Air Quality Management (SEPP AQM)
- EPA Guideline: Recommended separation distances for industrial residual air emissions.

Acceptance criteria

- No nuisance dust issues experienced by pre-existing, nearby sensitive receptors
- Dust and particulate emissions do not exceed applicable EPA standards.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. The performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Maintain separation between the dust source and the property or activity boundary of the nearest sensitive land uses as per EPA Publication 1518 – of 250 m or 500 m.	*e.g. Ensure x m buffer retained between operational areas and sensitive receptors.*
2	Enclose dust generating equipment (e.g. crushers, conveyors) or fit them with suppression devices to minimise dust emissions. Maintain enclosures or suppression devices to ensure they are operating effectively.	*e.g. Dust suppression devices fitted to all operating dust-generating plant.* *A high level of plant enclosure.*
3	Stop dust generating activities (e.g. crushing) where dust suppression devices are not fitted or not operating correctly during very windy conditions.	*e.g. Dust generating activities not undertaken when wind speeds ≥ x km/h.*
4	Manage onsite roads located within 250 m of a sensitive receptor to minimise dust generation, for example, by sealing or gravelling the road or use of water, polymer or other chemical dust suppressants. Polymer or chemical suppressants to be subject to relevant environmental contamination controls.	*e.g. Onsite roads <x m from a sensitive receptor are sealed. Chemical dust suppressants are used on onsite roads between x m and y m from a sensitive receptor.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
5	Stabilise soil and overburden stockpiles (e.g. seeded / roughened / mulched) if they will not be disturbed for an extended period. Water or use other dust suppressant agents to prevent dust generation prior to stabilisation.	*e.g. Soil and overburden stockpiles stabilised if not used for x days.*
6	Cover vehicles carrying dusty materials (soil, sand, rocks etc.) when transferring material to/ from the site or treat with water or other dust suppressant to minimise dust generation.	*e.g. Ensure all vehicles have loads covered when exiting site to transfer materials.*
7	Install and use wheel wash and/or rumble grids for use by trucks at their main exit points.	*e.g. Wheel wash / rumble grids installed at all site exits.*
8	Limit vehicle movements on unsealed or untreated roads/areas to avoid dust generation during windy conditions.	*e.g. Vehicle movements limited to sealed/watered roads under windy conditions (≥30 km/h).*
9	Establish, signpost and enforce speed limits to minimise dust generation from vehicles on roads that are prone to dust generation.	*e.g. Set a x km/h speed limit on unsealed roads.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Dust deposition at nearest sensitive residential locations*	*e.g. Monitor continuously for 3 months following dust complaint, following applicable EPA guidance.*
2	*e.g. Excessive visible dust being generated on site.*	*e.g. visual observation during windy conditions*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Dust deposition at nearest sensitive residential locations.*	*e.g. Report to Community Reference Group quarterly.*	*e.g. Use data to confirm presence of dust issue and identify and manage key dust generation activities.*
2	*e.g. Excessive visible dust being generated on site.*	*e.g. Site management as requested.*	*e.g. To manage dust generation activities.*

Dust, silt and clay on roads

Scope

Guidance to assist applicants to prepare a risk treatment plan for the control of risks associated with the carriage and deposition of dust, silt and clay (mud) by vehicles exiting the licence area.

Key sensitive receptors

Example controls primarily address risks posed to members of the public, particularly those using or residing near roads used by traffic exiting the mining operation.

Objectives

- Avoid carriage of dust, silt and clay (mud) by vehicles leaving the licence area.
- Prevent road safety issues from hazards associated with the deposition of dust, silt and clay (mud) onto external roads by traffic from the licence area.

Compliance standards

- *Planning and Environment Act 1979.*
- Planning permit

Acceptance criteria

- Minimise dust, silt and clay (mud) carried by vehicles beyond the boundary of the licence area.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. The performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Install and use wheel wash and/or rumble grids for use by trucks at their main exit points.	*e.g. Vehicle wash or rumble grids installed at the main site exits.*
2	Paving or sealing access roads leaving wheel wash or rumble grids.	*e.g. Paving or sealing installed and maintained.*

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Mud deposition on surrounding roads.*	*e.g. Daily observation.*
2	*e.g. Visible dust emissions on roads.*	*e.g. Daily observation.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Mud deposition on surrounding roads.*	*e.g. Weekly internal reporting increased to daily during wet weather.*	*e.g. Adaptive management during wet weather.*
2	*e.g. Visible dust emissions on roads.*	*e.g. Community Stakeholder Group six monthly.*	*e.g. To assess improvement or maintenance requirements.*

Erosion and sedimentation

Scope

Guidance to assist applicants to prepare a risk treatment plan for the control of erosion and subsequent deposition of sediments. Erosion may take place from stockpiles, constructed embankments, natural slopes and rehabilitated landforms. Sediment deposition may affect the licence area or neighbouring lands and waterways.

Key sensitive receptors

Example controls primarily address risks posed to on and off site environmental features, particularly soils and waterways; as well as water and its beneficial consumptive and environmental uses.

Objectives

- Prevent erosion and sediment runoff from onsite activities.
- Minimise offsite impacts of erosion and sediment run-off on the surrounding environment.
- Protect the beneficial uses of water environments as defined in the SEPP (Waters)
- Minimise the risk of failure of on-site infrastructure (e.g. tailings or slime storages, water storages etc.) due to erosion.

Compliance standards

- State Environment Protection Policy (Waters) (SEPP Waters);
- EPA Guideline 1287 Risk Assessment of Wastewater Discharge to Waterways.
- *Water Act (1989).*
- *Catchment and Land Protection Act (1994).*

Acceptance criteria

- No delivery of sediment to land or waterways outside the licence area beyond what is permitted by the applicable SEPP, water discharge licence and/or appropriate water quality guidelines.
- No unmanaged areas of active soil erosion within the licence area or adjacent areas from site discharges.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. The performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Plan and stage vegetation clearing and earthworks to limit, to the extent practicable given operational requirements, the total surface area of land exposed at one time.	*e.g. < x ha of land disturbed at one time.*
2	Install interception drains upstream and downstream of areas of disturbed ground, including stockpiles and unsealed roads, to minimise surface water flow onto such areas. Contain water carrying sediments from roads or other disturbed areas for suitable treatment.	*e.g. Interception drains constructed and operating effectively.*
3	Design, size and maintain sediment control ponds or other structures to retain water until all sediment from the design storm event has fallen out of suspension.	*e.g. Temporary structures will be designed to accommodate a 1 in x year storm event of y hours. Permanent structures will provide for a 1 in z year storm.* *Compliance with the SEPP suspended particles requirements.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
4	Locate soil and overburden stockpiles away from waterways to minimise the risk of sediment discharge to waterways.	*e.g. Stockpiles located ≥ x m from any waterway.*
5	Stabilise soil and overburden stockpiles (e.g. seeded / roughened / mulched) and other disturbed areas as soon as practicable.	*e.g. Soil and overburden stockpiles and other disturbed areas stabilised if not used for 28 days.*
6	Maintain the angle and height of exposed working faces and/or stockpiles to minimise erosion and sediment generation to the extent practicable.	*e.g. Clay: slope of < x:y (V:H)* *Sand: slope of < x:y (V:H)*
7	Install effective velocity check and/or silt control structures in drainage lines to minimise scouring and sediment generation.	*e.g. Sandbag: drain < x mm deep and ≤ y% slope.* *Rock dam: drain > x mm deep and ≤ y% slope.* *Silt curtains installed.*
8	Plan and construct the final landform to minimise erosion and sediment run-off.	*e.g. Slopes graded to < x:y (V:H).* *Stabilisation measures applied (e.g. mulch, seedlings, geotextiles, etc).*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Effectiveness of sediment control structures.*	*e.g. Condition and operating effectiveness pre-winter and following each major rainfall effectiveness.*
2	*e.g. Compliance with the EPA standard and/or requirements of a discharge licence .*	*e.g. As required by SEPP or discharge licence.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Effectiveness of sediment control structures.*	*e.g. Quarterly report to the Community Reference Group.*	*e.g. Use data to plan maintenance of drainage sediment control features.*
2	*e.g. Compliance with the EPA standard and/or requirements of a discharge licence.*	*e.g. Site management or EPA as required.*	*e.g. To ensure compliance with SEPP or discharge licence requirements.*

Fire

Scope

Guidance to assist applicants to prepare a risk treatment plan to mitigate risks from bushfires burning onto the licence area and from fires igniting on-site and escaping to surrounding areas.

Key sensitive receptors

Example controls address risks posed to members of the public, land and property and the environment.

Objectives

- Control potential sources of fire ignition and activities that could lead to fire ignition and escape on days of elevated fire danger.
- Minimise environmental and human safety risks associated with fires burning onto a licence area.

Compliance standards

- *County Fire Authority Act (1958)*
- Country Fire Authority Regulations (2015)
- *Planning and Environment Act (1987)*
- Code of Practice for Bushfire Management on Public Land (2012).

Acceptance criteria

- Any fire ignitions originating within the licence area are contained within it.
- Grass or bushfires burning onto the licence area do not cause health or safety incidents and result in minimal environmental harm.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	For sites located on bushfire prone land, develop and implement "hot work" procedures for the conduct of activities in the open that are a potential source of fire ignition.	*e.g. Written hot work procedures have been developed.*
2	No "hot work" to be undertaken in the open air on days of Total Fire Ban without a permit from the CFA.	*e.g. No ignition sources used on Total Fire ban days.*
3	Provide fire-fighting equipment in all on-site vehicles and mobile plant and maintain the equipment in good working order.	*e.g. Fire-fighting equipment in all vehicles and maintained as per the maintenance schedule.*
4	Relevant personnel working on sites in bushfire prone areas will be provided with information and training regarding the fire hazard conditions in the area, "hot work" procedures, relevant emergency response procedures and use of applicable equipment.	*e.g. x % of relevant personnel trained within Y month of commencement.*
5	Internal-combustion engines will be fitted with exhaust pipes, mufflers and spark arresters (where consistent with manufacturers specifications) and maintained in good working order.	*e.g. Where consistent with manufacturers specifications engines are fitted with spark arresting devices.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
6	Provide fire-fighting equipment in all site buildings and maintain it in good working order. Equip water carts with pressure pumps and fire fighting hose.	*e.g. Fire-fighting equipment in all site buildings.*
7	Flammable and combustible wastes are removed from the site as soon as practicable.	*e.g. No flammable waste is stockpiled onsite.*
8	For sites located on bushfire prone land, check the National Fire Danger Rating for the area of the site each work day during the prescribed fire danger period. Communicate the hazard rating and any specific instructions to site personnel.	*e.g. Fire Danger Rating checked daily and communicated to site personnel.*
9	Establish and maintain fire breaks around site boundaries in high risk fire areas.	*e.g. Fire breaks installed and maintained. Audit before high risk season.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Hot work approvals.*	*e.g. Establish and maintain a register of hot work approvals and hot works undertaken.*
2	*e.g. Training of personnel in high fire risk area.*	*e.g. Numbers of staff trained.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Hot work approvals.*	*e.g. Monthly internal reporting and safety compliance assurance.*	*e.g. To ensure risks are being managed.*
2	*e.g. Training of personnel in high fire risk area.*	*e.g. Site management annually prior to fire season.*	*e.g. Availability of trained personnel to assist in fire emergency.*

Fuel, lubricants and hazardous materials

Scope

Guidance to assist applicants to prepare a risk treatment plan to manage risks associated with the storage, use and handling of fuel, lubricants and hazardous materials to minimise risks to the environment.

Key sensitive receptors

Example controls primarily address risks posed to the environment.

Objectives

- Minimise the risk of fuels, lubricants and hazardous materials released into the environment through leaks, spills and through stormwater runoff.

Compliance standards

- State Environment Protection Policy (Waters). [SEPP Waters]
- State Environment Protection Policy (Prevention and Management of Contaminated Land). [SEPP Contam Land]
- Environment Protection (Scheduled Premises & Exemptions) Regulation (2007)
- Environment Protection (Industrial Waste Resource) Regulations (2009)
- AS1940 – Storage and Handling of Flammable and Combustible Liquids.

Acceptance criteria

- Fuels, lubricants and hazardous materials are stored in accordance with AS 1940
- Compliance with relevant SEPPs.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Design and install bunding and surface sealing of storage area sufficient to hold 125% of the total volume of the hazardous material.	*e.g. Bund height, volume of the bunded area in relation to the amount of substances stored, imperviousness of the bunded area i.e. Impervious material used for lining.*
2	Locate the storage are away from the waterways or areas prone to flooding.	*e.g. Buffer distance between the storage area and the sensitive receptors.*
3	Minimise the amount of fuels, lubricants and hazardous materials stored on site by limiting the volume of hazardous substances stored onsite to the minimum required for the activity.	*e.g. Register established and maintained* *Not more than x L of fuel or hazardous material stored onsite.*
4	Provide spill and leakage protection around areas where fuels, lubricants and hazardous substances are stored and handled. Controls may include: • locating activities on compacted sealed ground; • use of drip trays; • installation of oil/water interceptors in drainage lines; • sedimentation filters / ponds in drainage lines; • construction of earthen bunds etc.	*e.g. All areas protected against spills and leaks.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
5	Underground tanks / sumps for the storage of hazardous substances (such as fuel, waste oils, effluent) are not installed at the site.	*e.g. No underground storage structures are present.*
6	Inspect and maintain spill control equipment.	*e.g. Daily visual inspection and inspection records maintained.*
7	Ensure appropriate clean-up equipment and materials are available.	*e.g. Equipment and materials are available and accessible to all the sites and all the time.*
8	Notify relevant authorities of significant spills or leaks.	*Record of all spill reports maintained.*
9	Ensure drainage from areas where spills may occur is diverted through a sump or interceptor.	*e.g. Sumps/interceptors of adequate capacity are in place.*
10	Manage water and stormwater runoff in and surrounding site to reduce the potential for impacts on environment.	*e.g. Construction and maintenance of onsite drainage.*
11	Provision of fire control equipment and maintained in areas where flammable / combustible hazardous substances are stored.	*e.g. Records of regular maintenance.*

[Note: Values in the performance measure examples are intended to be defined for the site, but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Volume of fuels, lubricants and hazardous materials available at the site.*	*e.g. Regular periodic stocktake (e.g. monthly).*
2	*e.g. Pollution control devices maintained and serviced.*	*e.g. Six monthly audit.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Volume of fuels, lubricants and hazardous materials available at the site.*	*e.g. Register established and maintained, monthly internal reporting.*	*e.g. To determine when higher volumes are being stored on site and further precautions are to be taken.*
2	*e.g. Pollution control devices maintained and serviced.*	*e.g. Results of six monthly audits.*	*e.g. Plan maintenance upgrades as required.*

Imported materials

Scope

Guidance to assist applicants to prepare a risk treatment plan to manage risks associated with the import, storage and/or management of hazardous or non-hazardous solid materials to the licence area.

Key sensitive receptors

Example controls primarily address risks posed to the environment, particularly soils, waterways and related terrestrial and aquatic ecosystems.

Objectives

- Prevent contamination of the site by importing hazardous materials or soils carrying seeds of declared weeds or infested with soil-borne plant diseases.
- Prevent unlicensed importation and storage of domestic or industrial wastes and hazardous materials.

Compliance standards

- *Environment Protection Act (1970)*
- *Catchment and Land Protection Act (1994)*
- *Planning and Environment Act (1979)*
- *Mineral Resources (Sustainable Development) Act (1990)*
- State Environment Protection Policy (Waters) (SEPP Waters)
- Earth Resources Regulation Imported Materials Management Guidelines for Mine and Quarry Operations.
- EPA Publication No. IWRG621 Industrial Waste Resource Guidelines – Soil hazard categorisation and management.
- EPA Publication No. IWRG631 Industrial Waste Resource Guidelines – Solid industrial waste hazard categorisation and management.
- EPA Publication No. IWRG600.2 Industrial Waste Resource Guidelines – Waste Categorisation.
- EPA Publication No. 655.1 Acid Sulfate Soil and Rock.

Acceptance criteria

- The management of imported materials does not detract from beneficial uses of soil, surface water or groundwater within or near the licence area.
- Importation and management of imported materials fully complies with applicable legislative and regulatory requirements.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Obtain any required approvals for the import of materials from local government (via a planning permit) and/or ERR (via a work plan or work plan variation) prior to the commencement of importation of materials.	*e.g. All permits and approvals in place before commencement.*
2	Obtain certification from supplier that imported material meet the requirements for clean fill as defined in the Industrial Waste Resource Regulations (IWRG). Spot check loads to confirm their composition is consistent with their classification.	*e.g. Imported materials meets criteria for clean fill and has appropriate certificates.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
3	Prohibit the import of domestic waste, prescribed industrial wastes and acid sulfate soils or other acid-forming rocks to the site.	*e.g. No domestic or prescribed waste imported to the Licence area.*
4	Weigh and visually inspect each load of material imported to site and record tonnage and source. Segregate materials imported from different sources until they are confirmed as clean and suitable for use.	*e.g. Materials receipt records are maintained.* *Imported materials are segregated until confirmation of their suitability for use within the Licence area.*
5	Only import soil from sites that are known to be free of pathogens and declared weeds (and their seeds). Maintain a register of this information for any soil, fill or similar material imported onto the licence area.	*e.g. Imported soil is verified as weed and pathogen free.*

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Composition of loads of imported materials.*	*e.g. Inspect to confirm material composition is consistent with clean fill definition.*
2	*e.g. Obtain relevant certificates for imported materials.*	*e.g. Maintain a register of certificates for imported material.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Composition of loads of imported materials.*	*e.g. Monthly internal recording and annual external reporting of compliance with licence conditions.*	*e.g. To ensure compliance with licence conditions.*
2	*e.g. Obtain relevant certificates for imported materials.*	*e.g. Community Stakeholder Group every six months.*	*e.g. Provide assurance that no waste or hazardous materials are being deposited on site.*

Noise

Scope

Guidance to assist applicants to prepare a risk treatment plan for the control of noise, particularly as it has potential to affect sensitive receptors beyond the boundary of the licence area.

Key sensitive receptors

Example controls primarily address risks posed to members of the public and residential land uses. Some types of agricultural land use (e.g. horses) and environmental features (e.g. migratory bird breeding areas) may also be highly sensitive to noise.

Objectives

- Reduce noise generation from onsite activities and materials handling to the extent practicable.
- Minimise offsite noise impacts on nearby sensitive receptors, including members of the public, residential land uses and other sensitive land uses or environments.
- Protect the beneficial uses of the air environment as defined in the SEPP N-1.
- Noise experienced by nearby sensitive receptors is within specifications of SEPP N-1 or NIRV guideline.

Compliance standards

- EPA Guideline 1411 – Noise from Industry in Regional Victoria (NIRV).
- State Environment Protection Policy (Control of Noise from Commerce, Industry and Trade) (SEPP N-1).

Acceptance criteria

- Noises levels at nearby sensitive receptors do not exceed applicable EPA standards.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	**Performance measures** (specifying how the control is being implemented – examples shown below)
1	Locate noise generating plant and equipment away from noise sensitive receptors.	*e.g. Minimum x m buffer distance maintained between operational areas and noise sensitive receptors.*
2	Plan the site layout to screen operational areas from noise sensitive receptors. Where possible: • Locate site access roads away from sensitive receptors; • Use existing features (i.e. topography, vegetation) and/or stockpiles or other constructed features as noise barriers; • Locate noisy equipment away from sensitive receptors; Maintain the minimum buffer / set-back distances specified in the planning permit.	*e.g. Locations with noise generating activities effectively screened from noise sensitive receptors.* *Install vegetated bund walls where required.*
3	To the extent practicable, specify low noise generating equipment when selecting equipment for on-site use.	*e.g. As far as practical all equipment used on site will have a low noise rating.*
4	Maintain (active) site roads in good condition to minimise noise from vehicle traffic over corrugations and pot holes.	*e.g. Corrugations and potholes are remedied as soon as possible to minimise their presence.* *Implement maintenance grading plan.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
5	Where practicable and consistent with manufacturer's specifications, fit (or retain) mobile noise-generating equipment, pneumatic equipment and/ fixed internal combustion engines with noise attenuation devices (e.g. enclosures, baffles, silencers, mufflers etc.) and maintain equipment in good repair.	*e.g. Noise abatement devices fitted to all operational noise generating plant.*
6	Limit materials haulage from the licence area to licenced operating hours and minimise excessive noise levels from dusk to dawn, e.g. drilling.	*e.g. Licenced operating hours:* • *X am – Y pm Mon to Fri.* • *X am till Z pm on Sat.* • *No work on Sun or public holidays.*
7	Turn off plant, equipment and vehicles when not in use for an extended period.	*e.g. No plant, equipment or vehicles remain on when not in use.*
8	Broadcast or loudspeaker system, telephone ringer or other external alarm are not routinely used (except as a warning alarm e.g. for blasting).	*e.g. No external broadcast systems are used.*
9	Fit low frequency reversing noise signals to all applicable mobile plant.	*e.g. All applicable mobile fitted with low frequency reversing noise signals.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Noise at nearest sensitive residential locations comply with the SEPP requirements.*	*e.g. Monitor regularly for 3 months following noise complaint*
2	*e.g. After hours noise levels (dusk to dawn)*	*Assess all after hours noise sources.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Noise at nearest sensitive residential locations.*	*e.g. Monthly Internal reporting for management following a complaint.*	*e.g. Use data to confirm presence of noise issue and identify and manage key noise generation activities.*
2	*e.g. After hours noise levels (dusk to dawn).*	*e.g. Site management as required.*	*e.g. To reduce after hours noise emissions.*

Pests, weeds and diseases

Scope

Guidance to assist applicants to prepare a risk treatment plan to control and avoid introducing weeds, pest animals and/or soil-borne disease to the site of a mine and threatening biodiversity and/or agricultural production values associated with the site and surrounding areas.

Key sensitive receptors

Example controls primarily address risks posed to the environment and primary production land uses.

Objectives

- Protect biodiversity values associated with the licence area.
- Prevent site activities contributing to the proliferation of noxious weeds, plant diseases or pest animals, on or off the licence area

Compliance standards

- *Catchment and Land Protection Act (1994)*
- *Planning and Environment Act (1987)*
- *Public Health and Wellbeing Act (2008)*
- *Agricultural and Veterinary Chemicals (Control of Use) Act (1992)*
- Agricultural and Veterinary Chemicals (Control of Use) Regulations (2007).

Acceptance criteria

- Site operator complies with legislative requirements relating to the control and management of declared noxious weeds and pest animals.
- The mining or extractives operation does not contribute to the spread or proliferation of soil-borne plant diseases.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	**Performance measures** (specifying how the control is being implemented – examples shown below)
1	Eradicate or manage any declared noxious weeds or established pest animals present on the Licence area.	*e.g. Infestations of declared noxious weeds and established pest animals are eradicated or controlled.*
2	Identify pest species habitats within the licence boundary and remove refuge areas (burrows, hollow logs) where practicable and consistent with native vegetation protection requirements.	*e.g. Pest animal habitats are removed or destroyed.*
3	Any soil imported to the site is to be from a location that is known to be free of pathogens, disease and noxious weeds (and their seeds).	*e.g. Imported soil is verified as weed and pathogen free.*
4	Disinfect equipment moved from areas known or suspected to contain Phytophthora cinnamomi. Disinfection is to be carried so that water or other materials from disinfection cannot reach a waterway or contaminate native vegetation habitats.	*e.g. Hygiene procedures are in place and followed in areas with known or suspected Phytophthora cinnamomi presence.*
5	Identify and map areas within the licence boundary that contain declared noxious weeds (under the CaLP Act) and establish exclusion zones until the weeds are controlled and/or the area is fully disturbed by the activity.	*e.g. Areas containing declared weed species are not disturbed by site activities.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
6	Limit vegetation clearing and surface disturbance activities to the minimum required operationally.	*e.g. Limit clearing to ≤ x m in advance of operational areas.*
7	Engage appropriately licenced personnel to conduct any required pesticide application to control weeds and/or pest animals.	*e.g. Only licensed personnel are permitted to apply pesticides.*
8	Stockpile and manage soils from areas with noxious weed infestations separately to other soils to avoid cross contamination.	
9	Vermin management mitigated by the removal of waste, rubbish, etc. by licensed contractor.	*e.g. Regular waste and rubbish collection services in place.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Site flora and fauna for noxious weeds and pests.*	*e.g. Inspect all areas to assess the health of the vegetation and to check for erosion, pest animal browsing damage and weed infestation.*
2		

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Site flora and fauna for noxious weeds and pests.*	*e.g. Monthly internal reporting for management.*	*e.g. For management intervention if rehabilitation areas have emerging weed or pest animal issues.*
2			

Rubbish

Scope

Guidance to assist applicants to prepare a risk treatment plan to manage risks to the environment from the storage and/or management of rubbish or industrial wastes (as defined by EPA) within a licence area. These controls do not apply to prescribed industrial wastes, acid-forming rocks or acid sulphate soils.

Key sensitive receptors

Example controls primarily address risks posed to the environment, but also address amenity for members of the public and nearby residents.

Objectives

- Prevent rubbish and industrial wastes generated by site activities from adversely affecting soil, water or other aspects of the environment.
- Protect the beneficial uses of water and soil environment as defined in relevant State Environment Protection Policies (SEPPs).

Compliance standards

- SEPP (Waters)
- SEPP (Prevention and Management of Contaminated Land)
- Environment Protection (Scheduled Premises & Exemptions) Regulation (2007)
- Environment Protection (Industrial Waste Resource) Regulations (2009).

Acceptance criteria

- Beneficial uses of soil, water and air within and near the licence area are not detrimentally affected by the storage and/or management of rubbish or industrial wastes.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Segregate wastes generated on-site (by type and hazard) for recycling or disposal. Recover and reuse site generated wastes where possible (e.g. mulching of green waste for use in rehabilitation).	*e.g. Waste is segregated at source and is re-used on-site where practicable.*
2	No on-site disposal (or burning) of rubbish and/or prescribed wastes generated from site activities. Use appropriately licenced off-site services / facilities to recycle or dispose of site generated wastes.	*e.g. No domestic or prescribed industrial wastes disposed on-site.*
3	Assess all rubbish and industrial wastes for potential for contamination and manage/ dispose in accordance with EPA requirements.	*e.g. Licensed contractors are used for the disposal of all rubbish and waste material.*
4	Limit the volume and permitted timeframe for wastes to be stored onsite.	*e.g. Waste materials not held on-site for more than x month.*
5	Protect waste storage areas from rainfall and stormwater or flood ingress.	*e.g. Covered waste storage areas and/or bins.*
6	Locate waste storage away from areas of protected habitat and/or waterways.	*e.g. x m buffer distance maintained between waste storage areas and protected habitat and/or waterways.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
7	Develop and implement appropriate training on waste management measures to limit the generation and accumulation of waste on site.	
8	Provide covered bins for temporary on-site storage of rubbish and domestic wastes.	*e.g. Sealed bins provided.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Wastes stored on site.*	*e.g. Quantities, types and location of prescribed wastes stored on site.*
2	*e.g. Approved disposal of wastes.*	*e.g. Register of licensed contractors.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Wastes stored on site.*	*e.g. Monthly internal reporting and safety compliance assurance.*	*e.g. Use in case of fire or other emergency.*
2	*e.g. Approved disposal of wastes.*	*e.g. Regulatory authorities six monthly or as required.*	*e.g. Compliance with SEPP or regulations.*

Site access

Scope

Guidance to assist applicants to prepare a risk treatment plan for unauthorised access to the licence area by members of the public and to provide for safe authorised access.

Key sensitive receptors

Example controls primarily address risks posed to members of the public.

Objectives

- Provide for the safety of members of the public when accessing a licence area.
- Prevent unauthorised access to the licence area by members of the public.

Compliance standards

- Mineral Resources (Sustainable Development) (Mineral Industries) Regulations 2019
- *Safety on Public Land Act (2004)*
- Licence conditions.

Acceptance criteria

- Boundary of licence area is appropriately marked and secured
- Operating area for mine is secured to minimise chances of unauthorised entry.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Identify, mark and fence the boundary of the licence area in compliance with the MRSD (Mineral Industries) Regulations 2019.	*e.g. The site boundary is identified with compliant boundary markers and fully fenced with lockable access gates.*
2	Lock all gates when site is unattended. Control access to site when site is attended.	*e.g. Site gates locked or otherwise secured.*
3	Design and construct onsite roads to safely accommodate the size and type of vehicles accessing and travelling within the site. Separate any general traffic from any internal haul routes.	*e.g. For one-way traffic, the track should be twice the width of the widest vehicle. For two-way traffic, the track should be three times the width of the widest vehicle.*
4	Install site access safety signage around boundary fence and at all access points.	*e.g. Hazard warnings against unauthorised access.*

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Site entry by members of the public.*	*e.g. Register of all visitors to site.*
2	*e.g. Site security breaches (unauthorised access).*	*e.g. Records kept of site security breaches.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Site entry by members of the public.*	*e.g. Daily internal reporting.*	*e.g. Ensure all visitors have exited site prior to end of operating hours.*
2	*e.g. Site security breaches (unauthorised access).*	*e.g. Reported to site management and regulatory authority as required or six monthly.*	*e.g. Improve site security to limit unauthorised site access.*

Soil biological activity

Scope

Guidance to assist applicants to prepare a risk treatment plan to help maintain the biological activity of undisturbed and stockpiled soils within the licence area. It does not address the storage of contaminated soils or potential acid sulphate soils.

Key sensitive receptors

Example controls primarily address risks posed to on-site soils and the successful rehabilitation of the mine site.

Objectives

- Protect existing soil structure, nutrient levels and biological activity in onsite soils
- Facilitate the rehabilitation of the mine site by maintaining biological activity in stockpiled soils.

Compliance standards

- *Catchment and Land Protection Act (1994).*

Acceptance criteria

- The health of biologically active soil is maintained while it is stockpiled and reused in rehabilitation.

Example Controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Install and use wheel wash and/or rumble grids for use by trucks at their main exit points.	*e.g. Wheel wash and/or rumble grids are installed for use by trucks at their main exit points.*
2	As applicable to the site, segregate each soil layer / type into individual stockpiles for future reuse. This must include surface organic matter and larger woody debris.	*e.g. Individual soil strata (topsoil, overburden, gravel, humus etc) are retained in separate stockpiles.*
3	If possible do not strip soil when it is very dry or saturated.	*e.g. Condition of soil stockpile maintained.*
4	Maintain soil stockpiles at no more than 2 m height.	*e.g. Stockpiles ≤ x m height.*
5	Replace stockpiled soil strata (during rehabilitation) in their original order to maintain the natural soil profile.	*e.g. The soil's original profile is restored during rehabilitation.*
6	Stabilise soil and overburden stockpiles (e.g. seeded / roughened / mulched) if they will not be disturbed for an extended period.	*e.g. Soil and overburden stockpiles are stabilised if not used for x days.*
7	Any soil imported to site must be from a location that is known to be free of pathogens, disease and noxious weeds (and their seeds).	*e.g. Imported soil is verified as weed and pathogen free.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Maintenance of site soil stockpiles.*	*e.g. Quality of stockpile maintained for future reuse on site.*
2	*e.g. Soils imported to the site.*	*e.g. Register of point of origin, location of storage and confirmation of the weed and disease free status of the origin.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Maintenance of site soil stockpiles.*	*e.g. Site management environmental officer on a six monthly basis.*	*e.g. Quality of stockpile maintained for future reuse on site.*
2	*e.g. Soils imported to the site.*	*e.g. Monthly internal reporting.*	*e.g. Trace soils if disease or weed outbreak occurs.*

Stormwater

Scope

Guidance to assist applicants to prepare a risk treatment plan to manage risks associated with the stormwater generated within the site to minimise its impacts on environment and infrastructure.

Key sensitive receptors

Example controls primarily address risks posed to environment, particularly waterways and related ecosystems from the stormwater runoff and the site infrastructure such as roads.

Objectives

- Protect the beneficial uses of the local water environment as defined in the SEPP (Waters)
- Minimise the impact to the onsite roads and other infrastructure due to stormwater runoff.

Compliance standards

- *Water Act (1989)*
- *Catchment and Land Protection Act (1994)*
- *Planning and Environment Act (1979)*
- State Environment Protection Policy (Waters) (SEPP Waters)
- EPA Guideline 1287 Risk Assessment of Wastewater Discharge to Waterways.

Acceptance criteria

- Stormwater is managed to meet the SEPP
- No nuisance stormwater flooding/inundation of roads and other infrastructure.

Example controls to address hazard

*These controls are **suggestions for consideration** by applicants. Some or all may be used, with or without additional controls. Performance measures should be determined by the applicant to specify how the control is to be implemented, where this is not implicit in the details of the control. Performance measures should include relevant specifics such as buffer distances, vehicle speed, the decibel range or the range of particulate matter as appropriate.*

#	Details of controls being used	**Performance measures** (specifying how the control is being implemented – examples shown below)
1	Construct roads with sufficient diversion drains and culverts to ensure that clean stormwater is diverted away from roads.	*e.g. Survey set out of roads and designs where necessary employ surface treatment to reduce erosion.*
2	Ensure that the gradient and orientation of tracks do not cause runoff to be fast flowing.	*e.g. Maintenance of tracks to minimise erosion.*
3	Arrange drainage of roads to be a vegetated area through erosion protection structures.	*e.g. Side and angled drain off collection drains protected against erosion.*
4	Ensure that drainage from an area where fuels/ lubricants/ hazardous material are stored/used is directed to a sump or an interceptor trap.	

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. storm water culverts and discharge points.*	*e.g. Inspect outlet area to assess the potential for contaminated stormwater to exit the site.*
2	*e.g. Erosion control structures.*	*e.g. Inspect and maintain erosion control structures.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. storm water discharge points.*	*e.g. Monthly internal and external reporting.*	*e.g. Management intervention depending on the severity of the incident. For example, notify DEDJTR as soon as practicable after they become aware of a Reportable Event at the site (as defined in the ERR Guidance Note).*
2	*e.g. Erosion control structures.*	*Site management after significant rainfall event or six monthly.*	*e.g. Upgrade or maintain control structures.*

Water

Scope

Guidance to assist applicants to prepare a risk treatment plan for the management of risks associated with the diversion or disturbance of natural path of flows along waterways or drainage lines. It does not deal with the extraction of water from waterways or groundwater, nor the discharge of process water to the environment.

Key sensitive receptors

Example controls primarily address risks posed to the environment, particularly waterways and related ecosystems.

Objectives

- Prevent site activities from adversely affecting local surface and groundwater sources.
- Protect the beneficial uses of the local water environment as defined in the SEPP (Waters)

Compliance standards

- *Water Act (1989)*
- *Catchment and Land Protection Act (1994)*
- *Planning and Environment Act (1979)*
- State Environment Protection Policy (Waters) (SEPP Waters)
- EPA Guideline 1287 Risk Assessment of Wastewater Discharge to Waterways.

Acceptance criteria

- The diversion and return of diverted water to the environment does not detract from beneficial uses of surface water or groundwater.

Example controls to address hazard

*These controls are **suggestions for consideration** for a mining proponent, some or all may be used, with or without additional controls. Performance measures should be determined by the proponent to specify how the control is to be implemented, where this is not implicit in the details of the control. Where required the performance measure should include the specifics of such things as buffer distances, vehicle speed, the decibel range or the range of particulate matter.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
1	Where reasonably practicable, locate the activity outside of areas designated as a floodplain and/or Land Subject to Inundation.	*e.g. Site located outside designated flood zones.*
2	Install diversion drainage structures up-gradient of working areas to prevent clean surface water from entering the site and becoming contaminated.	*e.g. Surface water diversion structures installed and effectively intercepting surface water before it reaches operating areas.*
3	Construct and maintain diversion structures to limit impacts on downstream / offsite surface water flows. (e.g. alteration of drainage pathways, change in flow), including installing scour protection on the outlet of surface water diversion drains.	*e.g. Downstream environmental flow is maintained.*
4	Design onsite diversion drains to accommodate the surface water flows for a 1 in 10 year storm event (10% AEP), based on the area of the up-gradient catchment area.	*e.g. Diversion drains designed for 1 in 10 year storm event.*

#	Details of controls being used	Performance measures (specifying how the control is being implemented – examples shown below)
5	If diversions of water activities require: • extraction of water from a waterway or existing dam; • construction of a dam on a waterway; Ensure an appropriate 'Take & Use Licence' is obtained from the relevant Rural Water Corporation. A "Works on Waterways" approval must be obtained from a Catchment Management Authority for activities involving works on waterways.	*e.g. Ensure an appropriate 'Take & Use Licence' is obtained from the relevant Rural Water Corporation.* *Ensure A "Works on Waterways" approval is obtained from a Catchment Management Authority for activities involving works on waterways.*

[Note: Values in the performance measure examples are intended to be defined for the site but should take into account any compliance standards or acceptance criteria.]

Monitoring

#	Aspect to be monitored	Details of monitoring
1	*e.g. Condition of waterway at outlet of diversion drain.*	*e.g. Inspect outlet area to assess the potential for erosion and the effectiveness of scour protection features.*
2	*e.g. Effectiveness of upstream diversion drainage structures.*	*e.g. Inspected and maintained as required.*

Reporting

#	Aspect to be reported	Who will the information be reported to and at what frequency?	How will it be used?
1	*e.g. Condition of waterway at outlet of diversion drain.*	*e.g. Internal reporting for site management after significant rainfall event or six monthly.*	*e.g. intervention if erosion issues emerge.*
2	*e.g. Effectiveness of upstream diversion drainage structures.*	*e.g. Internal reporting for site management after significant rainfall event or six monthly.*	*e.g. Assess effectiveness and maintenance requirements.*

Relevant industry publications

Appendix D
Example works for notification

Examples where no variation to a work plan is triggered

a. **Relocation of a haul road**

A mine operator proposes to relocate a haul road within the licence boundary. There is no change to risk based on the location of nearby sensitive receptors. The mine operator notifies Earth Resources Regulation of the change and updates its work plan to note the new location of the haul road. Where a haul road is moved further away from receptors, this relocation would act as a mitigation measure to reduce risk.

b. **Increase in depth of a pit**

There are circumstances where increasing the depth of a pit will not result in a significant increase in risk. Where the batters retain a designated slope and no groundwater is intercepted, it is unlikely a variation would be triggered.

c. **Modification to plant**

A mine operator may wish to upgrade/modify or move the processing plant further away from sensitive receptors as a mitigation measure to control dust, noise or vibrations. These actions would not trigger a work plan variation.

d. **Changes to the staging of the mine**

In some circumstances changing the staging of the development of a mine may not result in a significant increase in risk. Where there are no changes to the rehabilitation plan and any changes to the native vegetation offset plan can be accommodated it is unlikely that a work plan variation would be needed.

e. **Increase in production rate**

A mine operator may wish to increase the processing rate of the mine. If no significant increase in risk to the sensitive receptors can be demonstrated through recent dust and noise modelling and alterations to traffic management are acceptable to Council a work plan variation may not be triggered.

f. **Increase in extraction area for a pit within the existing licence boundary**

A mine operator may wish to increase their pit footprint using the same mining method as detailed in their work plan. Provided there is no significant increase in risk with vegetation clearance or geotechnical risks to infrastructure and council consents to this under the planning permit it may not trigger a work plan variation. An example would be a pit undertaking shallow extraction with flat batters and with no fixed plant involved. Revised drawings will need to be provided to be read in conjunction with the work plan.

E1 Example site meeting agenda

Site:	
Location (address):	
Date:	
Time:	

Attendees:

Organisation	Name	Position title
Applicant		
Consultant		
ERR		
Council		
DELWP		
EPA		
CMA		
AV		
Heritage Vic		
Water Authority		
Other		

Note: the applicant/consultant will record key site meeting outcomes and circulate them to all invitees.

Agenda:

#	Item	Who
1	Welcome and introduction of attendees	Applicant/Consultant/All
2	Roles and responsibilities	Applicant/Consultant/All
3	Proposal overview	Applicant/Consultant
4	Site description • Current use • Geology • Reserves • Sensitive receptors	Applicant/Consultant
5	Current approvals or licences in place	Applicant/Consultant
6	Proposed mining method • Locations of equipment, dumps and dams (slimes/tailings) • Blasting requirements • Batter angles	Applicant/Consultant
7	Proposed rehabilitation and end use	Applicant/Consultant

#	Item	Who
8	Earth Resources Regulation (ERR) comments and requirements • Work plan requirements? • Potential hazards and risks? – Member of the public – Land, property and infrastructure – Environment • Surface water and groundwater? • Other management plans? – Blast management? – Ground control? – Community engagement? – Rehabilitation? • Final land form and end use • Other?	ERR Representative
9	Council comments and requirements • Planning permit requirements? • Road access and traffic management? • Community consultation?	Council Representative
10	Department of Environment, Land, Water and Planning comments (DELWP) and requirements • Planning overlays? • Flora and fauna reports? • *Environment Protection and Biodiversity Conservation Act 1999*?	DELWP Representative
11	Other regulator/agency comments and requirements • EPA • Local Catchment Management Authority • Aboriginal Affairs Victoria • Heritage Victoria – Heritage overlay? • Other?	Agency Representatives
12	Work plan assessment process • Submitting the work plan • Fees • Assessment • Further information • Reassessment • Referral • Endorsement • Planning permit • Approval • Application for work authority & rehabilitation bond • Grant of work authority • Start work	ERR Representative
13	Next steps	Applicant/Consultant

E2 Example site meeting questions

The following questions or issues may be discussed at the initial site meeting. This checklist will help the Tenement holder identify the information to provide in the work plan.

Discussion Topic	Details
Extraction proposal	• What is the estimated life of the activity? • What is the estimated/anticipated volume of resource per annum (output in tonnes or cubic metres)? • What is the estimated volume of soils and overburden to be disturbed? • What are the operating hours?
General location information	• What road(s) are proposed to be used for entering/exiting the activity area? • Are there any known inherited issues as a result of past or current land use?
Blasting	• Will blasting take place? If so, is it possible that blasting related activity could cause vibrations/noise/fly rock at the boundary of (or beyond) the activity area impacting sensitive receptors or infrastructure, including pipelines?
Noise	• Is it likely that activity area-based noise will be heard at any sensitive receptor?
Dust	• Is it likely the operations will generate dust or spray that will be deposited or emitted outside of the activity area boundary? • Is it likely the operations will generate any other substances listed as Class 1, 2 or 3 indicators under Protocol for Environmental Management (2007) that will be emitted outside of the activity area boundary?
Community facility/ private and public infrastructure	• Are there known above and below ground infrastructure (electricity networks, water mains, designated waters etc.) located near the activity area? • Are there known public roads, bridges or train lines located near the activity area?
Aboriginal Heritage	• Are there any areas of cultural heritage sensitivity or other protected areas in the proposed activity area? • Are any caves or dunes identified in the activity area? • Is a CHMP is required?
Historic heritage	• Does the activity area contain places, sites or objects on the: • Heritage overlay of the relevant planning scheme • Victorian Heritage Register • Victorian Heritage Inventory? • Are there historical heritage sites, structures or artefacts that must be retained as part of the post closure land form?
Flora and fauna	• Is any flora or fauna, including native vegetation, within the activity area to be removed or impacted? • Are there weeds, pests or feral animals within the activity area, or from surrounding areas, that could impact rehabilitation activities and/or potential land uses after closure?
Groundwater	• What is the depth to groundwater and water quality objectives as defined in the SEPP Groundwaters of Victoria? • Where are nearest groundwater users or groundwater sensitive ecosystems? • Will de-watering be required (e.g. lowering the groundwater levels), or will the activity pit intersect the water table? • Will there be any potential effects on existing groundwater quality, and are there third party users of groundwater surrounding the activity? • Are there groundwater-dependent ecosystems located within the specified distances surrounding the activity area? • Is the activity within a Groundwater Restricted Quality Usage Zone, a Water Supply Protection area, or a Groundwater Management Area?

Discussion Topic	Details
Surface water	• What are the water quality objectives for the area defined in the SEPP Waters of Victoria? • Where are nearest water users or water sensitive ecosystems? • Are alterations to surface drainage required (e.g. waterway diversion) and if so, are they going to increase the potential for flooding of adjacent land? • Are soil, overburden or proposed extracted materials (e.g. soils etc.) susceptible to erosion (e.g. caused by clearing of vegetation, problem soils)? • Is there potential for soil and overburden stockpile to cause sedimentation outside of the activity boundary? • Is the activity area located within a potable water catchment?
Dams	• Will there be water storages (e.g. settlement pond, water storage, evaporation pond, bio-retention basin, etc.) or slimes dams on the activity area? • If yes, what is the type, area and embankment height of water storages or slimes dams? • Will the storage or dam be located on a waterway? • Will the dam receive runoff from a catchment upslope of the storage or dam? • Will any of the above storages hold water that is unlikely to meet the SEPP guidelines for surface water or groundwater (or the ANZECC guidelines where a constituent is not specified)? • Will any of the storages meet the criteria of a large dam in accordance with ANCOLD Guidelines? If yes, what is the type, area and embankment height of water storages or slimes dams and it's possible consequence category? • What impact could failure of a water storage or slimes dam have on public safety, infrastructure or the environment?
Geotechnical	• How will slope instability affect public safety, public infrastructure or environmental elements? • How can the site's lithology/geology and structural geology impact on slope stability? E.g. are there any active faults, dykes or shear zones (including adverse jointing) which may affect slope stability? • Is the overburden dispersive which may lead to long term erosion problems around the site? • What influence may seismic activity in the area have on slope stability? • Can elevated water levels in the batters have an impact on slope stability? • Are there areas where a perched water table may exist? • Could the proposed activity operation and excavation methods heighten the potential for slope instability, and would such instability have any impact outside the activity area? • Are there any historical voids (old mine underground workings, shafts, etc.) within the activity area? • Are there other adjacent land uses or features that could create triggers for land instability (e.g. neighbouring property performing blasting, surface water drainage near batter crest etc.)? • Will there be any crest loading, which may affect slope stability, such as an overburden dump or plant equipment situated near the crest of the open pit?
Environment – visual amenity (overburden/ waste rock)	• Will stockpiles and overburden dump be located within the activity area? • If yes, what is the volume of material and what is the proposed height of the largest stockpile/overburden dump?
Waste	• Will process wastewater be stored and treated within the activity area? • Will the operations (extraction and processing) generate hazardous wastes (e.g. grease, oils, putrescible waste, and batteries)?

Discussion Topic	Details
Fuel	• Will fuel (e.g. petrol, diesel) or other chemicals/additives be stored within the activity area? • Will refuelling, fuel storage and maintenance of machinery and equipment occur within activity area.
Acid mine drainage	• Will acid sulphate soils be exposed/oxygenated during the proposed activities? • Is there potential for sulphide minerals to be present or exposed during the proposed activity (such as from overburden, waste and remnant pit shells surfaces)?
Radiation	• Is any part of the operation (extracted or processed material) going to be legally radioactive in accordance with the *Radiation Act 2005*?
Site rehabilitation	• What is proposed for site rehabilitation and closure, and subsequent land use? • What is proposed for pit batter rehabilitation? • How will water storages and slimes dam facilities be rehabilitated? • What is proposed for surface water drainage and discharge from the activity area? • What land management or maintenance activities will be required after closure?

Appendix D CLA Site Photographs

ANGLESEA MINE ASH COVERING PROJECT EVALUATION - October 2018

As detailed in a letter sent to ERR on 20th November 2017 regarding ash covering within the mine, work commenced on this task in late November 2017 and was completed early Q2 2018. The following paragraph from that letter refers to the covering process:

'*While the ash materials provide a potential ameliorating effect on the pH of the water body, Alcoa proposes to use low permeability materials to cover the ash to minimise the risk of unacceptable changes in the long-term water body water quality. Erodible mine material (EMM) comprising silts and clay materials from the overburden disposal activities have historically been backfilled on-site and will be used as the cover material. The overburden material will be placed at a minimum thickness of 1 metre and compacted using the weight of the earthmoving equipment to provide a low permeability layer between the developing water body and ash deposits*.'

Both the ash disposal and covering process has largely been completed, with the remained exposed ash along the toe of the south wall eventually to be covered by final embankment reprofiling works. The covering process was completed using articulated 40 tonne haul trucks paddock dumping overburden material in a tight pattern and then having the heaps smoothed using a small dozer. This process was developed to ensure the 1 metre integrity without having continuous monitoring and was conservative in the design as the depth of the tipped material was such that it considered issues such as settlement (i.e. always well above the 1 metre target in the loose form).

To demonstrate compliance with the above 1 metre coverage undertaken, retrospective evaluations were undertaken using a small 30 tonne excavator to dig through the covering and expose the first signs of the covered ash. Test holes were completed over the entire covering area on a random and representative basis. The plan below. Note, due to the lack of a more recent aerial photograph, the accompanying plan depicts the test holes on a photograph taken prior to the commencement of the ash covering project.

Prior to measurements being taken, rainfall filled the holes leading to the need for the development of a jig that could be used to safely measure hole depth under the water. The following is a record of the evaluation, replicated the second time once the accumulated rainwater had gone from all but one of the test holes.

As indicated beside the various photographs of the individual holes, all test holes were at or above the minimum 1 metre covering requirement.

To: 'Marris, Nicci'
Cc: Rolland, Chris
Subject: RE: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
OK, if we are going to get the samples the day they are taken we can deal with them once they get here. This will change what bottles you need to take for the water samples though, please see the revised list below. This change is necessary as it important not to preserve the samples prior to the filtration.

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic

Just on further thing, the turn around surcharges are listed on the front of the quote, I have confirmed with our laboratory co-ordinator that we could report everything except CEC, PSD, TOC and the AMD parameters on a two day turn around from Monday if you require.

Kind regards,

Bronwyn Sheen

Subject: RE: RE: Quote for Analytical work - solid and water samples

Thank you very much Bronwyn,

We can do temperature and pH in the field, but we cannot do the in-field filtration. Can this be done at the Geelong lab prior to the samples being couriered to you?

In regard to the leachate testing, it is one soil leached with two different waters.

I will call through Geelong in the next hour to collect the sample bottles. We will raise a req based on a faster TAT now.

Thanks again
Nicci

Subject: EXT: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
Please find attached the quote for this work, there are just a few things to keep in mind.

We will required the field temperature and pH to be detailed on the CoC to enable us to calculate the ammonium.

The DOC, dissolved metals and ferrous iron all need to be field filtered to 0.45 um.

I have sent more bottles that you actually require, breaking down what you need to sample is as follows:

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial (filtered) ← DOC
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic (filtered) ← Dissolved Metals.
1 x 60 ml nitric acid preserved, red, plastic
1 x 60 ml hydrochloric acid preserved, maroon, plastic ← Ferrous.

Soils – per sample
2 x 150 ml soils jars, orange
1 x 500 ml snap lock bag (PSD)
1 x 250 ml snap lock bags (ASS)

Leachates – per sample (I'm not entirely sure if you require two different soils leached or just one soil leached with two different waters.)
2 x 250 ml soils jars , orange
3 x 1lt unpreserved, green, plastic

All of the bottles are jars have been delivered to our Geelong laboratory and are ready for collection whenever you are ready.

Just one more thing, when I originally spoke to Rebecca, she mentioned that you may need the water that is to be used for the leachate filtered prior to the leaching being performed. Is this still required? We could filter it to 0.7um which is the same as the post leaching filtration if required.

Kind regards,

Bronwyn Sheen

Cc: Rolland, Chris
Subject: RE: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
OK, if we are going to get the samples the day they are taken we can deal with them once they get here. This will change what bottles you need to take for the water samples though, please see the revised list below. This change is necessary as it important not to preserve the samples prior to the filtration.

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic

Just on further thing, the turn around surcharges are listed on the front of the quote, I have confirmed with our laboratory co-ordinator that we could report everything except CEC, PSD, TOC and the AMD parameters on a two day turn around from Monday if you require.

Kind regards,

Bronwyn Sheen

Subject: RE: RE: Quote for Analytical work - solid and water samples

Thank you very much Bronwyn,

We can do temperature and pH in the field, but we cannot do the in-field filtration. Can this be done at the Geelong lab prior to the samples being couriered to you?

In regard to the leachate testing, it is one soil leached with two different waters.

I will call through Geelong in the next hour to collect the sample bottles. We will raise a req based on a faster TAT now.

Thanks again
Nicci

Subject: EXT: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
Please find attached the quote for this work, there are just a few things to keep in mind.

We will required the field temperature and pH to be detailed on the CoC to enable us to calculate the ammonium.

The DOC, dissolved metals and ferrous iron all need to be field filtered to 0.45 um.

I have sent more bottles that you actually require, breaking down what you need to sample is as follows:

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial (filtered) ← DOC
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic (filtered) ← Dissolved Metals
1 x 60 ml nitric acid preserved, red, plastic
1 x 60 ml hydrochloric acid preserved, maroon, plastic ← Fe(II)

Soils – per sample
2 x 150 ml soils jars, orange
1 x 500 ml snap lock bag (PSD)
1 x 250 ml snap lock bags (ASS)

Leachates – per sample (I'm not entirely sure if you require two different soils leached or just one soil leached with two different waters.)
2 x 250 ml soils jars , orange
3 x 1lt unpreserved, green, plastic

All of the bottles are jars have been delivered to our Geelong laboratory and are ready for collection whenever you are ready.

Just one more thing, when I originally spoke to Rebecca, she mentioned that you may need the water that is to be used for the leachate filtered prior to the leaching being performed. Is this still required? We could filter it to 0.7um which is the same as the post leaching filtration if required.

Kind regards,

Bronwyn Sheen

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EP074-UT: Particular sample (EM-1607137-012) shows poor surrogates recovery due to the high moisture content.
- EP074-UT/EP071-EM/EP066-EM: Particular sample (EM-1607137-012), LOR has been raised due to the high moisture content.
- EG005C: Leachable Metal blank and LCS outside of criteria due to leaching solution provided. This has been confirmed.
- EP002: Leachable DOC blank Exceeds criteria due to leaching solution provided. This has been confirmed.
- EK061G: Sample EM1607137 #10 and #13 has been diluted for TKN analysis due to sample matrix. LOR's have been raised accordingly.
- EK055G: EM1607137 #13 Ammonia as N by Discrete analyser result for blank leaching solution is 0.18mg/L
- ED037 (Alkalinity): NATA accreditation does not cover the performance of this service.
- ED038 (Acidity): NATA accreditation does not cover the performance of this service.
- EG020F: Filtered iron results for EM1607137-010 have been confirmed by re-preparation and re-analysis.
- ALS is not NATA accredited for the analysis of ASLP due to non-NATA accredited leaching solution used.
- Ionic balances were calculated using: major anions - chloride, alkalinity and sulfate; and major cations - calcium, magnesium, potassium and sodium.
- ED045G: The presence of thiocyanate can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.
- This is a split batch of EM1607144 due to the urgent turnaround required for most analytes.
- EA016: Calculated TDS is determined from Electrical conductivity using a conversion factor of 0.65.
- Benzo(a)pyrene Toxicity Equivalent Quotient (TEQ) is the sum total of the concentration of the eight carcinogenic PAHs multiplied by their Toxicity Equivalence Factor (TEF) relative to Benzo(a)pyrene. TEF values are provided in brackets as follows: Benz(a)anthracene (0.1), Chrysene (0.01), Benzo(b+j) & Benzo(k)fluoranthene (0.1), Benzo(a)pyrene (1.0), Indeno(1.2.3.cd)pyrene (0.1), Dibenz(a.h)anthracene (1.0), Benzo(g.h.i)perylene (0.01). Less than LOR results for 'TEQ Zero' are treated as zero, for 'TEQ 1/2LOR' are treated as half the reported LOR, and for 'TEQ LOR' are treated as being equal to the reported LOR. Note: TEQ 1/2LOR and TEQ LOR will calculate as 0.6mg/Kg and 1.2mg/Kg respectively for samples with non-detects for all of the eight TEQ PAHs.

General Comments

This guideline comparison report **only** provides evaluation of total concentration data against upper limit thresholds for the 'Fill Material', 'C', 'B' Categories in Table 2 of EPA Publication IWRG621.

This guideline comparison report is **NOT** a soil classification report. Classification of soils as Fill Material, Category C, Category B or Category A requires consideration of a number of other factors including preliminary site investigation, sampling density and statistical calculations, as set out in EPA Publication IWRG 702.
Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

This guideline comparison report only provides evaluation data where chemical parameters specifically listed within the IWRG621 (2009) guideline are analysed by ALS using the **P-16 package in full**.
Red shading is applied where the result is equal to or greater than the guideline upper limit. Red shading is not applied to the 'Summary of Thresholds Reached or Exceeded'.

For the 'Summary of Thresholds Reached or Exceeded' to accurately function, all samples must be analysed and included in the 'Analytical Results' section of the following report. Please verify that all required IDs are listed and analysed.

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Summary of Thresholds Reached or Exceeded

EPA Victoria Publication IWRG 621 (2009)

No. of samples analysed	: 11		

NATA Accredited Laboratory 825
Accredited for compliance with ISO/IEC 17025.

NATA WORLD RECOGNISED ACCREDITATION

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Senior Inorganic Chemist	Melbourne Inorganics, Springvale, VIC
Nancy Wang	Senior Semivolatile Instrument Chemist	Melbourne Inorganics, Springvale, VIC
Nancy Wang	Senior Semivolatile Instrument Chemist	Melbourne Organics, Springvale, VIC

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

				Laboratory Duplicate (DUP) Report

Method Blank (MB) and Laboratory Control Spike (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Spike (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

ALS Environmental

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **EM1607137**	Page	: 1 of 18
Client	: **ALCOA AUSTRALIA ROLLED PRODUCTS**	Laboratory	: Environmental Division Melbourne
Contact	: MS NICCI MARRIS	Telephone	: +61-3-8549 9600
Project	: Alcoa Anglesea Waters and Solids	Date Samples Received	: 20-Jun-2016
Site	: Point Henry	Issue Date	: 23-Jun-2016
Sampler	: ----	No. of samples received	: 13
Order number	: 6681114	No. of samples analysed	: 11

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Duplicate outliers occur.**
- **Method Blank value outliers exist - please see following pages for full details.**
- **Laboratory Control outliers exist - please see following pages for full details.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **Surrogate recovery outliers exist for all regular sample matrices - please see following pages for full details.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **Quality Control Sample Frequency Outliers exist - please see following pages for full details.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **SOIL**

Compound Group Name	Laboratory Sample ID	Client Sample ID	Analyte	CAS Number	Data	Limits	Comment
Matrix Spike (MS) Recoveries							
EG005T: Total Metals by ICP-AES	EM1607137--006	PTH-16-0042	**Barium**	7440-39-3	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**
EG005T: Total Metals by ICP-AES	EM1607137--006	PTH-16-0042	**Manganese**	7439-96-5	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**
EP075B: Polynuclear Aromatic Hydrocarbons	EM1607082--032	Anonymous	**Pyrene**	129-00-0	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**

Matrix: **WATER**

Compound Group Name	Laboratory Sample ID	Client Sample ID	Analyte	CAS Number	Data	Limits	Comment
Method Blank (MB) Values							
EG005C: Leachable Metals by ICPAES	QC-492669-001	----	**Boron**	7440-42-8	29.9 mg/L	0.1 mg/L	**Blank result exceeds permitted value**
EG005C: Leachable Metals by ICPAES	QC-492671-001	----	**Boron**	7440-42-8	0.3 mg/L	0.1 mg/L	**Blank result exceeds permitted value**
EG005C: Leachable Metals by ICPAES	QC-492671-001	----	**Iron**	7439-89-6	31.8 mg/L	0.1 mg/L	**Blank result exceeds permitted value**
EG005C: Leachable Metals by ICPAES	QC-492671-001	----	**Manganese**	7439-96-5	1.1 mg/L	0.1 mg/L	**Blank result exceeds permitted value**

Leachable Metals by ICPAES	0	2	0.00	5.00	NEPM 2013 B3 & ALS QC Standard

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification
Analytical Methods	*Method*	*QC*	*Regular*	***Actual***	***Expected***	*Evaluation*	
Laboratory Duplicates (DUP)							
Acidity in Soil	ED038	1	4	**25.00**	**10.00**	✓	NEPM 2013 B3 & ALS QC Standard

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001	SOIL	In house: Referenced to Rayment and Higginson 4B1 (mod.) 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM (2013) Schedule B(3) (Method 103)
pH (1:5)	EA002	SOIL	In house: Referenced to APHA 4500H+. pH is determined on soil samples after a 1:5 soil/water leach. This method is compliant with NEPM (2013) Schedule B(3) (Method 103)
pH by PC Titrator	EA005-P	SOIL	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM (2013) Schedule B(3)
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM (2013) Schedule B(3) (Method 104)
Conductivity by PC Titrator	EA010-P	SOIL	In house: Referenced to APHA 2510 B. This procedure determines conductivity by automated ISE. This method is compliant with NEPM (2013) Schedule B(3)
Calculated TDS (from Electrical Conductivity)	EA016	SOIL	In house: Calculation from Electrical Conductivity (APHA 2510 B) using a conversion factor specified in the analytical report. This method is compliant with NEPM (2013) Schedule B(3)
Moisture Content	EA055-103	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 103-105 degrees C. This method is compliant with NEPM (2013) Schedule B(3) Section 7.1 and Table 1 (14 day holding time).
Alkalinity in Soil	ED037	SOIL	In house: Referenced to APHA 2320 B Alkalinity is determined and reported on a 1:5 soil/water leach.
Alkalinity by PC Titrator	ED037-P	SOIL	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM (2013) Schedule B(3)
Acidity in Soil	ED038	SOIL	In house: Referenced to APHA 2310B
Major Anions - Soluble	ED040S	SOIL	In house: Soluble Anions are determined off a 1:5 soil / water extract by ICPAES.
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	SOIL	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM (2013) Schedule B(3)
Chloride by Discrete Analyser	ED045G	SOIL	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride.in the presence of ferric ions the librated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm APHA 21st edition seal method 2 017-1-L april 2003
Major Cations - Dissolved	ED093F	SOIL	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations are determined by either ICP-AES or ICP-MS techniques. This method is compliant with NEPM (2013) Schedule B(3) Sodium Adsorption Ratio is calculated from Ca, Mg and Na which determined by ALS in house method QWI-EN/ED093F. This method is compliant with NEPM (2013) Schedule B(3) Hardness parameters are calculated based on APHA 2340 B. This method is compliant with NEPM (2013) Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Cations - soluble by ICP-AES	ED093S	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010 (ICPAES) Water extracts of the soil are analyzed for major cations by ICPAES. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM (2013) Schedule B(3)
Leachable Metals by ICPAES	EG005C	SOIL	In house: referenced to APHA 3120; USEPA SW 846 - 6010: The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM (2013) Schedule B(3)
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM (2013) Schedule B(3)
Leachable Mercury by FIMS	EG035C	SOIL	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Total Mercury by FIMS	EG035T	SOIL	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. Mercury in solids are determined following an appropriate acid digestion. Ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Hexavalent Chromium by Alkaline Digestion and DA Finish	EG048G	SOIL	In house: Referenced to USEPA SW846, Method 3060A. Hexavalent chromium is extracted by alkaline digestion. The digest is determined by photometrically by automatic discrete analyser, following pH adjustment. The instrument uses colour development using dephenylcarbazide. Each run of samples is measured against a five-point calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Ferrous Iron by Discrete Analyser	EG051G	SOIL	In house: Referenced to APHA 3500 Fe-B. A colorimetric determination based on the reaction between phenanthroline and ferrous iron at pH 3.2-3.3 to form an orange-red complex that is measured against a five-point calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Total Cyanide by Segmented Flow Analyser	EK026SF	SOIL	In house: Referenced to APHA 4500-CN C / ASTM D7511. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM (2013) Schedule B(3)
Fluoride by PC Titrator	EK040P	SOIL	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM (2013) Schedule B(3)
Total Fluoride	EK040T	SOIL	(In-house) Total fluoride is determined by ion specific electrode (ISE) in a solution obtained after a Sodium Carbonate / Potassium Carbonate fusion dissolution.

Analytical Methods	Method	Matrix	Method Descriptions
Ammonia as N by Discrete analyser	EK055G	SOIL	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Nitrite as N by Discrete Analyser	EK057G	SOIL	In house: Referenced to APHA 4500-NO2- B. Nitrite is determined by direct colourimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Nitrate as N by Discrete Analyser	EK058G	SOIL	In house: Referenced to APHA 4500-NO3- F. Nitrate is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results. This method is compliant with NEPM (2013) Schedule B(3)
Nitrite and Nitrate as N (NOx) by Discrete Analyser	EK059G	SOIL	In house: Referenced to APHA 4500-NO3- F. Combined oxidised Nitrogen (NO2+NO3) is determined by Chemical Reduction and direct colourimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Total Kjeldahl Nitrogen as N By Discrete Analyser	EK061G	SOIL	In house: Referenced to APHA 4500-Norg D (In house). An aliquot of sample is digested using a high temperature Kjeldahl digestion to convert nitrogenous compounds to ammonia. Ammonia is determined colorimetrically by discrete analyser. This method is compliant with NEPM (2013) Schedule B(3)
Total Nitrogen as N (TKN + Nox) By Discrete Analyser	EK062G	SOIL	In house: Referenced to APHA 4500-Norg / 4500-NO3-. This method is compliant with NEPM (2013) Schedule B(3)
Total Phosphorus as P By Discrete Analyser	EK067G	SOIL	In house: Referenced to APHA 4500-P H, Jirka et al (1976), Zhang et al (2006). This procedure involves sulphuric acid digestion of a sample aliquot to break phosphorus down to orthophosphate. The orthophosphate reacts with ammonium molybdate and antimony potassium tartrate to form a complex which is then reduced and its concentration measured at 880nm using discrete analyser. This method is compliant with NEPM (2013) Schedule B(3)
Ionic Balance by PCT DA and Turbi SO4 DA	EN055 - PG	SOIL	In house: Referenced to APHA 1030F. This method is compliant with NEPM (2013) Schedule B(3)
Dissolved Organic Carbon	EP002	SOIL	In house: Referenced to APHA 5310 B. This method is compliant with NEPM (2013) Schedule B(3) . Samples are combusted at high termperature in the presence of an oxidative catalyst. The evolved carbon dioxide is quantified using an IR detector.
PCB - VIC EPA 448.3 Screen	EP066-EM	SOIL	In house: Referenced to USEPA SW 846 - 8270D Extracts are analysed by Capillary GC/MS and quantification is by comparison against an established 5 point calibration curve. This method is compliant with NEPM (2013) Schedule B(3) (Method 504)
TRH - Semivolatile Fraction	EP071-EM	SOIL	In house: Referenced to USEPA SW 846 - 8015A Sample extracts are analysed by Capillary GC/FID and quantified against alkane standards over the range C10 - C40.
Volatile Organic Compounds - Ultra-trace	EP074-UT	SOIL	In house: Referenced to USEPA SW 846 - 8260B Extracts are analysed by Purge and Trap, Capillary GC/MS in partial SIM/Scan mode. Quantification is by comparison against an established multi-point calibration curves. This method is compliant with NEPM (2013) Schedule B(3) (Method 501)
Volatile Organic Compounds - Ultra-trace - Summations	EP074-UT-SUM	SOIL	Summation of MAHs and VHCs
Semivolatile Organic Compounds - Waste Classification	EP075-EM	SOIL	In house: Referenced to USEPA SW 846 - 8270D Extracts are analysed by Capillary GC/MS and quantification is by comparison against an established 5 point calibration curve. This technique is compliant with NEPM (2013) Schedule B(3) (Method 502)
SVOC - Waste Classification (Sums)	EP075-EM-SUM	SOIL	Summations for EP075 (EM variation)
pH by PC Titrator	EA005-P	WATER	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM (2013) Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Conductivity by PC Titrator	EA010-P	WATER	In house: Referenced to APHA 2510 B. This procedure determines conductivity by automated ISE. This method is compliant with NEPM (2013) Schedule B(3)
Calculated TDS (from Electrical Conductivity)	EA016	WATER	In house: Calculation from Electrical Conductivity (APHA 2510 B) using a conversion factor specified in the analytical report. This method is compliant with NEPM (2013) Schedule B(3)
Turbidity	EA045	WATER	In house: Referenced to APHA 2130 B. This method is compliant with NEPM (2013) Schedule B(3)
Redox Potential	EA075	WATER	In house: Ion selective electrode
Alkalinity by PC Titrator	ED037-P	WATER	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM (2013) Schedule B(3)
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	WATER	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM (2013) Schedule B(3)
Chloride by Discrete Analyser	ED045G	WATER	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride.in the presence of ferric ions the librated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm APHA 21st edition seal method 2 017-1-L april 2003
Major Cations - Dissolved	ED093F	WATER	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations are determined by either ICP-AES or ICP-MS techniques. This method is compliant with NEPM (2013) Schedule B(3) Sodium Adsorption Ratio is calculated from Ca, Mg and Na which determined by ALS in house method QWI-EN/ED093F. This method is compliant with NEPM (2013) Schedule B(3) Hardness parameters are calculated based on APHA 2340 B. This method is compliant with NEPM (2013) Schedule B(3)
Dissolved Metals by ICP-MS - Suite A	EG020A-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite A	EG020A-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Mercury by FIMS	EG035F	WATER	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) Samples are 0.45µm filtered prior to analysis. FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the filtered sample. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM (2013) Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Total Mercury by FIMS	EG035T	WATER	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the unfiltered sample. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Ferrous Iron by Discrete Analyser	EG051G	WATER	In house: Referenced to APHA 3500 Fe-B. A colorimetric determination based on the reaction between phenanthroline and ferrous iron at pH 3.2-3.3 to form an orange-red complex that is measured against a five-point calibration curve. This method is compliant with NEPM (2013) Schedule B(3)
Fluoride by PC Titrator	EK040P	WATER	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM (2013) Schedule B(3)
Ammonia as N by Discrete analyser	EK055G	WATER	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Nitrite as N by Discrete Analyser	EK057G	WATER	In house: Referenced to APHA 4500-NO2- B. Nitrite is determined by direct colourimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Nitrate as N by Discrete Analyser	EK058G	WATER	In house: Referenced to APHA 4500-NO3- F. Nitrate is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results. This method is compliant with NEPM (2013) Schedule B(3)
Nitrite and Nitrate as N (NOx) by Discrete Analyser	EK059G	WATER	In house: Referenced to APHA 4500-NO3- F. Combined oxidised Nitrogen (NO2+NO3) is determined by Chemical Reduction and direct colourimetry by Discrete Analyser. This method is compliant with NEPM (2013) Schedule B(3)
Total Kjeldahl Nitrogen as N By Discrete Analyser	EK061G	WATER	In house: Referenced to APHA 4500-Norg D (In house). An aliquot of sample is digested using a high temperature Kjeldahl digestion to convert nitrogenous compounds to ammonia. Ammonia is determined colorimetrically by discrete analyser. This method is compliant with NEPM (2013) Schedule B(3)
Total Nitrogen as N (TKN + Nox) By Discrete Analyser	EK062G	WATER	In house: Referenced to APHA 4500-Norg / 4500-NO3-. This method is compliant with NEPM (2013) Schedule B(3)
Total Phosphorus as P By Discrete Analyser	EK067G	WATER	In house: Referenced to APHA 4500-P H, Jirka et al (1976), Zhang et al (2006). This procedure involves sulphuric acid digestion of a sample aliquot to break phosphorus down to orthophosphate. The orthophosphate reacts with ammonium molybdate and antimony potassium tartrate to form a complex which is then reduced and its concentration measured at 880nm using discrete analyser. This method is compliant with NEPM (2013) Schedule B(3)
Ionic Balance by PCT DA and Turbi SO4 DA	EN055 - PG	WATER	In house: Referenced to APHA 1030F. This method is compliant with NEPM (2013) Schedule B(3)
Dissolved Organic Carbon	EP002	WATER	In house: Referenced to APHA 5310 B. This method is compliant with NEPM (2013) Schedule B(3) . Samples are combusted at high termperature in the presence of an oxidative catalyst. The evolved carbon dioxide is quantified using an IR detector.
Total Organic Carbon	EP005	WATER	In house: Referenced to APHA 5310 B, The automated TOC analyzer determines Total and Inorganic Carbon by IR cell. TOC is calculated as the difference. This method is compliant with NEPM (2013) Schedule B(3)

Preparation Methods	Method	Matrix	Method Descriptions
NaOH leach for CN in Soils	CN-PR	SOIL	In house: APHA 4500 CN. Samples are extracted by end-over-end tumbling with NaOH.

Preparation Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001-PR	SOIL	In house: Referenced to Rayment and Higginson 4B1, 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM (2013) Schedule B(3) (Method 103)
Alkaline digestion for Hexavalent Chromium	EG048PR	SOIL	In house: Referenced to USEPA SW846, Method 3060A.
Total Fluoride	EK040T-PR	SOIL	In house: Samples are fused with Sodium Carbonate / Potassium Carbonate flux.
TKN/TP Digestion	EK061/EK067	SOIL	In house: Referenced to APHA 4500 Norg - D; APHA 4500 P - H. This method is compliant with NEPM (2013) Schedule B(3)
Digestion for Total Recoverable Metals in TCLP Leachate	EN25C	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM (2013) Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of distilled water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes	EN60a	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
ASLP for Volatile Analytes (Zero Headspace Extraction)	EN60Za	SOIL	In house QWI-EN/60 referenced to AS4439.2 Preparation of Leachates
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM (2013) Schedule B(3) (Method 202)
Methanolic Extraction of Soils - Ultra-trace.	ORG16-UT	SOIL	In house: Referenced to USEPA SW 846 - 5030A. 5g of solid is shaken with surrogate and 10mL methanol prior to analysis by Purge and Trap - GC/MS.
Tumbler Extraction of Solids	ORG17	SOIL	In house: Mechanical agitation (tumbler). 10g of sample, Na2SO4 and surrogate are extracted with 30mL 1:1 DCM/Acetone by end over end tumble. The solvent is decanted, dehydrated and concentrated (by KD) to the desired volume for analysis.
Tumbler Extraction of Solids - VIC EPA Screen	ORG17A-EM	SOIL	In house: Mechanical agitation (tumbler). 20g of sample, Na2SO4 and surrogate are extracted with 150mL 1:1 DCM/Acetone by end over end tumble. The solvent is decanted, dehydrated and concentrated (by KD) to the desired volume for analysis.
TKN/TP Digestion	EK061/EK067	WATER	In house: Referenced to APHA 4500 Norg - D; APHA 4500 P - H. This method is compliant with NEPM (2013) Schedule B(3)
Digestion for Total Recoverable Metals	EN25	WATER	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM (2013) Schedule B(3)

Subject: RE: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
OK, if we are going to get the samples the day they are taken we can deal with them once they get here. This will change what bottles you need to take for the water samples though, please see the revised list below. This change is necessary as it important not to preserve the samples prior to the filtration.

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic

Just on further thing, the turn around surcharges are listed on the front of the quote, I have confirmed with our laboratory co-ordinator that we could report everything except CEC, PSD, TOC and the AMD parameters on a two day turn around from Monday if you require.

Kind regards,

Bronwyn Sheen

Thank you very much Bronwyn,

We can do temperature and pH in the field, but we cannot do the in-field filtration. Can this be done at the Geelong lab prior to the samples being couriered to you?

In regard to the leachate testing, it is one soil leached with two different waters.

I will call through Geelong in the next hour to collect the sample bottles. We will raise a req based on a faster TAT now.

Thanks again
Nicci

Subject: EXT: RE: Quote for Analytical work - solid and water samples

Hi Nicci,
Please find attached the quote for this work, there are just a few things to keep in mind.

We will required the field temperature and pH to be detailed on the CoC to enable us to calculate the ammonium.

The DOC, dissolved metals and ferrous iron all need to be field filtered to 0.45 um.

I have sent more bottles that you actually require, breaking down what you need to sample is as follows:

Waters – per sample
1 x 500 ml unpreserved, green, plastic
1 x 60 ml sulphuric acid preserved, purple, plastic
1 x 40 ml sulphuric acid preserved, purple, vial (filtered) ← DOC
1 x 40 ml sulphuric acid preserved, purple, vial
1 x 60 ml nitric acid preserved, red, plastic (filtered) ← Dissolved Metals
1 x 60 ml nitric acid preserved, red, plastic
1 x 60 ml hydrochloric acid preserved, maroon, plastic ← Ferrous

Soils – per sample
2 x 150 ml soils jars, orange
1 x 500 ml snap lock bag (PSD)
1 x 250 ml snap lock bags (ASS)

Leachates – per sample (I'm not entirely sure if you require two different soils leached or just one soil leached with two different waters.)
2 x 250 ml soils jars , orange
3 x 1lt unpreserved, green, plastic

All of the bottles are jars have been delivered to our Geelong laboratory and are ready for collection whenever you are ready.

Just one more thing, when I originally spoke to Rebecca, she mentioned that you may need the water that is to be used for the leachate filtered prior to the leaching being performed. Is this still required? We could filter it to 0.7um which is the same as the post leaching filtration if required.

Kind regards,

Bronwyn Sheen

Kim McCabe	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Satishkumar Trivedi	Acid Sulfate Soils Supervisor	Brisbane Acid Sulphate Soils, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- **29/6/2016: This report has been amended as it has been identified that an incorrect CEC methodology (ED008) has been applied due to a laboratory error. ALS method ED006 has now been scheduled, with results expected to be finalised by Friday, 1 July 2016.**
- This is a split batch of EM1607137 due to an urgent turnaround request for most analytes.
- ASS: EA013 (ANC) Fizz Rating: 0- None; 1- Slight; 2- Moderate; 3- Strong; 4- Very Strong; 5- Lime.
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **EM1607144**	Page	: 1 of 4
Amendment	: **1**		
Client	: **ALCOA AUSTRALIA ROLLED PRODUCTS**	Laboratory	: Environmental Division Melbourne
Contact	: MS NICCI MARRIS	Telephone	: +61-3-8549 9636
Project	: Alcoa Anglesea Waters and Solids	Date Samples Received	: 20-Jun-2016
Site	: Point Henry	Issue Date	: 04-Jul-2016
Sampler	: ----	No. of samples received	: 4
Order number	: 6681114	No. of samples analysed	: 4

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Duplicate outliers occur.**
- **NO Laboratory Control outliers occur.**
- **NO Matrix Spike outliers occur.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **NO Analysis Holding Time Outliers exist.**

Outliers : Frequency of Quality Control Samples

- **NO Quality Control Sample Frequency Outliers exist.**

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
Net Acid Production Potential	EA009	SOIL	In house: Referenced to Coastech Research (Canada)(Mod.). NAPP = Acid Production Potential (APP or MAP-Maximum Acid Potential) minus Neutralising Capacity (ANC). NAPP may be +ve, zero or -ve.
Net Acid Generation	EA011	SOIL	In house: Referenced to Miller (1998) Titremetric procedure determines net acidity in a soil following peroxide oxidation. Titrations to both pH 4.5 and pH 7 are reported.
Acid Neutralising Capacity (ANC)	EA013	SOIL	In house: Referenced to USEPA 600/2-78-054, I. Miller (2000). A fizz test is done to semiquanititatively estimate the likely reactivity. The soil is then reacted with an known excess quanitity of an appropriate acid. Titration determines the acid remaining, and the ANC can be calculated from comparison with a blank titration.
Particle Size Analysis by Hydrometer	EA150H	SOIL	Particle Size Analysis by Hydrometer according to AS1289.3.6.3 - 2003
Exchangeable Cations on Alkaline Soils	ED006	SOIL	In house: Referenced to Rayment & Lyons (2011) Method 15C1. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with alcoholic ammonium chloride at pH 8.5. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil.
Sulfur - Total as S (LECO)	ED042T	SOIL	In house: Dried and pulverised sample is combusted in a high temperature furnace in the presence of strong oxidants / catalysts. The evolved S (as SO2) is measured by infra-red detector
Total Organic Carbon	EP003	SOIL	In house C-IR17. Dried and pulverised sample is reacted with acid to remove inorganic Carbonates, then combusted in a LECO furnace in the presence of strong oxidants / catalysts. The evolved (Organic) Carbon (as CO2) is automaticaly measured by infra-red detector.

Preparation Methods	Method	Matrix	Method Descriptions
Exchangeable Cations Preparation Method (Alkaline Soils)	ED006PR	SOIL	In house: Referenced to Rayment and Lyons 2011 method 15C1.
Exchangeable Cations Preparation Method	ED007PR	SOIL	In house: Referenced to Rayment & Higginson (1992) method 15A1. A 1M NH4Cl extraction by end over end tumbling at a ratio of 1:20. There is no pretreatment for soluble salts. Extracts can be run by ICP for cations.
Drying at 85 degrees, bagging and labelling (ASS)	EN020PR	SOIL	In house
Dry and Pulverise (up to 100g)	GEO30	SOIL	#

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Spike (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Spike (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Sub-Matrix: **SOIL**

				Method Blank (MB) Report	Laboratory Control Spike (LCS) Report

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

- **No Matrix Spike (MS) or Matrix Spike Duplicate (MSD) Results are required to be reported.**

General Comments

- This report contains the following information:
  - Sample Container(s)/Preservation Non-Compliances
  - Summary of Sample(s) and Requested Analysis
  - Proactive Holding Time Report
  - Requested Deliverables
- **Please direct any queries related to sample condition / numbering / breakages to Client Services.**
- Sample Disposal - Aqueous (3 weeks), Solid (2 months) from receipt of samples.
- **Analytical work for this work order will be conducted at ALS Springvale.**
- **Please refer to the Proactive Holding Time Report table below which summarises breaches of recommended holding times that have occurred prior to samples/instructions being received at the laboratory. The laboratory will process these samples unless instructions are received from you indicating you do not wish to proceed. The absence of this summary table indicates that all samples have been received within the recommended holding times for the analysis requested.**
- Please be aware that APHA/NEPM recommends water and soil samples be chilled to less than or equal to 6°C for chemical analysis, and less than or equal to 10°C but unfrozen for Microbiological analysis. Where samples are received above this temperature, it should be taken into consideration when interpreting results. Refer to ALS EnviroMail 85 for ALS recommendations of the best practice for chilling samples after sampling and for maintaining a cool temperature during transit.

Sample Container(s)/Preservation Non-Compliances

All comparisons are made against pretreatment/preservation AS, APHA, USEPA standards.

- **No sample container / preservation non-compliance exists.**

Summary of Sample(s) and Requested Analysis

Some items described below may be part of a laboratory process necessary for the execution of client requested tasks. Packages may contain additional analyses, such as the determination of moisture content and preparation tasks, that are included in the package.
If no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component

No. of samples analysed	: 23		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Senior Inorganic Chemist	Melbourne Inorganics, Springvale, VIC
Jarwis Nheu	Non-Metals Team Leader	Melbourne Inorganics, Springvale, VIC
Kim McCabe	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	WB Water Lab Brisbane, Stafford, QLD
Nikki Stepniewski	Senior Inorganic Instrument Chemist	Melbourne Inorganics, Springvale, VIC

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ED009-X (Standard Anions - Extended Method –by IC): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EK040-P,ED038-P,EA010-P: EM2118436 #39. Insufficient sample provided to analyse fluoride,conductivity & alkalinity duplicate.
- EK040-P: EM2118436 #6. Insufficient sample provided to analyse fluoride Matrix spilke.
- EG050G-C: EM2118739 sample #28 poor matrix spike recovery for Hexavalent Chromium due to matrix effects. Confirmed by re-analysis.
- EG050G-C: EM2118436 sample #3 poor matrix spike recovery for Hexavalent Chromium due to matrix effects. Confirmed by re-analysis.
- EG048G: EM2118436 sample #3 poor insoluble matrix spike recovery for Hexavalent Chromium due to sample matrix interferences. Confirmed by re-analysis.
- ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
- EK061G: EM2118436 #6,12,16,20,26,30,33,35-38,40 Samples required dilution prior to analysis for TKN due to sample matrix. LOR has been adjusted accordingly.
- EA015H: EM2118436 #31, #34, #37-#39: TDS by method EA-015 may bias high due to the presence of fine particulate matter, which may pass through the prescribed GF/C paper.
- EK061G: EM2118436 #2 & 22 Poor duplicate precision for TKN due to sample heterogeneity. Confirmed by re-extraction and re-analysis.
- EP004: EM2118436 #3: Poor matrix spike recovery for organic matter and total organic carbon due to matrix effects.
- EP004: EM2118436 #3 Poor matrix spike recovery for Organic Matter & Total Organic Carbon due to matrix effects.
- EK067G: EM2118436 #16,22,40 Samples required dilution prior to analysis for Total phosphorus due to sample matrix. LOR has been adjusted accordingly.
- ED045G: The presence of Thiocyanate, Thiosulfate and Sulfite can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.
- ASS: EA013 (ANC) Fizz Rating: 0- None; 1- Slight; 2- Moderate; 3- Strong; 4- Very Strong; 5- Lime.
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).
- EN60: Where leachable PFAS analysis is requested, centrifugation rather than pressure filtration is used as the default approach for removal of particulates, in line with AS 4439.3.
- EN60-DI: Where leachable PFAS analysis is requested, centrifugation rather than pressure filtration is used as the default approach for removal of particulates, in line with AS 4439.3.

QUALITY CONTROL REPORT

Work Order	: **EM2118436**	Page	: 1 of 22
Client	: **ALCOA Australia**	Laboratory	: Environmental Division Melbourne
Contact	: CHRIS SMITT	Contact	: Peter Ravlic
Address	: POINT HENRY WORKS P.O.BOX 460 GEELONG VIC, AUSTRALIA 3220	Address	: 4 Westall Rd Springvale VIC Australia 3171
Telephone	: ----	Telephone	: +6138549 9645
Project	: Alcoa Anglesea	Date Samples Received	: 15-Sep-2021
Order number	: ----	Date Analysis Commenced	: 20-Sep-2021
C-O-C number	: ----	Issue Date	: 29-Sep-2021
Sampler	: MATT RUSS		
Site	: ANGLESEA		
Quote number	: ME/638/21		
No. of samples received	: 40		
No. of samples analysed	: 23		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Senior Inorganic Chemist	Melbourne Inorganics, Springvale, VIC
Jarwis Nheu	Non-Metals Team Leader	Melbourne Inorganics, Springvale, VIC
Kim McCabe	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	WB Water Lab Brisbane, Stafford, QLD
Nikki Stepniewski	Senior Inorganic Instrument Chemist	Melbourne Inorganics, Springvale, VIC

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

Sub-Matrix: **SOIL**

ALS Environmental

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **EM2118436**	Page	: 1 of 25
Client	: **ALCOA Australia**	Laboratory	: Environmental Division Melbourne
Contact	: CHRIS SMITT	Telephone	: +6138549 9645
Project	: Alcoa Anglesea	Date Samples Received	: 15-Sep-2021
Site	: ANGLESEA	Issue Date	: 29-Sep-2021
Sampler	: MATT RUSS	No. of samples received	: 40
Order number	: ----	No. of samples analysed	: 23

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Laboratory Control outliers occur.**
- **Duplicate outliers exist - please see following pages for full details.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **NO Analysis Holding Time Outliers exist.**

Outliers : Frequency of Quality Control Samples

- **Quality Control Sample Frequency Outliers exist - please see following pages for full details.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

EG005(ED093)C: Leachable Metals by ICPAES	EM2118436--003	ANG-21-0182	**Iron**	7439-89-6	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**
ED041G: Sulfate (Turbidimetric) as SO4 2- by DA	EM2118436--040	ANG-21-0207	**Sulfate as SO4 - Turbidimetric**	14808-79-8	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**
EG050G: Hexavalent Chromium by Discrete Analyser	EM2118436--003	ANG-21-0182	**Hexavalent Chromium**	18540-29-9	1.1 %	71.7-128%	**Recovery less than lower data quality objective**
EG050G: Hexavalent Chromium by Discrete Analyser	EM2118739--028	Anonymous	**Hexavalent Chromium**	18540-29-9	67.3 %	71.7-128%	**Recovery less than lower data quality objective**

Outliers : Frequency of Quality Control Samples

Matrix: **WATER**

Quality Control Sample Type	Count		Rate (%)		Quality Control Specification
Method	QC	Regular	Actual	Expected	
Laboratory Duplicates (DUP)					
Dissolved Organic Carbon	1	11	9.09	10.00	NEPM 2013 B3 & ALS QC Standard
Fluoride by PC Titrator	3	40	7.50	10.00	NEPM 2013 B3 & ALS QC Standard
Matrix Spikes (MS)					
Fluoride by PC Titrator	1	40	2.50	5.00	NEPM 2013 B3 & ALS QC Standard

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001	SOIL	In house: Referenced to Rayment and Lyons 4B3 (mod.) or 4B4 (mod.) 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Conductivity by PC Titrator	EA010-P	SOIL	In house: Referenced to APHA 2510 B. This procedure determines conductivity by automated ISE. This method is compliant with NEPM Schedule B(3)
Acid Neutralising Capacity (ANC)	EA013	SOIL	In house: Referenced to USEPA 600/2-78-054, I. Miller (2000). A fizz test is done to semiquanititatively estimate the likely reactivity. The soil is then reacted with an known excess quanitity of an appropriate acid. Titration determines the acid remaining, and the ANC can be calculated from comparison with a blank titration.
Total Soluble Salts	EA014	SOIL	In house: The concentration of Total Soluble Salts in a soil is calculated from the Electrical conductivity of a water extract. This method is compliant with NEPM Schedule B(3).
Total Dissolved Solids (High Level)	EA015H	SOIL	In house: Referenced to APHA 2540C. A gravimetric procedure that determines the amount of `filterable` residue in an aqueous sample. A well-mixed sample is filtered through a glass fibre filter (1.2um). The filtrate is evaporated to dryness and dried to constant weight at 180+/-5C. This method is compliant with NEPM Schedule B(3)
Moisture Content	EA055	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 105-110 degrees C. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations on Alkaline Soils	* ED006	SOIL	In house: Referenced to Soil Survey Test Method C5. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with alcoholic ammonium chloride at pH 8.5. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil.
Exchangeable Cations	ED007	SOIL	In house: Referenced to Rayment & Lyons Method 15A1. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations with pre-treatment	ED008	SOIL	In house: Referenced to Rayment & Lyons Method 15A2. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Standard Anions (Extended Method)	* ED009-X	SOIL	In-house: Referenced to APHA 4110. A soil sample is leached with 1 part to five parts of deionised water and the leachate subject to analysis by ion chromatography with conductivity detection. This method is compliant with NEPM Schedule B(3).
Iodide by Ion Selective Electrode (ISE)	ED010	SOIL	In house: A high ionic strength of the liquid sample is maintained with the addition of sodium nitrate and Iodide is measured with an ion selective electrode.
Alkalinity by PC Titrator	ED037-P	SOIL	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Sulfate - Calcium Phosphate Soluble	ED040N	SOIL	In house: The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulfate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	SOIL	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	SOIL	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride.in the presence of ferric ions the librated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm APHA seal method 2 017-1-L
Leachable Major Cations	ED093C	SOIL	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations in leachates are determined by either ICP-AES or ICP-MS techniques.
Cations - soluble by ICP-AES	ED093S	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010 (ICPAES) Water extracts of the soil are analyzed for major cations by ICPAES. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3).
Water Leachable Major Cations	ED093W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010; ALS QWI-EN/EG005, QWI-EN/ED093. The ICPAES technique quickly breaks the sample down into atoms and ions under extremely hot plasma. Atoms are then ionised, emitting a characteristic spectrum. The spectrometer then separates the wavelengths, prior to comparison of intensities against matrix matched standards for quantification.
Leachable Metals by ICPAES	EG005C	SOIL	In house: referenced to APHA 3120; USEPA SW 846 - 6010: The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Water Leachable Metals by ICPAES	EG005W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Leachable Mercury by FIMS	EG035C	SOIL	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).

Analytical Methods	Method	Matrix	Method Descriptions
Total Mercury by FIMS	EG035T	SOIL	In house: Referenced to AS 3550, APHA 3112 Hg - B (Flow-injection (SnCl2) (Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. Mercury in solids are determined following an appropriate acid digestion. Ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3)
Hexavalent Chromium by Alkaline Digestion and DA Finish	EG048G	SOIL	In house: Referenced to USEPA SW846, Method 3060. Hexavalent chromium is extracted by alkaline digestion. The digest is determined by photometrically by automatic discrete analyser, following pH adjustment. The instrument uses colour development using dephenylcarbazide. Each run of samples is measured against a five-point calibration curve. This method is compliant with NEPM Schedule B(3)
Hexavalent Chromium by Discrete Analyser - Leachable	EG050G-C	SOIL	In house: Referenced to APHA 3500 Cr-A & B. Hexavalent chromium is determined directly on leachate samples by Descrete Analyser as received by pH adjustment and colour development using dephenylcarbazide. Each run of samples is measured against a five-point calibration curve. This method is compliant with NEPM Schedule B(3).
Total Cyanide by Segmented Flow Analyser	EK026SF	SOIL	In house: Referenced to APHA 4500-CN C / ASTM D7511 / ISO 14403. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM Schedule B(3).
Cyanide Amenable to Chlorination (Segmented Flow Analyser)	EK030SF	SOIL	In house: Referenced to APHA 4500-CN G (prep), 4500-CN O (det.). The sample is pretreated by contact with chlorine (as hypochlorite) prior to determination of total cyanide. The measured parameter is the difference between total cyanide determined on an untreated sample and total cyanide determined post-chlorination. This method is compliant with NEPM Schedule B(3)
Fluoride by PC Titrator	EK040P	SOIL	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Total Fluoride	EK040T	SOIL	(In-house) Total fluoride is determined by ion specific electrode (ISE) in a solution obtained after a Sodium Carbonate / Potassium Carbonate fusion dissolution.
Buchi Ammonia	EK055	SOIL	In house: Referenced to APHA 4500-NH3 B&G, H Samples are steam distilled (Buchi) prior to analysis and quantified using titration, FIA or Discrete Analyser.
Ammonia as N by Discrete analyser	EK055G	SOIL	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Nitrite as N by Discrete Analyser	EK057G	SOIL	In house: Referenced to APHA 4500-NO2- B. Nitrite is determined by direct colourimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Nitrate as N - Soluble by Discrete Analyser	EK058G	SOIL	In house: Referenced to APHA 4500-NO3- F. Nitrate in the 1:5 soil:water extract is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results.

Analytical Methods	Method	Matrix	Method Descriptions
Nitrite and Nitrate as N (NOx) by Discrete Analyser	EK059G	SOIL	In house: Referenced to APHA 4500-NO3- F. Combined oxidised Nitrogen (NO2+NO3) is determined by Chemical Reduction and direct colourimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Total Kjeldahl Nitrogen as N By Discrete Analyser	EK061G	SOIL	In house: Referenced to APHA 4500-Norg D (In house). An aliquot of sample is digested using a high temperature Kjeldahl digestion to convert nitrogenous compounds to ammonia. Ammonia is determined colorimetrically by discrete analyser. This method is compliant with NEPM Schedule B(3)
Total Nitrogen as N (TKN + Nox) By Discrete Analyser	EK062G	SOIL	In house: Referenced to APHA 4500-Norg / 4500-NO3-. This method is compliant with NEPM Schedule B(3)
Total Phosphorus as P By Discrete Analyser	EK067G	SOIL	In house: Referenced to APHA 4500-P H, Jirka et al, Zhang et al. This procedure involves sulphuric acid digestion of a sample aliquot to break phosphorus down to orthophosphate. The orthophosphate reacts with ammonium molybdate and antimony potassium tartrate to form a complex which is then reduced and its concentration measured at 880nm using discrete analyser. This method is compliant with NEPM Schedule B(3)
Dissolved Organic Carbon	EP002	SOIL	In house: Referenced to APHA 5310 B. This method is compliant with NEPM Schedule B(3). Samples are combusted at high termperature in the presence of an oxidative catalyst. The evolved carbon dioxide is quantified using an IR detector.
Organic Matter	EP004	SOIL	In house: Referenced to AS1289.4.1.1. Dichromate oxidation method after Walkley and Black. This method is compliant with NEPM Schedule B(3)

Preparation Methods	Method	Matrix	Method Descriptions
NaOH leach for CN in Soils	CN-PR	SOIL	In house: APHA 4500 CN. Samples are extracted by end-over-end tumbling with NaOH.
pH in soil using a 0.01M CaCl2 extract	EA001-PR	SOIL	In house: Referenced to Rayment and Lyons 4B1, 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations Preparation Method (Alkaline Soils)	ED006PR	SOIL	In house: Referenced to Rayment and Lyons method 15C1.
Exchangeable Cations Preparation Method	ED007PR	SOIL	In house: Referenced to Rayment & Lyons method 15A1. A 1M NH4Cl extraction by end over end tumbling at a ratio of 1:20. There is no pretreatment for soluble salts. Extracts can be run by ICP for cations.
Calcium Phosphate Extraction for Sulphate as SO4 2-	ED040NPR	SOIL	The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulphate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).
Alkaline digestion for Hexavalent Chromium	EG048PR	SOIL	In house: Referenced to USEPA SW846, Method 3060A.
Total Fluoride	EK040T-PR	SOIL	In house: Samples are fused with Sodium Carbonate / Potassium Carbonate flux.
TKN/TP Digestion	EK061/EK067	SOIL	In house: Referenced to APHA 4500 Norg- D; APHA 4500 P - H. Macro Kjeldahl digestion.
Drying at 85 degrees, bagging and labelling (ASS)	EN020PR	SOIL	In house
Digestion for Total Recoverable Metals in TCLP Leachate	EN25C	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)

Preparation Methods	Method	Matrix	Method Descriptions
Digestion for Total Recoverable Metals in DI Water Leachate	EN25W	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
1:5 solid / water leach following drying at 40°C	EN34-AD	SOIL	10 g of 40°C dried soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes - Plastic Leaching Vessel	EN60a-P	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates.
Deionised Water Leach - Plastic Leaching Vessel	EN60-DIa-P	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
ASLP for Volatile Analytes (Zero Headspace Extraction)	EN60Za	SOIL	In house QWI-EN/60 referenced to AS4439.2 Preparation of Leachates
Deionised Water Leach - Zero Headspace Extraction	EN60Z-DIa	SOIL	In house QWI-EN/60 referenced to AS4439.2 Preparation of Leachates
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).
Organic Matter	EP004-PR	SOIL	In house: Referenced to AS1289.4.1.1. Dichromate oxidation method after Walkley and Black. This method is compliant with NEPM Schedule B(3).

EXTERNAL EMAIL*

Hi,

Please see analysis below. Please also do CEC.

Many thanks

Parameter	ALS Code	Technique/ Method Reference	Limit Of Reporting (LOR)
Total Mercury	EG035T (solids)	APHA 3112 Hg - B	0.1 mg/kg
1:5 Leach	EN34	In house	0.1 g
Electrical Conductivity (1:5)	EA010 (solids)	Various	1 µS/cm
Ammonia as N	EK055 (solids)	APHA 4500-NH3 B/G/H	20 mg/kg
Total Metals -Al, Sb, As, Ba, Be, B, Cd, Cr, Co, Cu, Fe, Pb, Mn, Mo, Ni, Se, Zn	EG005T (solids)	USEPA 6010	1 - 50 mg/kg
Total Cyanide	EK026SF (Solids)	Various	1 mg/kg
Total Fluoride	EK040T	In house	40 mg/kg
Organic Matter & Total Organic Carbon (Calc.) (Walkley Black)	EP004 (Carbon)	AS1289.4.1.1	0.5 %
pH (CaCl)	EA001	Various	0.1 pH Unit
Cyanide Amenable to Chlorination	EK030SF	Various	1 mg/kg
Major Cations (Ca, Mg, Na, K)	NT-1S	USEPA 6010, In house	10 mg/kg, 1 %
Total Hexavalent Chromium (Alkaline digestion)	EG048G	USEPA 3060	0.5 mg/kg
Total N + Total P	NT-11S	Various	1 %, 0.1 - 20 mg/kg
Iodide	ED009-X	APHA 4110	0.05 mg/kg
NO2 and NO3	NT-4S	Various	1 %, 0.1 mg/kg
Major Anions (Cl, SO4) (melb)	NT-2S-EM	Various	Various
Alkalinity - Acid Neutralising Capacity (ANC)	EA013	USEPA 600/2-78-054 & Miller	Various
Drying at 85 degrees, bagging and labelling (ASS)	EN020PR	In house	0.1 g
Total Soluble Salts	EA014	Calculation	5 mg/kg

Hi,

Please ignore the 1:5 leach and drying at 85 degrees bagging and labelling.

Please complete all other listed analysis plus CEC.

826015
C/O EF
22/9/21.

Many thanks,

Matt Russ

Subject: Eurofins Sample Receipt Advice - Report 826015 : Site ALCOA ANGLESEA

PLEASE CONFIRM 1:5 LEACH AND DRYING AT 85 DEGREES BAGGING AND LABELLING (ASS)

Dear Valued Client,

Please find attached a Sample Receipt Advice (SRA), a Summary Sheet and a scanned copy of your Chain-of-Custody (COC). It is important that you check this documentation to ensure that the details are correct such as the Client Job Number, Turn Around Time, any comments in the Notes section and sample numbers as well as the requested analysis. If there are any irregularities then please contact your Eurofins Analytical Services Manager as soon as possible to make certain that they get changed.

Regards

Joanne Devine

Sample Receipt Advice

Company name:	EHS Support Pty Ltd
Contact name:	Matt Russ
Project name:	ALCOA ANGLESEA
Project ID:	Not provided
Turnaround time:	5 Day
Date/Time received	Sep 20, 2021 4:00 PM
Eurofins reference	826015

Sample Information

✓	A detailed list of analytes logged into our LIMS, is included in the attached summary table.
✓	All samples have been received as described on the above COC.
✓	COC has been completed correctly.
✓	Attempt to chill was evident.
✓	Appropriately preserved sample containers have been used.
✓	All samples were received in good condition.
✓	Samples have been provided with adequate time to commence analysis in accordance with the relevant holding times.
✓	Appropriate sample containers have been used.
✓	Sample containers for volatile analysis received with zero headspace.
✗	Split sample sent to requested external lab.
✗	Some samples have been subcontracted.
N/A	Custody Seals intact (if used).

Notes

Contact

If you have any questions with respect to these samples, please contact your Analytical Services Manager:

Michael Morrison on phone : 03 8564 5933 or by email: MichaelMorrison@eurofins.com

Results will be delivered electronically via email to Matt Russ - matt.russ@ehs-support.com.

Note: A copy of these results will also be delivered to the general EHS Support Pty Ltd email address.

Sample History

Where samples are submitted/analysed over several days, the last date of extraction is reported.

If the date and time of sampling are not provided, the Laboratory will not be responsible for compromised results should testing be performed outside the recommended holding time.

Description	Testing Site	Extracted	Holding Time
Ammonia (as N)	Melbourne	Sep 23, 2021	28 Days
- Method: APHA 4500-NH3 Ammonia Nitrogen by FIA			
Chloride	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-INO-4090 Chloride by Discrete Analyser			
Chromium (hexavalent)	Melbourne	Sep 23, 2021	28 Days
- Method: APHA 3500-Cr Hexavalent Chromium- (Extraction:- USEPA3060)			
Cyanide (amenable)	Melbourne	Sep 23, 2021	14 Days
- Method: Cyanide (Amenable) :- as per APHA 45 CN-G			
Cyanide (total)	Melbourne	Sep 23, 2021	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Fluoride (Total)	Melbourne	Sep 25, 2021	28 Days
- Method: LTM-INO-4150 Determination of Total Fluoride PART B – ISE			
Iodide	Sydney	Sep 24, 2021	28 Days
- Method: In-house method LTM-INO-4270 Anions by Ion Chromatography			
Nitrate (as N)	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Nitrite (as N)	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Organic Matter %	Melbourne	Sep 27, 2021	5 Days
- Method: APHA 2540E Fixed and Volatile Solids Ignited at 550C			
pH (units)(1:5 soil:CaCl2 extract at 25°C as rec.)	Melbourne	Sep 23, 2021	7 Days
- Method: LTM-GEN-7090 pH in soil by ISE			
Sulphate (as SO4)	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-INO-4110 Sulfate by Discrete Analyser			
Total Organic Carbon	Melbourne	Sep 25, 2021	28 Days
- Method: LTM-INO-4060 Total Organic Carbon in water and soil			
Total Soluble Salts*	Perth	Sep 21, 2021	0 Day
- Method: APHA 2540			
Phosphorus	Melbourne	Sep 23, 2021	180 Days
- Method: LTM-MET-3010 Alkali Metals Sulfur Silicon and Phosphorus by ICP-AES			
Acid Neutralising Capacity (ANCbt)	Brisbane	Sep 27, 2021	0 Days
- Method: Acid Neutralising Capacity (Acid reacted and Back-Titration) - Method 19A2			
Heavy Metals	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-MET-3040 Metals in Waters, Soils & Sediments by ICP-MS			
Alkali Metals	Melbourne	Sep 23, 2021	180 Days
- Method: LTM-MET-3010 Alkali Metals Sulfur Silicon Phosphorus by ICP-AES			
Conductivity (1:5 aqueous extract at 25°C as rec.)	Melbourne	Sep 23, 2021	7 Days
- Method: LTM-INO-4030 Conductivity			
Cation Exchange Capacity	Melbourne	Sep 25, 2021	180 Days
- Method: LTM-MET-3060 Cation Exchange Capacity by bases & Exchangeable Sodium Percentage			
Total Nitrogen Set (as N)			
Nitrate & Nitrite (as N)	Melbourne	Sep 23, 2021	28 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Total Kjeldahl Nitrogen (as N)	Melbourne	Sep 23, 2021	28 Days
- Method: APHA 4500-Norg B,D Total Kjeldahl Nitrogen by FIA			
% Moisture	Melbourne	Sep 21, 2021	14 Days
- Method: LTM-GEN-7080 Moisture

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer, that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
ug/L: micrograms per litre
ppm: Parts per million
ppb: Parts per billion
%: Percentage
org/100mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100mL: Most Probable Number of organisms per 100 millilitres

Terms

Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
LOR	Limit of Reporting.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
LCS	Laboratory Control Sample - reported as percent recovery.
CRM	Certified Reference Material - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
USEPA	United States Environmental Protection Agency
APHA	American Public Health Association
TCLP	Toxicity Characteristic Leaching Procedure
COC	Chain of Custody
SRA	Sample Receipt Advice
QSM	US Department of Defense Quality Systems Manual Version
CP	Client Parent - QC was performed on samples pertaining to this report
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
TEQ	Toxic Equivalency Quotient
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR : No Limit

Results between 10-20 times the LOR : RPD must lie between 0-50%

Results >20 times the LOR : RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% Phenols & 50-150% PFASs..

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM where no positive PFAS results have been reported have been reviewed and no data was affected.

.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Quality Control Results

Test	Units	Result 1			Acceptance Limits	Pass Limits	Qualifying Code
Method Blank							
Ammonia (as N)	mg/kg	< 5			5	Pass	
Chloride	mg/kg	< 5			5	Pass

Comments

Sample Integrity

Custody Seals Intact (if used)	N/A
Attempt to Chill was evident	Yes
Sample correctly preserved	Yes
Appropriate sample containers have been used	Yes
Sample containers for volatile analysis received with minimal headspace	Yes
Samples received within HoldingTime	Yes
Some samples have been subcontracted	No

Qualifier Codes/Comments

Code	Description
Q08	The matrix spike recovery is outside of the recommended acceptance criteria. An acceptable recovery was obtained for the laboratory control sample indicating a sample matrix interference.
Q15	The RPD reported passes Eurofins Environment Testing's QC - Acceptance Criteria as defined in the Internal Quality Control Review and Glossary page of this report.

Specimen description (Based on visual and tactile assessment)	(CL) Sandy CLAY, low plasticity, orange- grey, fine to coarse sand, trace fine gravel	**Sampling co-ordinates** Easting (m)	Northing (m)	**Reduced Level**

TEST REPORT - SUMMARY OF ANALYSIS

Visual reference

Date sampled:	**Unknown - tested as rcvd.**
Date tested:	27/09/21
Temperature (°C):	19.2°
Type of water used:	Distilled

Observations / Notes

Reaction with $BaCl_2$ indicates presence of gypsum

Emerson class number

Class 4

Emerson Class:	Definition / Notes
Class 1	*Air-dried crumbs of soil show a strong dispersing reaction, i.e., a colloidal cloud covers nearly the whole of the bottom of the beaker, usually in a very thin layer. The reaction should be evident within 10 minutes. In extreme cases all the water in the beaker becomes cloudy, leaving only a coarse residue in a cloud of clay.*
Class 2	*Air-dried crumbs of soil show a moderate to slight reaction. A moderate reaction consists of an easily recognizable cloud of colloids in suspension, usually spreading in thin streaks on the bottom of the beaker. A slight reaction consists of the bare hint of cloud in water at the surface of the crumbs.*
Class 3	*The soil remoulded at the plastic limit disperses in water.*
Class 4	*The remoulded soil does not disperse in water. Calcium carbonate (calcite) or calcium sulfate (gypsum) is present.*
Class 5	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension remains dispersed after 10 minutes.*
Class 6	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension begins to floculate within 10 minutes.*
Class 7	*The air-dried crumbs of soil remain coherent in water and swell.*
Class 8	*The air-dried crumbs of soil remain coherent in water and do not swell.*

Date sampled:	**Unknown - tested as rcvd.**
Date tested:	05/10/21
Temperature (°C):	20.0°
Type of water used:	Distilled

Observations / Notes

Reaction with BaCl2 indicates presence of gypsum

Emerson class number
Class 4

Emerson Class:	**Definition / Notes**
Class 1	*Air-dried crumbs of soil show a strong dispersing reaction, i.e., a colloidal cloud covers nearly the whole of the bottom of the beaker, usually in a very thin layer. The reaction should be evident within 10 minutes. In extreme cases all the water in the beaker becomes cloudy, leaving only a coarse residue in a cloud of clay.*
Class 2	*Air-dried crumbs of soil show a moderate to slight reaction. A moderate reaction consists of an easily recognizable cloud of colloids in suspension, usually spreading in thin streaks on the bottom of the beaker. A slight reaction consists of the bare hint of cloud in water at the surface of the crumbs.*
Class 3	*The soil remoulded at the plastic limit disperses in water.*
Class 4	*The remoulded soil does not disperse in water. Calcium carbonate (calcite) or calcium sulfate (gypsum) is present.*
Class 5	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension remains dispersed after 10 minutes.*
Class 6	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension begins to floculate within 10 minutes.*
Class 7	*The air-dried crumbs of soil remain coherent in water and swell.*
Class 8	*The air-dried crumbs of soil remain coherent in water and do not swell.*

Project ID:	**1772660-038-002**	**Lab report ref.:**	LMEL_21071988	
Project name:	Alcoa Anglesea	**Exploratory Hole**	**ANG-21-0207**	**Sample depth (m):** 0.00 - 0.00 **Client sample ref:**
Project reference:	Aloca Anglesea	**Loc. ref.:**	-	

Specimen description (Based on visual and tactile assessment)	(CI) Sandy CLAY, medium plasticity, dark brown/pale grey, fine to coarse grained sand, with fine grained gravel	**Sampling co-ordinates** Easting (m)	Northing (m)	**Reduced Level**

TEST REPORT - SUMMARY OF ANALYSIS

Visual reference

Date sampled:	**Unknown - tested as rcvd.**
Date tested:	05/10/21
Temperature (°C):	20.0°
Type of water used:	Distilled

Observations / Notes

Reaction with HCl indicates presence of calcites

Emerson class number

Class 4

Emerson Class:	Definition / Notes
Class 1	*Air-dried crumbs of soil show a strong dispersing reaction, i.e., a colloidal cloud covers nearly the whole of the bottom of the beaker, usually in a very thin layer. The reaction should be evident within 10 minutes. In extreme cases all the water in the beaker becomes cloudy, leaving only a coarse residue in a cloud of clay.*
Class 2	*Air-dried crumbs of soil show a moderate to slight reaction. A moderate reaction consists of an easily recognizable cloud of colloids in suspension, usually spreading in thin streaks on the bottom of the beaker. A slight reaction consists of the bare hint of cloud in water at the surface of the crumbs.*
Class 3	*The soil remoulded at the plastic limit disperses in water.*
Class 4	*The remoulded soil does not disperse in water. Calcium carbonate (calcite) or calcium sulfate (gypsum) is present.*
Class 5	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension remains dispersed after 10 minutes.*
Class 6	*The remoulded soil does not disperse in water and the 1:5 soil/water suspension begins to floculate within 10 minutes.*
Class 7	*The air-dried crumbs of soil remain coherent in water and swell.*
Class 8	*The air-dried crumbs of soil remain coherent in water and do not swell.*

Permeability test details

Permeant used:	Distilled water
Method of saturation:	Back pressure saturation
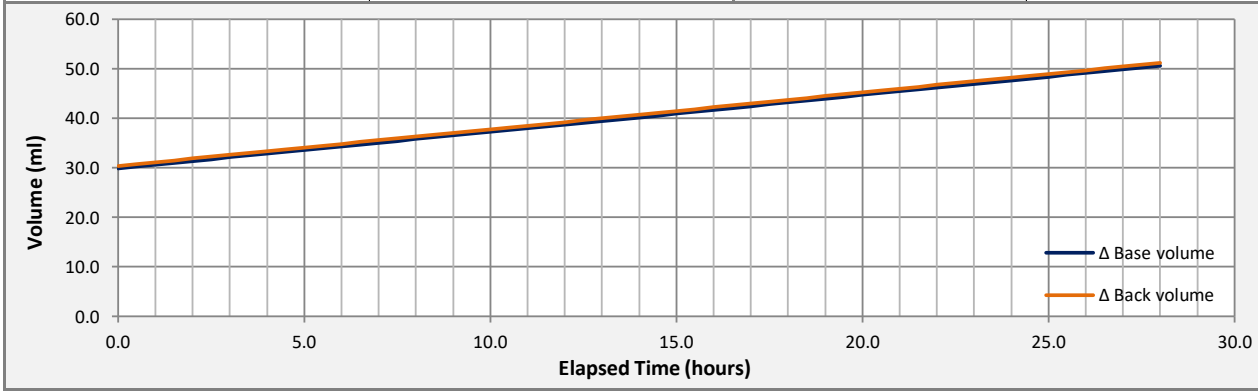
Estimate of initial saturation:	82.2%
Saturation B value:	99%
Confining Pressure (kPa):	1050
Inlet Pressure (kPa):	1010
Outlet Pressure (kPa):	990
Mean effective stress (kPa):	50
Hydraulic Head (kPa):	20
Moisture content after test:	27.9%
Permeability: (m/s)	**2E-09**



Notes: Specimen prepared from a u63 tube sample, provided by client

General Comments

- This report contains the following information:
  - Sample Container(s)/Preservation Non-Compliances
  - Summary of Sample(s) and Requested Analysis
  - Proactive Holding Time Report
  - Requested Deliverables
- **Please direct any queries related to sample condition / numbering / breakages to Client Services.**
- Sample Disposal - Aqueous (3 weeks), Solid (2 months) from receipt of samples.
- **Analytical work for this work order will be conducted at ALS Springvale.**
- **Please refer to the Proactive Holding Time Report table below which summarises breaches of recommended holding times that have occurred prior to samples/instructions being received at the laboratory. The laboratory will process these samples unless instructions are received from you indicating you do not wish to proceed. The absence of this summary table indicates that all samples have been received within the recommended holding times for the analysis requested.**
- Please be aware that APHA/NEPM recommends water and soil samples be chilled to less than or equal to 6°C for chemical analysis, and less than or equal to 10°C but unfrozen for Microbiological analysis. Where samples are received above this temperature, it should be taken into consideration when interpreting results. Refer to ALS EnviroMail 85 for ALS recommendations of the best practice for chilling samples after sampling and for maintaining a cool temperature during transit.

Sample Container(s)/Preservation Non-Compliances

All comparisons are made against pretreatment/preservation AS, APHA, USEPA standards.

- **No sample container / preservation non-compliance exists.**

Summary of Sample(s) and Requested Analysis

Some items described below may be part of a laboratory process necessary for the execution of client requested tasks. Packages may contain additional analyses, such as the determination of moisture content and preparation tasks, that are included in the package.
If no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component

No. of samples received	: 22		
No. of samples analysed	: 14		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Laboratory Coordinator	Melbourne Inorganics, Springvale, VIC
Eric Chau	Metals Team Leader	Melbourne Inorganics, Springvale, VIC
Jarwis Nheu	Senior Inorganic Chemist	Melbourne Inorganics, Springvale, VIC
Nikki Stepniewski	Senior Inorganic Instrument Chemist	Melbourne Inorganics, Springvale, VIC

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ED037 (Alkalinity): NATA accreditation does not cover the performance of this service.
- ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
- Amendment (13/7/22):This report has been amended to remove leachable TDS results which may not be indicative due to leaching solution involved with leach method
- ED045G: The presence of Thiocyanate, Thiosulfate and Sulfite can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).
- EN60: Where leachable PFAS analysis is requested, centrifugation rather than pressure filtration is used as the default approach for removal of particulates, in line with AS 4439.3.
- EN60-DI: Where leachable PFAS analysis is requested, centrifugation rather than pressure filtration is used as the default approach for removal of particulates, in line with AS 4439.3.

C-O-C number	: ----	Issue Date	: 13-Jul-2022
Sampler	: ANDREW MINARD, CLARE HOGAN		
Site	: Anglesea		
Quote number	: ME/260/22 V3		
No. of samples received	: 22		
No. of samples analysed	: 14		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Laboratory Coordinator	Melbourne Inorganics, Springvale, VIC
Eric Chau	Metals Team Leader	Melbourne Inorganics, Springvale, VIC
Jarwis Nheu	Senior Inorganic Chemist	Melbourne Inorganics, Springvale, VIC
Nikki Stepniewski	Senior Inorganic Instrument Chemist	Melbourne Inorganics, Springvale, VIC

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Sub-Matrix: **SOIL**

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

ALS Environmental

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **EM2212813**	Page	: 1 of 15
Amendment	: **1**		
Client	: **ALCOA Australia**	Laboratory	: Environmental Division Melbourne
Contact	: REBECCA FRASER	Telephone	: +6138549 9645
Project	: Anglesea Ash Risk Assessment C03568	Date Samples Received	: 04-Jul-2022
Site	: Anglesea	Issue Date	: 13-Jul-2022
Sampler	: ANDREW MINARD, CLARE HOGAN	No. of samples received	: 22
Order number	: ----	No. of samples analysed	: 14

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Duplicate outliers occur.**
- **NO Laboratory Control outliers occur.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **NO Quality Control Sample Frequency Outliers exist.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification
Analytical Methods	*Method*	*QC*	*Regular*	***Actual***	***Expected***	*Evaluation*

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001	SOIL	In house: Referenced to Rayment and Lyons 4B3 (mod.) or 4B4 (mod.) 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
pH (1:5) on 40°C dried soil	EA002-AD	SOIL	In house: Referenced to Rayment and Lyons 4A1 and APHA 4500H+. pH is determined on 40°C dried soil after a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3)
pH by Auto Titrator	EA005-P	SOIL	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM Schedule B(3)
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Electrical Conductivity (1:5) on 40°C dried soil	EA010-AD	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples dried at 40°C using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Conductivity by Auto Titrator	EA010-P	SOIL	In house: Referenced to APHA 2510 B. This procedure determines conductivity by automated ISE. This method is compliant with NEPM Schedule B(3)
Total Soluble Salts	EA014	SOIL	In house: The concentration of Total Soluble Salts in a soil is calculated from the Electrical conductivity of a water extract. This method is compliant with NEPM Schedule B(3).
Moisture Content	EA055	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 105-110 degrees C. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations on Alkaline Soils	* ED006	SOIL	In house: Referenced to Soil Survey Test Method C5. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with alcoholic ammonium chloride at pH 8.5. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil.
Exchangeable Cations	ED007	SOIL	In house: Referenced to Rayment & Lyons Method 15A1. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations with pre-treatment	ED008	SOIL	In house: Referenced to Rayment & Lyons Method 15A2. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Alkalinity in Soil	ED037	SOIL	In house: Referenced to APHA 2320 B Alkalinity is determined and reported on a 1:5 soil/water leach.
Alkalinity by Auto Titrator	ED037-P	SOIL	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)
Sulfate - Calcium Phosphate Soluble	ED040N	SOIL	In house: The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulfate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).

Analytical Methods	Method	Matrix	Method Descriptions
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	SOIL	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	SOIL	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride. In the presence of ferric ions the liberated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm.
Leachable Major Cations	ED093C	SOIL	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations in leachates are determined by either ICP-AES or ICP-MS techniques.
Cations - soluble by ICP-AES	ED093S	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010 (ICPAES) Water extracts of the soil are analyzed for major cations by ICPAES. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3).
Water Leachable Major Cations	ED093W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010; ALS QWI-EN/EG005, QWI-EN/ED093. The ICPAES technique quickly breaks the sample down into atoms and ions under extremely hot plasma. Atoms are then ionised, emitting a characteristic spectrum. The spectrometer then separates the wavelengths, prior to comparison of intensities against matrix matched standards for quantification.
Leachable Metals by ICPAES	EG005C	SOIL	In house: referenced to APHA 3120; USEPA SW 846 - 6010: The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Water Leachable Metals by ICPAES	EG005W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Leachable Mercury by FIMS	EG035C	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Total Mercury by FIMS	EG035T	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2) (Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. Mercury in solids are determined following an appropriate acid digestion. Ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Water Leachable Mercury by FIMS	EG035W	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Fluoride by Auto Titrator	EK040P	SOIL	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Total Fluoride	EK040T	SOIL	(In-house) Total fluoride is determined by ion specific electrode (ISE) in a solution obtained after a Sodium Carbonate / Potassium Carbonate fusion dissolution.

Preparation Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001-PR	SOIL	In house: Referenced to Rayment and Lyons 4B1, 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations Preparation Method (Alkaline Soils)	ED006PR	SOIL	In house: Referenced to Rayment and Lyons method 15C1.
Exchangeable Cations Preparation Method	ED007PR	SOIL	In house: Referenced to Rayment & Lyons method 15A1. A 1M NH4Cl extraction by end over end tumbling at a ratio of 1:20. There is no pretreatment for soluble salts. Extracts can be run by ICP for cations.
Calcium Phosphate Extraction for Sulphate as SO4 2-	ED040NPR	SOIL	The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulphate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).
Total Fluoride	EK040T-PR	SOIL	In house: Samples are fused with Sodium Carbonate / Potassium Carbonate flux.
Digestion for Total Recoverable Metals in TCLP Leachate	EN25C	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
Digestion for Total Recoverable Metals in DI Water Leachate	EN25W	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
1:5 solid / water leach following drying at 40°C	EN34-AD	SOIL	10 g of 40°C dried soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes - Plastic Leaching Vessel	EN60a-P	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates.
Deionised Water Leach - Plastic Leaching Vessel	EN60-DIa-P	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates

Preparation Methods	Method	Matrix	Method Descriptions
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ED037 (Alkalinity): NATA accreditation does not cover the performance of this service.
- ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
- EG035W: EM2221404#8 Poor matrix spike recovery for water leachable mercury due to sample matrix. Confirmed by re-extraction and re-analysis.
- EN60-DIa-G: EM2221404 Due to limited sample for leach analysis, a scaled down amount of 50g into 1000mL was used for samples #1/7 & 6/12.
- ED045G: The presence of Thiocyanate, Thiosulfate and Sulfite can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).

ALS Environmental

QUALITY CONTROL REPORT

Work Order	: **EM2221404**	Page	: 1 of 12
Client	: **ALCOA Australia**	Laboratory	: Environmental Division Melbourne
Contact	: REBECCA FRASER	Contact	: Peter Ravlic
Address	: POINT HENRY WORKS P.O.BOX 460 GEELONG VIC, AUSTRALIA 3220	Address	: 4 Westall Rd Springvale VIC Australia 3171
Telephone	: ----	Telephone	: +6138549 9645
Project	: Anglesea Ash Risk Assessment C03568	Date Samples Received	: 04-Jul-2022
Order number	: 7293974	Date Analysis Commenced	: 02-Nov-2022
C-O-C number	: ----	Issue Date	: 07-Nov-2022
Sampler	: ANDREW MINARD, CLARE HOGAN		
Site	: Anglesea		
Quote number	: ME/260/22 V3		
No. of samples received	: 12		
No. of samples analysed	: 12		

Accreditation No. 825
Accredited for compliance with ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Dilani Fernando	Laboratory Coordinator	Melbourne Inorganics, Springvale, VIC
Eric Chau	Metals Team Leader	Melbourne Inorganics, Springvale, VIC

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

Sub-Matrix: **SOIL**

ALS Environmental

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **EM2221404**	Page	: 1 of 16
Client	: **ALCOA Australia**	Laboratory	: Environmental Division Melbourne
Contact	: REBECCA FRASER	Telephone	: +6138549 9645
Project	: Anglesea Ash Risk Assessment C03568	Date Samples Received	: 04-Jul-2022
Site	: Anglesea	Issue Date	: 07-Nov-2022
Sampler	: ANDREW MINARD, CLARE HOGAN	No. of samples received	: 12
Order number	: 7293974	No. of samples analysed	: 12

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Duplicate outliers occur.**
- **NO Laboratory Control outliers occur.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **NO Quality Control Sample Frequency Outliers exist.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001	SOIL	In house: Referenced to Rayment and Lyons 4B3 (mod.) or 4B4 (mod.) 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
pH (1:5) on 40°C dried soil	EA002-AD	SOIL	In house: Referenced to Rayment and Lyons 4A1 and APHA 4500H+. pH is determined on 40°C dried soil after a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3)
pH by Auto Titrator	EA005-P	SOIL	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM Schedule B(3)
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Electrical Conductivity (1:5) on 40°C dried soil	EA010-AD	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples dried at 40°C using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Conductivity by Auto Titrator	EA010-P	SOIL	In house: Referenced to APHA 2510 B. This procedure determines conductivity by automated ISE. This method is compliant with NEPM Schedule B(3)
Total Soluble Salts	EA014	SOIL	In house: The concentration of Total Soluble Salts in a soil is calculated from the Electrical conductivity of a water extract. This method is compliant with NEPM Schedule B(3).
Moisture Content	EA055	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 105-110 degrees C. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations on Alkaline Soils	* ED006	SOIL	In house: Referenced to Soil Survey Test Method C5. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with alcoholic ammonium chloride at pH 8.5. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil.
Exchangeable Cations	ED007	SOIL	In house: Referenced to Rayment & Lyons Method 15A1. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations with pre-treatment	ED008	SOIL	In house: Referenced to Rayment & Lyons Method 15A2. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Alkalinity in Soil	ED037	SOIL	In house: Referenced to APHA 2320 B Alkalinity is determined and reported on a 1:5 soil/water leach.
Alkalinity by Auto Titrator	ED037-P	SOIL	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)
Sulfate - Calcium Phosphate Soluble	ED040N	SOIL	In house: The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulfate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).

Analytical Methods	Method	Matrix	Method Descriptions
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	SOIL	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	SOIL	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride. In the presence of ferric ions the liberated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm.
Leachable Major Cations	ED093C	SOIL	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations in leachates are determined by either ICP-AES or ICP-MS techniques.
Cations - soluble by ICP-AES	ED093S	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010 (ICPAES) Water extracts of the soil are analyzed for major cations by ICPAES. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3).
Water Leachable Major Cations	ED093W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010; ALS QWI-EN/EG005, QWI-EN/ED093. The ICPAES technique quickly breaks the sample down into atoms and ions under extremely hot plasma. Atoms are then ionised, emitting a characteristic spectrum. The spectrometer then separates the wavelengths, prior to comparison of intensities against matrix matched standards for quantification.
Leachable Metals by ICPAES	EG005C	SOIL	In house: referenced to APHA 3120; USEPA SW 846 - 6010: The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Water Leachable Metals by ICPAES	EG005W	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Leachable Mercury by FIMS	EG035C	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Total Mercury by FIMS	EG035T	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2) (Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. Mercury in solids are determined following an appropriate acid digestion. Ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Water Leachable Mercury by FIMS	EG035W	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Fluoride by Auto Titrator	EK040P	SOIL	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Total Fluoride	EK040T	SOIL	(In-house) Total fluoride is determined by ion specific electrode (ISE) in a solution obtained after a Sodium Carbonate / Potassium Carbonate fusion dissolution.

Preparation Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001-PR	SOIL	In house: Referenced to Rayment and Lyons 4B1, 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations Preparation Method (Alkaline Soils)	ED006PR	SOIL	In house: Referenced to Rayment and Lyons method 15C1.
Exchangeable Cations Preparation Method	ED007PR	SOIL	In house: Referenced to Rayment & Lyons method 15A1. A 1M NH4Cl extraction by end over end tumbling at a ratio of 1:20. There is no pretreatment for soluble salts. Extracts can be run by ICP for cations.
Calcium Phosphate Extraction for Sulphate as SO4 2-	ED040NPR	SOIL	The sample is extracted with a calcium phosphate solution. The phosphate ion displaces the adsorbed sulphate while calcium ions depress the extraction of interfering S from soil organic matter. SO4 in the extract is determined by ICPAES and reported as dry weight in the original soil. This method is compliant with NEPM Schedule B(3).
Total Fluoride	EK040T-PR	SOIL	In house: Samples are fused with Sodium Carbonate / Potassium Carbonate flux.
Digestion for Total Recoverable Metals in TCLP Leachate	EN25C	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
Digestion for Total Recoverable Metals in DI Water Leachate	EN25W	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
1:5 solid / water leach following drying at 40°C	EN34-AD	SOIL	10 g of 40°C dried soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes - Glass Leaching Vessel	EN60a-G	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
Deionised Water Leach - Glass Leaching Vessel	EN60-DIa-G	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates

Preparation Methods	Method	Matrix	Method Descriptions
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).

Eurofins reference	903790

Sample Information

✓	A detailed list of analytes logged into our LIMS, is included in the attached summary table.
✓	All samples have been received as described on the above COC.
✓	COC has been completed correctly.
✓	Attempt to chill was evident.
✓	Appropriately preserved sample containers have been used.
✓	All samples were received in good condition.
✗	Samples have been provided with adequate time to commence analysis in accordance with the relevant holding times.
✓	Appropriate sample containers have been used.
✓	Sample containers for volatile analysis received with zero headspace.
✗	Split sample sent to requested external lab.
✗	Some samples have been subcontracted.
N/A	Custody Seals intact (if used).

Notes

Contact

If you have any questions with respect to these samples, please contact your Analytical Services Manager:

Michael Morrison on phone : 03 8564 5933 or by email: MichaelMorrison@eurofins.com

Results will be delivered electronically via email to Rebecca Fraser - rebecca.fraser@ehs-support.com.

Note: A copy of these results will also be delivered to the general EHS Support Pty Ltd email address.

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
µg/L: micrograms per litre
ppm: parts per million
ppb: parts per billion
%: Percentage
org/100 mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100 mL: Most Probable Number of organisms per 100 millilitres

Terms

APHA	American Public Health Association
COC	Chain of Custody
CP	Client Parent - QC was performed on samples pertaining to this report
CRM	Certified Reference Material (ISO17034) - reported as percent recovery.
Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
LOR	Limit of Reporting.
LCS	Laboratory Control Sample - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
SRA	Sample Receipt Advice
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
TBTO	Tributyltin oxide (*bis*-tributyltin oxide) - individual tributyltin compounds cannot be identified separately in the environment however free tributyltin was measured and its values were converted stoichiometrically into tributyltin oxide for comparison with regulatory limits.
TCLP	Toxicity Characteristic Leaching Procedure
TEQ	Toxic Equivalency Quotient or Total Equivalence
QSM	US Department of Defense Quality Systems Manual Version 5.4
US EPA	United States Environmental Protection Agency
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR: No Limit

Results between 10-20 times the LOR: RPD must lie between 0-50%

Results >20 times the LOR : RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% for Speciated Phenols & 50-150% for PFAS

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM 5.4 where no positive PFAS results have been reported have been reviewed and no data was affected.

.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Sample History

Where samples are submitted/analysed over several days, the last date of extraction is reported.

If the date and time of sampling are not provided, the Laboratory will not be responsible for compromised results should testing be performed outside the recommended holding time.

Description	Testing Site	Extracted	Holding Time
Eurofins Suite B11E: Cl/SO4/Alkalinity			
Chloride (1:5 aqueous extract)	Melbourne	Jul 07, 2022	28 Days
- Method: LTM-INO-4090 Chloride by Discrete Analyser			
Sulphate as SO4 (1:5 aqueous extract)	Melbourne	Jul 07, 2022	28 Days
- Method: LTM-INO-4110 Sulfate by Discrete Analyser (1:5 extract)			
Alkalinity (speciated)	Melbourne	Jul 07, 2022	14 Days
- Method: LTM-INO-4250 Alkalinity by Electrometric Titration			
Conductivity (1:5 aqueous extract at 25 °C as rec.)	Melbourne	Jul 07, 2022	7 Days
- Method: LTM-INO-4030 Conductivity

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
µg/L: micrograms per litre
ppm: parts per million
ppb: parts per billion
%: Percentage
org/100 mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100 mL: Most Probable Number of organisms per 100 millilitres

Terms

APHA	American Public Health Association
COC	Chain of Custody
CP	Client Parent - QC was performed on samples pertaining to this report
CRM	Certified Reference Material (ISO17034) - reported as percent recovery.
Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
LOR	Limit of Reporting.
LCS	Laboratory Control Sample - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
SRA	Sample Receipt Advice
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
TBTO	Tributyltin oxide (*bis*-tributyltin oxide) - individual tributyltin compounds cannot be identified separately in the environment however free tributyltin was measured and its values were converted stoichiometrically into tributyltin oxide for comparison with regulatory limits.
TCLP	Toxicity Characteristic Leaching Procedure
TEQ	Toxic Equivalency Quotient or Total Equivalence
QSM	US Department of Defense Quality Systems Manual Version 5.4
US EPA	United States Environmental Protection Agency
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR: No Limit

Results between 10-20 times the LOR: RPD must lie between 0-50%

Results >20 times the LOR : RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% for Speciated Phenols & 50-150% for PFAS

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM 5.4 where no positive PFAS results have been reported have been reviewed and no data was affected.

.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Quality Control Results

Comments

Sample Integrity

Custody Seals Intact (if used)	N/A
Attempt to Chill was evident	Yes
Sample correctly preserved	Yes
Appropriate sample containers have been used	Yes
Sample containers for volatile analysis received with minimal headspace	Yes
Samples received within HoldingTime	N/A
Some samples have been subcontracted	No

Qualifier Codes/Comments

Code	Description
I12	Where sampling date has not been provided, Eurofins | Environment Testing is not able to determine whether analysis has been performed within recommended holding times.
Q15	The RPD reported passes Eurofins Environment Testing's QC - Acceptance Criteria as defined in the Internal Quality Control Review and Glossary page of this report.

RPD Calculations for Quality Check Samples

Project Name: Anglesea Ash Risk Assessment Site Investigation July 2022
Client: Alcoa
Project Number: AUS_C03568
EPA Number: N/A
Site Address: Coalmine Road, Anglesea Victoria
Project Manager: Rebecca Fraser

AS 4482.1-2005 *Guide to the Investigation and Sampling of Sites with Potentially Contaminated Soil- Non-volatile and Semi-volatile Compounds* (Standards Australia, 2005) states that the typical RPD which can be expected from acceptable field duplicates is < ± 30-50% of the mean concentration of the analyte, where the results are greater than ten times the limit of reporting (LOR).

Analyte	Units	LOR (ALS)	ALS analysis ANG-21-0202	Eurofins analysis ANG-21-0210 FS of 202	Primary & triplicate RPD %
Sample date			14/09/2021	14/09/2021	
% Moisture	%	1	21.1	20	5%
Acid Neutralising Capacity (ANCbt)	% CaCO3	0.1	1.3	1.3	0%
Ammonia (as N)	mg/kg	20	<20	5.5	114%
Chloride	mg/kg	10	240	200	18%
Chromium (hexavalent)	mg/kg	0.5	<0.5	< 1	0%
Conductivity (1:5 aqueous extract at 25°C as rec.)	mg/kg	1	1940	1200	47%
Cyanide (amenable)	mg/kg	0.5	<1	< 5	0%
Cyanide (total)	mg/kg	1	<1	< 5	0%
Fluoride (Total)	mg/kg	40	90	< 100	11%
Iodide	mg/kg	0.05	<0.5	< 5	0%

Environmental Quality Control Check

Project Details:

PROJECT: Anglesea Ash Risk Assessment Site Investigation September 2021
CLIENT: ALCOA
PROJECT NUMBER: AUS_C03568
EPA NUMBER: N/A
SITE ADDRESS: COALMINE ROAD, ANGLESEA VICTORIA
PROJECT MANAGER: REBECCA FRASER
REPORT REVIEWED:
ALS EM2118436 September 2021
Eurofins 826015 September 2021

Fieldworks Conducted:

- **2021 September soil sampling within the consolidated ash area**
- **Ten primary and 1 triplicate samples collected for totals and leachable fraction (pH2.9 and deionised water) analysis**

Laboratories Used:

PRIMARY: ALS
SECONDARY: Eurofins

Laboratory Batch Numbers:

PRIMARY: ALS EM2118436 September 2021
SECONDARY: Eurofins 826015 September 2021

Data Quality Objectives:

- Preserve, store and transport soil samples so that sample integrity is not compromised
- The minimum number of sample duplicates and triplicates are collected and analysed
- Relative percentage differences (RPDs) between field sample, duplicates and triplicates within acceptable range
- Laboratory analyses meet internal laboratory quality control procedures

1.0 Soil Sampling

	Yes	No	Comment
1. Was the soil sampling methodology adequate?	☒	☐	
2. Were soil bore samples collected directly from push tubes?	☒	☐	
3. Were the soil sampling locations adequate?	☒	☐	
4. Does the sample density confirm to Australian Standard 4482.1?	☒	☐	AS4482.1 not relevant for this sampling event as the objective for sampling and analysis was to sample and analyse clay-rich cover and consolidated ash
5. Were samples composited?	☐	☒	
6. Were samples adequately selected for analysis based on field observations?	☒	☐	Sample selection based on mbgl and known extent of clay-rich cover and consolidated ash
7. Were samples selected for analysis from adequate depth ranges?	☒	☐	Where field conditions allowed and up to 9.4 mbgl
8. Were samples analysed for adequate analytical suites?	☒	☐	Analytes were selected based on indicator analytes in ash and a comprehensive suite including nutrients and cation exchange capacity
9. Were appropriate decontamination procedures used?	☒	☐	Nitrile gloves were used and replaced for each sample location
10. Were equipment calibration records provided?	☒	☐	n/a
11. Were sample locations clearly marked on a plan or collected by GPS?	☒	☐	
12. Were soil samples compared against relevant criteria	☐	☒	n/a
13. Where relevant, did soil sampling comply with the relevant SAQP?	☐	☒	SAQP not developed for this sampling event

Comments:

None

Soil sampling was:

☒ Satisfactory ☐ Partially Satisfactory ☐ Unsatisfactory

2.0 Field Quality Control - Soil

2.1 Soil QC Sample Summary:

	ALS	Eurofins
Laboratory Reference	EM2118436	826015
1. Number of days sampling	2	
2. Sampling Dates	13/09/2021 to 14/09/2021 inclusive	
3. Total Number of primary samples analysed	10	-
4. Number of Rinsate Blanks	-	-
5. Number of Field Blanks	-	-
6. Number of Trip Blanks	-	-
7. Number of Field Duplicates (blind)	-	-
8. Number of Field Triplicates (split)	-	1

2.2 Soil Analytical Suites:

Soil - Totals

	Number of primary samples analysed	Number of duplicate samples analysed	Number of triplicate samples analysed
Metals[1]	10	-	1
Major ions[2]	10	-	1
Fluoride, iodide, cyanide	10	-	1
Nutrients[3]	10	-	1
CEC	10	-	1
pH, EC, TSS	10	-	1

Notes:

1- Metals – Al, Sb, As, Ba, Be, B, Cd, Cr, Co, Cu, Fe, Hg, Pb, Mn, Mo, Ni, Se, Zn
2- Major ions – Ca, Mg, Na, K, SO4, Cl,
3- Nutrients – ammonia, nitrite, nitrate, total kjeldahl nitrogen, phosphorus

Soil – Leachable Fraction

	Number of primary samples analysed	Number of duplicate samples analysed	Number of triplicate samples analysed
Metals[1]	10	-	1
Major ions[2]	10	-	1
Fluoride, iodide, cyanide	10	-	1
Nutrients[3]	10	-	1
CEC	10	-	1

	Number of primary samples analysed	Number of duplicate samples analysed	Number of triplicate samples analysed
pH, EC	10	-	1

Notes:

1- Metals – Al, Sb, As, Ba, Be, B, Cd, Cr, Co, Cu, Fe, Hg, Pb, Mn, Mo, Ni, Se, Zn
2- Major ions – Ca, Mg, Na, K, SO4, Cl
3- Nutrients – ammonia, nitrite, nitrate, total kjeldahl nitrogen, phosphorus

3.0 Precision and Sample Handling

	Yes	No	Comment
1. Were NATA registered laboratories used?	☒	☐	
2. Did the laboratory perform the requested tests?	☒	☐	
3. Were the laboratory methods adopted NATA endorsed?	☐	☒	ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
4. Were the laboratory reporting limits satisfactory?	☒	☐	
5. Was the NATA Seal on the reports?	☒	☐	
6. Were the reports signed by an authorised person?	☒	☐	
7. Were the samples in proper custody between the field and laboratory?	☒	☐	
8. Were the samples properly and adequately preserved?	☒	☐	
9. Were the samples received by the laboratory in good condition?	☒	☐	
10. Were the samples received by the laboratory chilled?	☒	☐	
11. Were samples analysed within the specified holding times?	☒	☐	

Comments:

None

Precision and sample handling was:

☒ Satisfactory ☐ Partially Satisfactory ☐ Unsatisfactory

3.1 Soil Field QC Assessment:

	Yes	No	Comment
1. Were an adequate number of blanks analysed?	No blanks collected or required		N/A
2. Were the analytical suites for the blank samples adequate?			
3. Were the blank sample results free of contamination?			
4. Were an adequate number of replicate samples analysed?	☒	☐	
5. Were the analytical suites for the replicate samples adequate?	☒	☐	
6. Were the replicate RPDs within acceptable limits?	☐	☒	Many of the results were reported below LOR
7. Were any elevated RPDs adequately explained?	☒	☐	Differences between laboratory LORs account for most elevated RPDs

Comments:

- Many of the RPDs were outside acceptable limits due to results being below the limit of reporting (LOR), and LORs differing between laboratory methods. RPDs greater than 50% were also reported on results which were less than 10 times the LOR. Remaining RPDs exceeding 50% do not affect the overall usability of the laboratory analytical results.

Field QC for soil was:

☒ Satisfactory ☐ Partially Satisfactory ☐ Unsatisfactory

4.0 Laboratory Internal Quality Control – Soil and Waters

	Primary Lab Batch: EM2212813	Secondary Lab Batch: 903790
1. Were all the laboratory method blanks free of contamination?	Yes	Only 1 sample analysed no QC provided
2. Number of the laboratory duplicate outliers?	2	
3. Number of the laboratory control sample (LCS) outliers?	0	
4. Number of the surrogate recovery outliers?	0	
3. Number of matrix spike (MS) outliers?	6	
4. Number of laboratory quality control sample frequency outliers?	5	

Comments:

Laboratory duplicate outliers exist for total kjeldahl nitrogen. Matrix spike recovery for soils less than lower data quality objective for hexavalent chromium and total organic carbon.
Matrix spike recovery level for waters not determined for iron and sulfate (as SO42-). Background level greater than or equal to the 4x spike level. Matrix spike recovery for water less than lower data quality objective for hexavalent chromium.
Laboratory quality control sample frequency outliers in waters for dissolved organic carbon and fluoride.
This is not expected to affect the validity of the results as acceptable recovers were achieved in the laboratory control sample analyses.

Laboratory Internal QC for soil and waters was:

☒ Satisfactory ☐ Partially Satisfactory ☐ Unsatisfactory

5.0 Data Usability

Following a detailed review of the field and laboratory Quality Control it is considered that the assessment has provided acceptable QA/QC results and the data of the sampling and analysis program are usable with the modifications detailed below.

QC Conclusion:

☐ Data is directly usable

☒ Data is usable noting the following comments

☐ Data is usable after the following modifications

☐ Data is not usable

Comments:

Many of the RPDs were outside acceptable limits due to results being below the LOR, and LORs differing between laboratory methods. RPDS greater than 50% were also reported on results which were less than 10 times the LOR. One laboratory outlier was reported, however EHS Support considers that the field duplicate and ALS quality assurance and quality control discrepancies do not affect the overall usability of the laboratory analytical results, given the overall Data Quality Objectives were met:

Data Quality Objective	Acceptance Criteria	Comments
Preserve, store and transport soil samples so that sample integrity is not compromised	Use esky seals where provided by laboratory Clearly fill in labels with project details Provide copy of the chain of custody (COC) in a waterproof bag Use ice to chill samples to 0 – 6 °C	Attempt to chill was evident for all samples. ALS reported temperature of 3.8 °C. Security seals reported intact by ALS Note: Triplicate sample forwarded by ALS to Eurofins
The minimum number of sample duplicates and triplicates are collected and analysed	Requirement of duplicate and triplicate collection of 1 in 20 samples.	Duplicate and triplicate sample collected at a rate above minimum requirements
Relative percentage differences (RPDs) between field sample, duplicates and triplicates within acceptable range	For results >10 times LOR the RPD between 30-50% of analyte mean concentration No RPD range applied for results <10 times the LOR	Many results were reported below the LOR The RPDs which exceed 50% do not affect the overall usability of the laboratory analytical results
Laboratory analyses meet internal laboratory quality control procedures	MS and LCS - Generally 70-130% for inorganics/metals Blanks - < LOR Duplicates – 5 times LOR 0-50% RPD is acceptable.	All ALS laboratory analyses met the quality control, with the exception of: Laboratory duplicate outliers exist for total kjeldahl nitrogen. Matrix spike recovery for soils less than lower data quality objective for hexavalent chromium and total organic carbon. Matrix spike recovery level for waters not determined for iron and sulfate (as SO42-). Background level greater than or equal to the 4x spike level. Matrix spike recovery for water less than lower data quality objective for hexavalent chromium. Laboratory quality control sample frequency outliers in waters for dissolved organic carbon and fluoride. This is not expected to affect the validity of the results as acceptable recovers were achieved in the laboratory control sample analyses.

TABLE OF CONTENTS

1.0 Introduction 7
1.1 Assessment Framework 8
1.1.1 Stage 1 - Sample collection and characterisation 8
1.1.2 Stage 2: Hydrogeologic Flux Assessment 8
1.1.3 Stage 3 - Geochemical transport simulations 8

2.0 Background 10
2.1 Historical Characterisation of Ash Materials 10
2.2 Hydrogeology and Pit water body Geochemistry 13
2.3 Background Surface Water Quality 14
2.4 Conceptual Exposure Model and Beneficial Uses 14

3.0 Stage One – Field Sample Collection and Characterisation 20
3.1 Field Sample Collection 20
3.2 Laboratory Analytical Results 21
3.2.1 Ash Solids 22
3.2.1.1 Physical Characteristics 22
3.2.1.2 Ash Acid and Alkaline Generating Characteristics 23
3.2.1.3 Major Ions 24
3.2.1.4 Metals, metalloids and minor anions 26
3.2.2 Ash Pond Solids – ASLP Results 27
3.2.2.1 Reagent Water 1 – Ash Pond 1 water 27
3.2.2.2 Reagent Water 2 – UEVF groundwater 28
3.2.3 Ash pond water and UEVF groundwater 31
3.2.3.1 Major Ions 31
3.2.3.2 Minor Ions 31
3.2.3.3 Nutrients 32
3.3 Assessment of ASLP and Pond Water Samples against Screening Criteria 35

4.0 Stage Two – Hydrogeologic Conceptualisation of fluxes 37
4.1 Inputs and Assumptions 38
4.1.1 Upward Gradient (Movement from UEVF to Pit water body) 38
4.1.2 Downward Gradient (Movement from Pit water body to UEVF) 38
4.2 Analytical Block Model Results 40
4.2.1 Upward Gradient (Movement from UEVF to Pit water body) 42
4.2.2 Downward Gradient (Movement from Pit water body to UEVF) 42
4.3 Numerical Modelling Results 43

5.0 Stage Three – Geochemical Transport Simulation 44
5.1 Development of the transport flow pathway 44
5.2 UEVF groundwater flow through Ash - Model Input 46
5.2.1 Transport Solutions 46
5.2.2 Transport Parameters 47
5.3 UEVF groundwater flow through Ash - Model Output 50
5.4 Pit water body flow through Ash - Model Input 56
5.4.1 Transport Solutions 56
5.4.2 Transport Parameters 56
5.5 Pit water body flow through Ash - Model Output 56
5.6 Defining Surface Water and Groundwater Concentrations using Transport Solutions 62
5.6.1 Pit water body as a receptor 62
5.6.2 UEVF groundwater as a receptor 63

Draft and Confidential

6.0 Conclusions 65

7.0 References 66

KEY TERMS OF REFERENCE

Stratification:

This report makes mention of lake or water body stratification. Where stratification is mentioned throughout the text, the following can be inferred: At different times of the year and/or under surface water flow regimes, the water body may experience "stratification" where three distinct layers occur throughout its vertical profile: Epilimnion: (top); Metalimnion: (middle); and Hypolimnion: (base). When a water body becomes stratified, generally the more anoxic, lower pH and higher dissolved metal concentrations are anticipated in deeper portions of the water body (the Metalimnion and Hypolimnion) with the upper layer (Epilimnion) experiencing higher alkalinity and pH. Further, rarely will a water body exhibit "stratification" all year around with various degrees of seasonal mixing, including complete mixing, occurring between the individual layers.

Alkaline Horizon:

Where the term "Alkaline horizon" is referenced, the following can be inferred. When a waterbody exhibits strong stratification, minimal mixing between the Metalimnion (middle of the water body) and Epilimnion (top of the water body) occurs. This results in higher alkalinity and pH water in the upper parts of the water body (Epilimnion).

1.0 INTRODUCTION

The long-term goal for the rehabilitation of the coal pit void is the creation of a pit water body. Extraction of groundwater in the vicinity of the pit void by Alcoa ceased in early 2016 and the rebound of groundwater levels will gradually flood the pit void. Groundwater and rainfall will contribute to the filling of the pit void which analytical solutions estimate will take greater than 20 years and empirical models indicate longer filling time. The slow filling of the pit void increases the risk of acidity generation from materials within the pit void such as overburden and spoil, the exposed unworked coal seams within the pit walls and ultimately the materials that will be disturbed and moved into the pit as the pit walls are stabilised.

As part of the phased decommissioning of the Alcoa Anglesea power station facility and the rehabilitation of the coal pit void, ash from the ash ponds was relocated from the Power Station site to a designated area of the coal pit void. Ash was produced from the burning of brown coal (mined from the adjacent coal pit) and was settle and stored within Ash Ponds 1. Approximately 1,500,000 tons of ash has been historically placed within the pit and the more recent 125,000 tonnes placed in the pit making up 8% of the total ash. Alcoa has a licence issued by Victoria EPA which permits them to dispose of ash into the mine (EPA Victoria, 2007). Ash which has been historically stored within ash pond one (1) on the power station site. The majority of ash has been relocated with some residual materials with ash pond 1 currently being excavated and transported to the pit. All ash management works will be completed in 2017.

The ash from the recent ash removal activity has been placed in the eastern portion of the coal mine pit (near the existing Ash Piles) in an area of approximately 7 hectares. Based on topographical information for the area, the ash will be placed at an elevation of between -15 m Australian Height Datum (AHD) and -10 m AHD. Alcoa dredged and pumped these materials to a designated location and is allowing these materials to dewater and naturally consolidate. Once the materials are dry Alcoa is planning to compact these materials and then place up to 1 m of overburden materials (comprising silts and clays) over the ash materials. While the ash materials provide a potential ameliorating effect on the acidity of the water body, low permeability materials will be placed over the ash to prevent dissolution of metals and further degradation of water quality. Silt and clay materials from the historical mining activities have historically been stockpiled on-site and in combination with soils in close proximity to the ash pit will be used as cover. These materials will be placed in lifts and compacted to provide a barrier between the developing lake and ash deposits and limit the flux in surface water or groundwater.

The hydrogeologic evaluations and geochemical simulations detailed within this report have been developed to assess the potential long-term impacts associated with the recent placement of Ash within the mine pit. The ash material will be encapsulated with clay spoil and the flux to groundwater is limited by the presence of a low permeability basal clay unit within the base of the pit. Similarly, the placement of cover materials over the ash will limit interactions within the water body. The assessment provided below was conducted using a staged approach including soil sampling and Ash Pond water sampling and analysis, preliminary screening of data and geochemical modelling. Based on these assessments the potential for impacts on groundwater and surface water quality is considered limited and water quality is anticipated to be consistent with background and/or the existing conditions within the pit water body.

Environmental monitoring will be conducted to verify and validate the findings of this assessment and in combination with the short-term alkaline additions and the establishment of natural processes within the pit water body it is anticipated that water quality will improve over time. Future environmental monitoring will include:

- pH, nutrient and dissolved metal loading of Salt Creek prior to discharge into the pit water body
- pH, nutrients and metal speciation and distribution (horizontally and vertically within the pit water body and outflows from the water body.

Draft and Confidential

Future sampling will assess the quality of the water body and discharge outflows against the SEPP and ANZECC criteria. This program of sampling is discussed further in the Water Monitoring, Management and Contingency Plan (**EHS Support 2017(c)**).

1.1 Assessment Framework

The assessment of ash has been conducted in a staged manner to provide multiple lines of evidence in the assessment of the ash properties and potential impacts on surface water and groundwater quality. This has included:

1.1.1 Stage 1 - Sample collection and characterisation

Sample collection and laboratory analysis of solid and aqueous samples completed between June 2016 and May 2017:

- Anthropogenic ash material from ash pond 1
- Ash pond water from ash pond 1
- Upper Eastern View Formation (UEVF) groundwater from Well bore 15
- Australian Standard Leachate Procedure (ASLP) analysis on interaction between ash solids and ash pond water and ash solids and UEVF groundwater.
- Pit water body quality

The sample results are evaluated against generic criteria and in particular the leach testing and pond water results are compared to relevant surface water and groundwater criteria to identify chemicals of potential concern (COPCs) and determine what Dilution Attenuation Factors (DAFs) would be required in the environment to achieve regulatory criteria.

Ash pond water and ASLP results from ash pond solids and ash pond reagent water were compared to observe whether the ash pond water was in equilibrium with the ash pond solids. This would support the selection of ash pond water quality as the ash pond pore water in the transport simulation experiments.

1.1.2 Stage 2: Hydrogeologic Flux Assessment

This assessment uses hydrogeologic data for the site to quantify the fluxes during mine closure from surface water to groundwater (after re-diversion of Salt Creek) and from groundwater to surface water after establishment of the lake. Using these fluxes, the DAF for the fluxes from the Ash management areas and the receiving water bodies to determine if potential ASLP and Ash Pond water sample analytical results could result in exceedances of criteria.

This assessment was in addition to the groundwater modelling which evaluated the nature of groundwater/surface water interactions and advective transport of recharged surface water away from the pit void.

1.1.3 Stage 3 - Geochemical transport simulations

Geochemical transport simulations were used to look at the potentially chemical influences the ash solids in the base of the pit have on porewater. The porewater could represent UEVF groundwater flowing under a discharge scenario from the UEVF aquifer into the pit water body. Porewater could also comprise pit water body which could recharge through the ash material and into the UEVF aquifer. The aqueous and leachable analyses collected during Stage 1 were to be used in PHREEQC transport scenarios between the following solutions and solids using the hydrogeologic properties and DAF developed in Stage 2.

Draft and Confidential

A transport and exchange surface simulation was used to estimate the mass transport of a solution through the ash material. The direction of flow will either be from the UEVF aquifer into the pit water body or from the pit water body into the UEVF aquifer. The simulated effluent solutions from each transport scenario were then be mixed (using the ratios from Stage 2) with solutions representative of the pit water body and UEVF groundwater to determine the resulting concentrations in the receiving environment.

The stages of assessment are preliminary based on the groundwater and surface water quality collected during 2016 and 2017. As detailed within EHS Support 2017(o), additional characterisation of groundwater and surface water will be undertaken and this information will be used to refine and verify the concepts and evaluations presented in this review. This will take into account the future amendment activities which will modify the water quality of the pit water body.

Draft and Confidential

2.0 BACKGROUND

2.1 Historical Characterisation of Ash Materials

The Ash in the ponds was sourced from the ash materials generated from the furnace and electrostatic precipitators. The combined load of furnace ash and fly ash was transported by water sluices through piping to the Ash Ponds with the water recycled back into the process. In addition to the ash solids small volumes of water purification solids (iron and other impurities) were managed in the Ash ponds. It is unknown what the proportion of furnace ash to fly ash was deposited in the ash ponds, however, they are now likely to have mixed as a result of the sluicing to the ponds.

Historical characterisation of the Ash materials has been conducted by Alcoa and indicates that fly ash is enriched with trace metals reflecting with non-volatile metals accumulating in the Ash materials and or bound within the alkaline waste stream. Table 2-1 and Table 2-3 provide the chemical testing of the dry ash materials. Notable are the very low concentrations (< 10 mg/kg) of antimony, cadmium, chromium (hexavalent), mercury, molybdenum selenium, silver and tin. Arsenic, copper, lead and vanadium concentrations were also low (< 50 mg/kg).

As shown in Table 2-3, the majority of minor ions with the ash are not soluble are reported below the limit of reporting (based on the limit of reporting at the time of analysis) in ash pond 1 water. These include: aluminium, arsenic, beryllium, cadmium, chromium, copper, cobalt, fluoride, iron, mercury, nickel, phosphorus, lead, tin, antimony, vanadium and zinc. This is most likely due to the pH of the ash ponds, which is not conducive for the solubility of most metals. Total dissolved solids are elevated mainly due to the major ion concentrations.

On the basis of the historical testing, the key constituents with potential to leach from the ash materials at high concentrations is limited to boron.

2.2 Hydrogeology and Pit water body Geochemistry

Regional geology/hydrogeology of interest comprises two main hydrogeological units; the Eastern View Group (EVG) and the overlying Demons Bluff Group (DBG). The coal sequences targeted by the mine comprise the upper portions of the Upper East View Formation (UEVF). **Figure 2-1** provides a geological cross-section from the Otway ranges to the coast. The section indicates the location of the site and the coal beds relative to the water bearing sequences of the UEVF. The Lower East View Formation (LEVF), which has potable extraction wells, is located at depth and is separated from the UEVF by an aquitard (the middle east view formation, MEVF). Activities within the pit water body have no potential to impact on water quality within the LEVF.

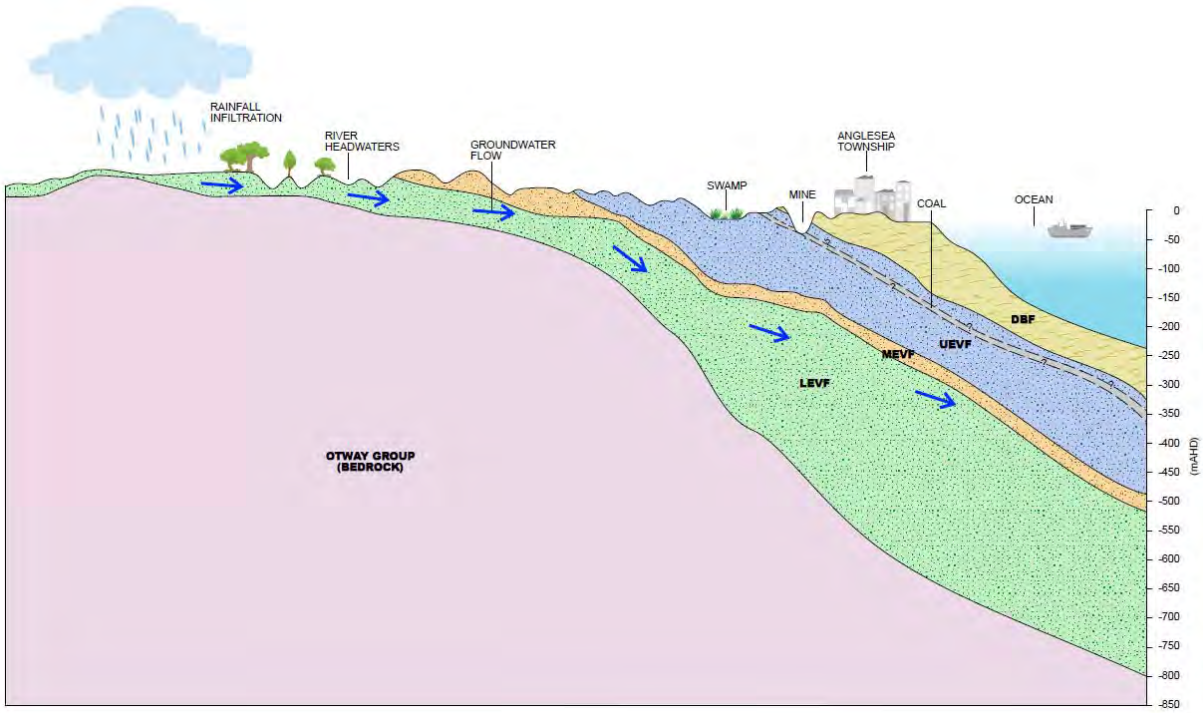

Figure 2-1 Regional Hydrogeological Cross-Section (Northwest to Southeast)

A basal clay unit is present beneath the main coal seam mined at the site and will separate the ash materials from the underlying UEVF. This unit which is between 3 to 10 m thick is plastic and exhibits low hydraulic conductivity.

As detailed in EHS Supports (2016), pumping of the UEVF for the provision of water to the power station and dewatering of the pit to facilitate mining has led to the development of a large cone of depression under the pit. The pit which was excavated to a depth of greater than -40 m AHD currently has a water level at around -38 m AHD with lake levels primarily a function of groundwater inflow (from the underlying UEVF) into the pit. Under this framework, groundwater flows are upward and therefore the potential for the flux of constituents from the buried Ash into the UEVF is considered limited and unlikely.

The planned pit closure approach involves rediversion of Salt Creek into the pit to accelerate both recharge of the underlying aquifer and pit water body filling. Under this framework, episodic flows from Salt Creek into the pit would result in lake levels higher than the underlying groundwater levels and potential flux (recharge) of the underlying UEVF.

The current pit water body quality is acidic (with a pH around 3) with the underlying groundwater exhibiting a pH of 5. Groundwater contact with oxidized pyritic materials and oxidation of iron-rich

Draft

water is responsible for the decline in pH. Alcoa has implemented a range of works to limit acid production including the covering of coals with spoils to limit oxidation and as the lake fills and oxygen is precluded from entering soils with acid production rates anticipated to decline over time. In addition, Alcoa is proposing to undertake the active management of pit water body pH, seeking to maintain the pH during filling at above 5.

If rediversion of Salt Creek into the pit water body is approved, then ultimately the water quality of the water body will be a function of surface water quality. Calculations of pit filling indicate filling times with surface water will be approximately 20 years with groundwater only and 5 years with groundwater and surface water (Salt Creek only). On this basis, at least 75% of the water within the lake would be sourced from Salt Creek.

2.3 Background Surface Water Quality

Following the diversion of Salt Creek into the pit water body, the water quality within the lake will primarily be a function of surface water inflows. The 53V Audit (GHD, 2012) noted that inflows of low pH water were the result of acid drainage from the upper catchment (Marshy and Salt Creeks). The low pH of water from both creeks is likely to result in a broad range of metals being present in surface water at elevated concentrations. General discussion of the data for Salt Creek and Marshy Creek is provided below.

Salt Creek is an ephemeral surface water system and is dry during periods of low flow and/or drought (GHD, 2012). The pH of water within Salt Creek is usually less than pH 4 (net acidic) with electrical conductivity (EC) of between 1,220 – 2,330 µS/cm. Boron, zinc, iron and aluminium are generally observed (refer to **Table 2-4**) to exceed the relevant guideline limits (freshwater ecosystems).

The Upper Anglesea River (sometimes referred to as Marshy Creek) is located upstream of the former power station facility. Similar to Salt Creek, the surface water pH is usually less than pH 4 (net acidic) with EC in Marsh Creek between 1,320 – 2,800 µS/cm). Boron, zinc, iron and aluminium within Marshy Creek generally exceed the relevant guideline limits (Australian and New Zealand Environment Conservation Council [ANZECC] maintenance of ecosystems – freshwater 95% protection). Further discussion on the water quality of Salt Creek and the Upper Anglesea River is provided in the sections below.

2.4 Conceptual Exposure Model and Beneficial Uses

In accordance with the Department of Health and Ageing and enHealth Council, Commonwealth of Australia (enHealth, 2010) and National Environmental Protection Measure (NEPM, 2013) a key component of assessing potential risks is defining a conceptual exposure model. As noted described above the key contaminant transport pathways are associated with migration of constituents into surface water within the pit water body and groundwater (the UEVF) underlying the pit.

Direct human and ecological contact with the Ash Materials is considered an incomplete pathway as the materials will be placed below -10 m AHD (and therefore below the level of the final lake) and will also be covered with silts and clays. Further other criteria, including Effects Screening Levels (ESLs, for terrestrial receptors), management criteria are also not applicable in this type of setting. A generic screening of soils against direct contact and leachability criteria has been provided in the sections below for reference only.

In accordance with the State Environmental Protection Policy (SEPP), protected beneficial uses are defined based on general water characteristics. The SEPP for Waters of Victoria requires that surface waters be of a suitable quality and quantity to support that use or value. The beneficial uses for each segment of the water environment are marked in **Table 2-4** below (using a tick) and the relevant

Draft and Confidential

segments for the site and vicinity (as determined within the 53V Audit 2012) are highlighted. Further discussion of each of the segments based on the 53V Audit are provided in the subsections below.

Where natural background surface water conditions do not meet the SEPPs list of environmental quality objectives (EQOs) for the listed beneficial uses of the segment rivers and streams, the background levels are used to define the EQOs*; (Pg 12; Gazette 26/02/1988, SEPP WoV).* As noted above background pH and dissolved metals (Boron, zinc, iron and aluminium) in Salt Creek and the Upper Anglesea River exceed applicable ANZECC water quality standards

Green shading – beneficial use segment upstream of site
Blue shading – beneficial use segment downstream of site

In the 53 V Audit (2012) for the site the following classifications were applied to the site by the Auditor:

- Salt and Marshy Creeks upstream of the Alcoa site – Forest-B (Otway Ranges)
- At the confluence of flows from Marshy and Salt Creeks and the licensed discharge (SP1) - Wetlands.
- Downstream of the mixing zone and within the Anglesea River – 'Estuaries and inlets' segment

Draft and Confi

The groundwater SEPP defines a range of beneficial uses based on Total Dissolved Solids (TDS) in groundwater. The lower the TDS, the greater the range of potentially beneficial uses (**Table 2-5**). Based on water quality data collected by Alcoa, the groundwater within the UEVF is classified as Segment B.

Table 2-5 Protected beneficial uses of the segments

Beneficial Uses	Segments (mg/L TDS)				
	A1 (0-500)	A2 (501-1,000)	B (1,001-3,500)	C (3,501-13,000)	D (greater than 13,000)

*consolidated version of the State Environment Protection Policy (Groundwaters of Victoria) 2002

In accordance with the SEPPs, water quality objectives for the protected beneficial uses are primarily sourced from 'Australian and New Zealand Guidelines for Fresh and Marine Water Quality', Australia and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand (ANZECC/ARMCANZ, 2000). Criteria utilised for each of the beneficial uses listed above include with applicable criteria are included in **Table 2-6** below:

- Maintenance of ecosystems beneficial use – the ANZECC/ARMCANZ (2000) 95% protection level trigger values for freshwater have been used, which are applicable to ecosystems that could be classified as slightly to moderately disturbed.
- Potable water supply – not applicable based on groundwater and surface water classification
- Potential mineral water supply – not applicable as the site is not located in a mineral springs district (Department of Minerals and Energy (1981), Groundwater Resources Map, 1981, 1:1,000,000 scale).
- Agriculture, parks and gardens – ANZECC/ARMCANZ (2000) Irrigation Water Guidelines.
- Stock watering – ANZECC/ARMCANZ (2000) Livestock Drinking Water Guidelines
- Industrial Water Use – ANZECC/ARMCANZ (2000) provides no specific guidance values and quality requirements are highly specific to the type of process. No criteria have been included in Table 2-6.
- Primary contact recreation – Australian Drinking Water Guidelines (ADWG, 2004) have been used as a generic guideline value however these are highly conservative.
- Buildings and Structures – There are no concentration based criteria and none have been included in Table 2-6.

In accordance with the SEPP, where background water quality precludes potential beneficial uses water quality objectives are defined as background. The background water quality for the UEVF and surface water in the catchment is provided as **Table 2-7.**

3.0 STAGE ONE – FIELD SAMPLE COLLECTION AND CHARACTERISATION

3.1 Field Sample Collection

The samples collected from Ash pond 1 have been used to provide detailed chemical information on the characteristics of the ash material and clay material used to construct the perimeter berm of ash pond 1. The ash ponds were constructed during the late 1950's and detailed records are not available regarding the material and engineering used to construct the ash ponds. The berm was only sampled in one location to confirm the material used to construct the berm wall. The berm material will not be excavated and transported to the pit void, it will remain in-situ and covered with locally available soils. Decommissioning of the ash ponds will provide further information on the construction and extent of the ash pond basal and sidewall containment engineering. The solid and aqueous samples have been restricted to three samples (in different locations). The decision to take this number of samples was based on the consistent geochemical quality of the lignite coal that was combusted to form the ash. The results of this sampling and analysis event has also been compared to historical ash analytical results to confirm the anticipated homogeneity.

Ash solid and aqueous samples were collected during June 2016 (refer to **Table 3-1** below).

Table 3-1: Solid and Aqueous samples

Sample Location	Sample Type	Sample Analytical Test	Number of Sample Locations	Total number of Samples
Ash Pond 1	Solid - perimeter berm	Solid characterisation and Ash solid and ash pond water leachate procedure	1	1
	Solid - main pond		3	3
	Surface Water - ash pond 1 water	Pond Water characterisation and Ash solid and ash pond water leachate procedure	3	3

The solid and aqueous samples were subjected to a detailed solid and wet chemistry analytical schedule (refer to **Table 3-2** and **Table 3-3**).

Table 3-2: Analytical Schedule for solid sampling

Analytical Group	Analytical Parameter
Laboratory analysis major ions	Calcium, magnesium, sodium, potassium, sulfate, chloride, alkalinity (total, bicarbonate and carbonate)
Laboratory analysis miscellaneous	Soluble sulfate
Laboratory analysis minor ions	Fluoride
Laboratory analysis (total) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, manganese, molybdenum, nickel, tin, lead, vanadium, zinc and mercury
Laboratory analysis (soluble) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, ferrous iron (dissolved), manganese, molybdenum, nickel, tin, lead, vanadium, zinc and mercury
Laboratory analysis physico-chemical	Particle size distribution (ash solids only), moisture content, exchangeable cations, pH, total acidity, total organic carbon
Laboratory analysis	pH1:2 and EC1:2
Laboratory analysis	Maximum potential acidity (MPA)

Draft and Confidential

Analytical Group	Analytical Parameter
Laboratory analysis	Acid Neutralising Capacity (ANC)
Laboratory analysis	Net Acid Producing Potential (NAPP)
Laboratory analysis	Net Acid Generation (NAG)

Table 3-3: Analytical Schedule for aqueous sampling

Analytical Group	Analytical Parameter
Field parameters	pH, temperature, turbidity, electrical conductivity, dissolved oxygen, redox potential
Laboratory measured 'field' parameters (where instrumentation is not available)	pH, turbidity, electrical conductivity, redox potential
Laboratory analysis major ions	Calcium, magnesium, sodium, potassium, sulfate, chloride, alkalinity (total, bicarbonate and carbonate), total hardness, total dissolved solids
Laboratory analysis minor ions	Fluoride
Laboratory analysis nutrients	ammonia as N, ammonium as N, nitrate as N, total kjeldahl nitrogen, total phosphorus, total organic carbon, dissolved organic carbon
Laboratory analysis (total) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, manganese, molybdenum, nickel, tin, lead, vanadium, zinc and mercury
Laboratory analysis (dissolved) metals	Aluminium, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, ferrous iron (dissolved), manganese, molybdenum, nickel, tin, lead, vanadium, zinc and mercury

A modified Australian Standard Leachate Procedure (ASLP) was also used to derive 'leachate' solutions from the mixing of ash solids with either UEVF groundwater or ash pond water.

3.2 Laboratory Analytical Results

The ash pond water samples have been characterised for water types and major ion distribution relationships using the AQaq program. AQqa (part of the Rockware group of software programmes) can be used to check the internal consistency and carbonate equilibria of data sets and plot a variety of graphs including Piper plots. It can also be used to compare between replicates or samples for low variances. Piper plots have been prepared using AQqa and are discussed in **Section 3.2.1.3**. Solid samples have been characterised using ternary diagrams for cation and anion distributions. The sample locations are provided **as Figure 3-1**.

Draft and Confidential

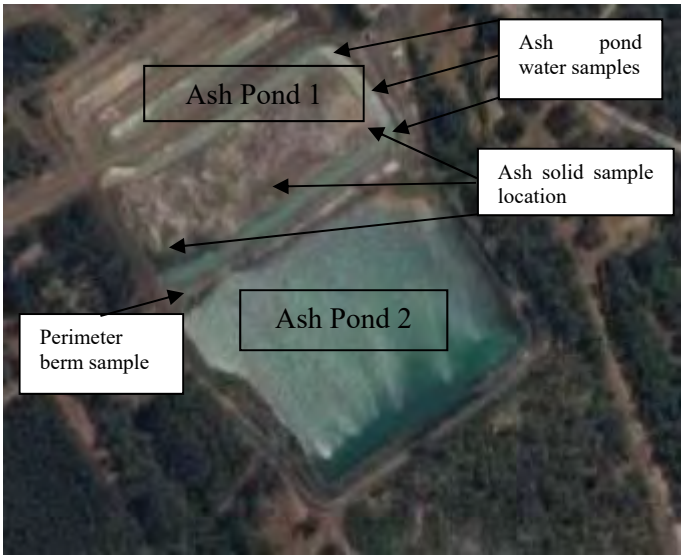

Figure 3-1 Ash solid and pond sample locations

It is noted that within some of analytical reporting for total and dissolved analytes, occasionally the dissolved concentration is higher than the total concentration. These results have been reviewed by quality control procedures and the differences reported are within the experimental variation of the analytical methods.

3.2.1 Ash Solids

As described above, three (3) samples of ash solids were collected from Ash Pond 1 and one (1) sample from the perimeter berm of Ash Pond 1 and analysed for the constituents list in **Table 3-2**. Two split samples of an ash solids replicate sample (PTH-16-0045 is a replicate of PTH-16-0042) were used in a modified ALSP test which used replicate samples of UEVF groundwater (PTH-16-0047 is a replicate of PTH-16-0046) and ash pond water (PTH-16-0040 is a replicate of PTH-16-0039) as the reagent waters (**Section 3.2.2**). The resulting leachate was then analysed using the same suite of analytical parameters used for other aqueous samples (refer to **Table 3-3**).

The results of the ash solid sample analyses are provided in **Attachment 1, Tables B-1 to B-4**.

The results of the ash solid ASLP leachate analyses are provided in **Attachment 1, Table B-5 to Table B-7**.

3.2.1.1 Physical Characteristics

The samples collected from within the Ash Pond are typically fine-grained with greater than 70% reported between 2 to 60 µm (silt fraction). The berm sample had a more uniform particle size distribution between clay, silt and sand and a much higher clay fraction than the Ash Pond samples. The Ash pond samples display a variable cation exchange capacity, with location 2 sample reporting 61.3 meq/100g and location 3 reporting 14.1 meq/100g. Location 1 and 2 samples are dominated by exchangeable magnesium, in contrast to location 3 and berm samples which are low in exchangeable magnesium. All samples report low exchangeable sodium, potassium calcium (refer to **Attachment 1, Table B-1).** The fine-grained characteristics of the ash solids and berm samples are likely to create a low hydraulic conductivity layer when deposited in Anglesea Pit. The presence of silts and clays has the potential to provide attenuation in the form of sorption surfaces for metal cations and major ions (sodium, potassium, calcium and magnesium).

Draft and Confidential

3.2.1.2 Ash Acid and Alkaline Generating Characteristics

Several tests were conducted on the Ash to characterise the acid producing and acid neutralizing potential. These tests included:

1. Total sulfur
2. Maximum Acid Potential (MPA)
3. Acid neutralizing capacity (ANC) expressed as percentage $CaCO_3$ and kg of H_2SO_4 equivalents per tonne
4. Net acid generation (NAG) at pH 4.5 and pH 7
5. Net acid production potential (NAPP)
6. Fizz rating

Initial pH screening tests (pHF and pHFOX tests) were not undertaken on the samples to determine the degree of acidity (unlike the native lithology solid samples [EHS Support, 2017b]). This was based on the historical geochemical characterisation of the ash and its anticipated alkaline nature.

The maximum potential acidity (MPA) can be estimated from the total sulfur content, although it is a conservative approach because it assumes all sulfur generates acidity under oxidising conditions. All the ash samples contained low amounts of sulfur (refer to **Attachment 1, Table B-2**). A conservative assessment of acidity potential using the sulfur concentrations estimates that low potential acidity production is possible.

ANC measures the amount of acid a sample can neutralise. The consumption of acidity by a sample is determined and expressed as kg H_2SO_4 equivalents/tonne. This reports the ability of a sample to neutralise (using its buffering capacity) any acidity generated. ANC is elevated in the ash solids so net acidity production potential (NAPP) is unlikely from the ash samples. The fizz rating for all three ash samples was reported as a 'very strong reaction' and Locations 1 and 2 were rated 5 where ANC is >400 Kg H_2SO_4/t.

Net acid generation (NAG) directly evaluates the generation of sulfuric acid within a sample. The NAG procedure includes a final titration to pH 4.5 and finally pH 7. The reported titration value at pH 4.5 includes acidity due to free acid (sulfuric acid, H_2SO_4) in addition to soluble iron and aluminium. The titration value at pH 7 also includes metallic ions that precipitate as hydroxides between pH 4.5 and 7. The results of the net acid generation (NAG) tests also support the low probability of acid production potential with the ash samples. The berm sample results are slightly different to the ash samples. Berm material reported negligible sulfur (0.13%), low MPA and ANC.

Net acid production potential (NAPP) represents the theoretical balance of a samples capacity to generate acid (MPA) and its capacity to neutralise (ANC). If the MPA is less than ANC, then the NAPP is negative and the sample may have sufficient ANC to prevent acid generation. However, if the MPA exceeds the ANC then the NAPP is positive and the same may be acid generating. All three ash samples report negative NAPP values, whereas the berm sample records a slight possibility of NAPP (0.9 kg H_2SO_4/t).

The acid forming potential is plotted as **Figure 3-2**, which shows locations 1, 2 and 3 as non-acid forming and the berm material on the boundary of non-acid forming and uncertain. Even if the berm material is capable of generating acidity the potential amounts are negligible and will be neutralized by the higher ratio of ash solid to berm material.

Draft and Confidential

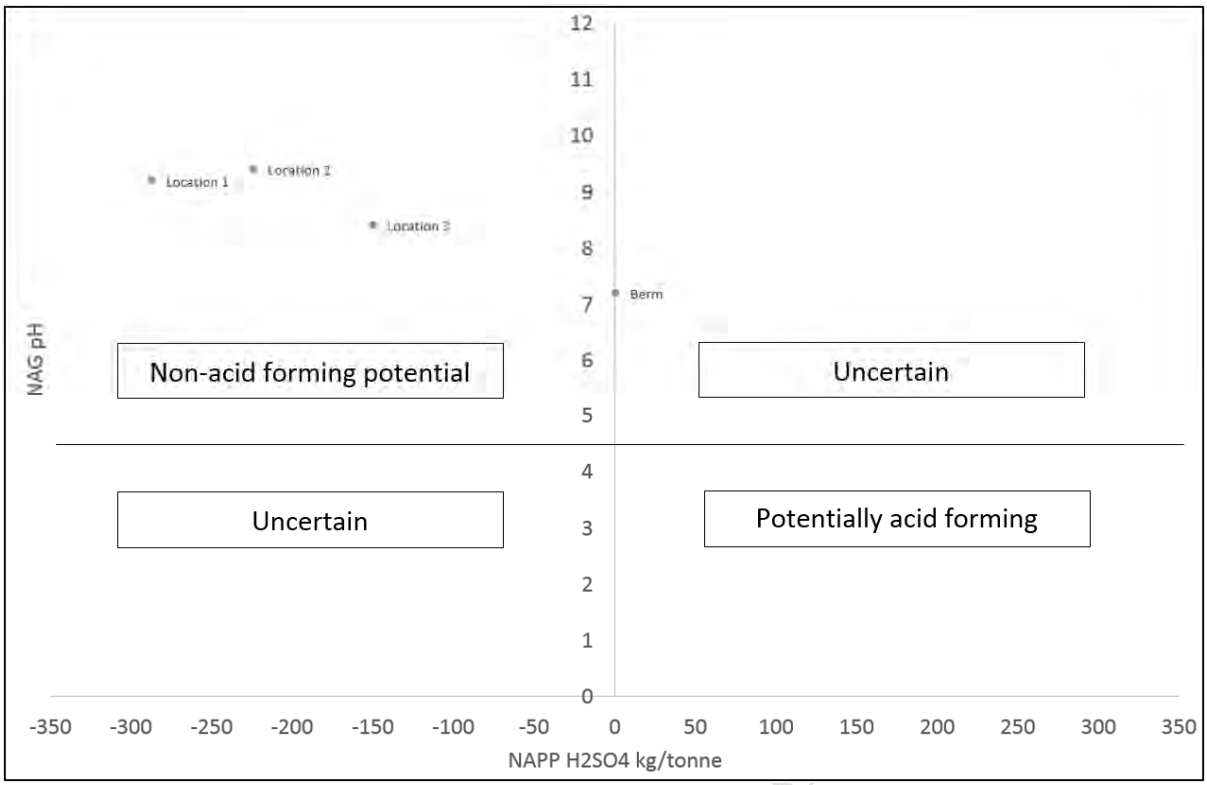

Figure 3-2: Ash Pond and Berm samples - Acid Forming Potential Plot

In summary, the ash material represents an elevated capacity for acid neutralisation and when initially deposited in the Anglesea Pit will provide buffering capacity to mitigate the effects of acidity produced from geogenic pyritic materials. In the short-term the ash deposits in the pit void will be covered with clay overburden material from the Demons Bluff Group (DBG) overlying the coal (Seam A). The clay component of the DBG was identified and segregated during the development of the coal mine based on the requirements of future rehabilitation works

3.2.1.3 Major Ions

The major ion concentrations (mg/kg) for the ash and berm samples are plotted as ternary diagrams in **Figure 3-3**.

Draft and Confi

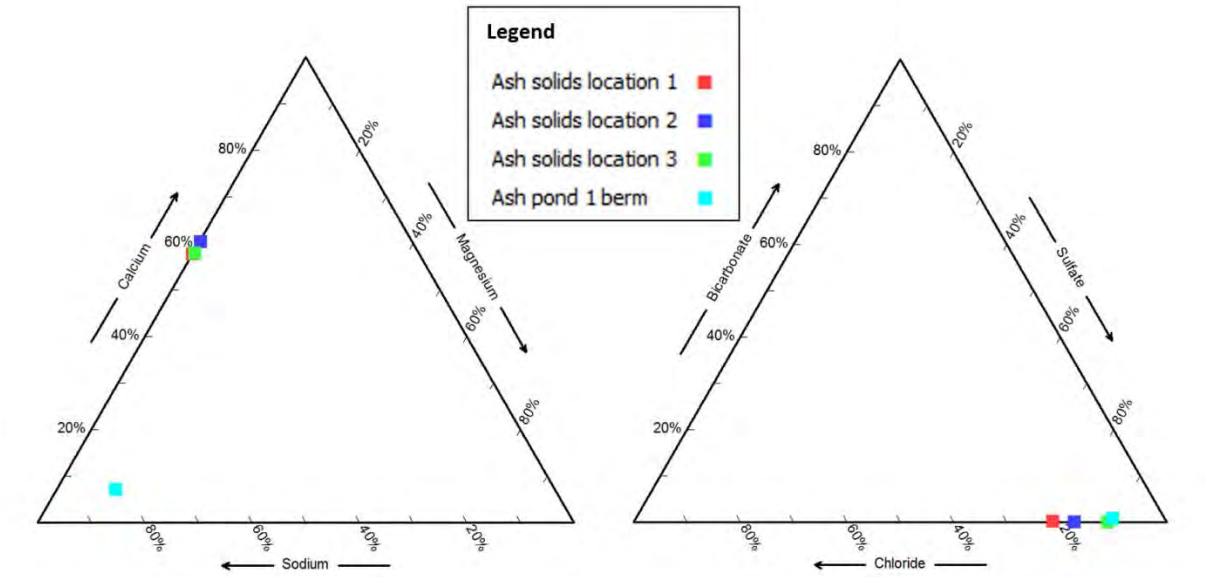

Figure 3-3: Ash pond solids and berm samples – Ternary diagram Major Cations (mg/kg)

The ternary diagram is similar to a Piper plot where the relative mass concentrations are plotted for cations and anions. It is evident from the cation plot that the ratio of calcium, magnesium and sodium is different between the ash solid and berm samples. The berm sample reports a lower calcium and sodium and higher magnesium concentration than the ash solid samples. This is likely to be related to the type of material used to construct the berm wall. The anion ratios appear to plot closely for all four (4) samples, in particular samples collected from Location 3 and the berm. This is due to the dominance of sulfate over chloride and bicarbonate in the samples and is not related to any similarity between the ash solid and berm samples major ion concentrations. The major ion and total organic carbon concentrations, electrical conductivity and pH are provided in **Figure 3-4** and **Attachment 1, Table B-4**.

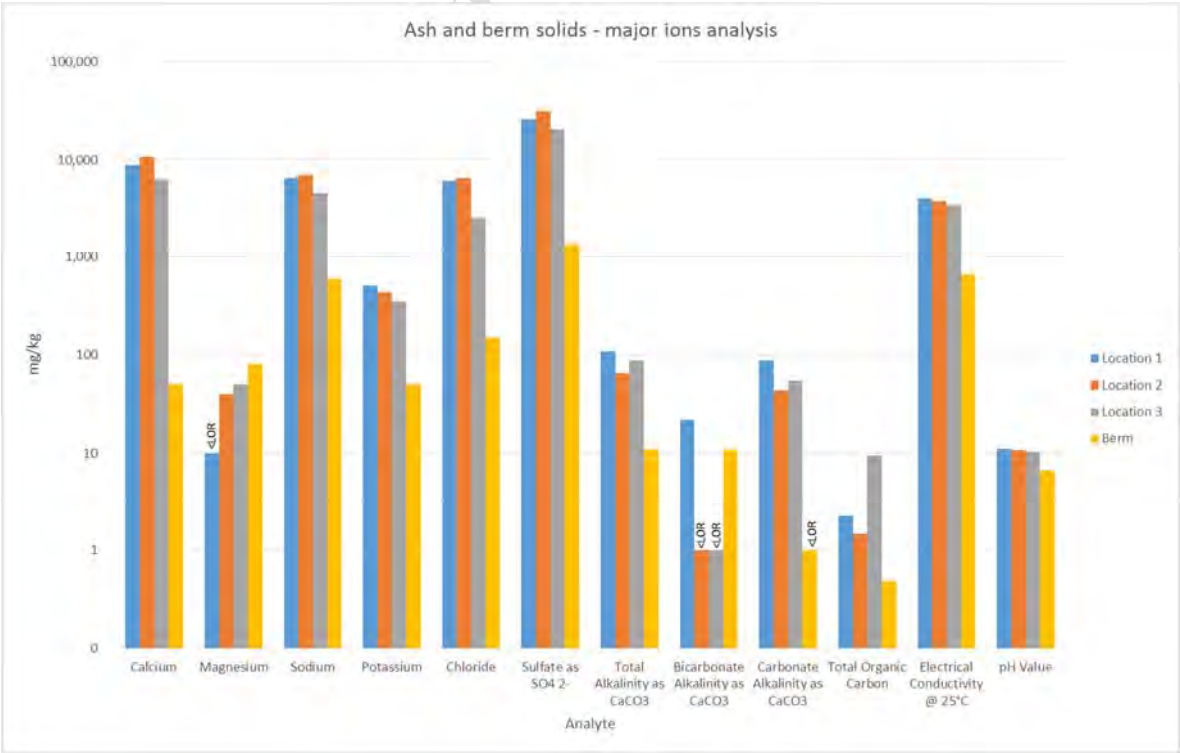

Figure 3-4: Ash pond solids and berm samples – major ions, organic carbon and physico-chemical analytes

The presence of organic carbon in the ash solids is unlikely to be related to be related to the source material (coal) due to the combustion process. The ash ponds are vegetated and the process of decaying vegetation will release organic carbon into the ponds and sediment.

3.2.1.4 Metals, metalloids and minor anions

The ash solid samples are characterised by elevated concentrations of aluminium, barium, boron, iron and manganese. The berm also reports elevated aluminium and iron but low (by comparison) boron, barium and manganese concentrations (refer to Table B-3). The ternary plot in **Figure 3-5**, illustrates the variability in metal and metalloid distribution between the locations within ash pond 1 and in the berm.

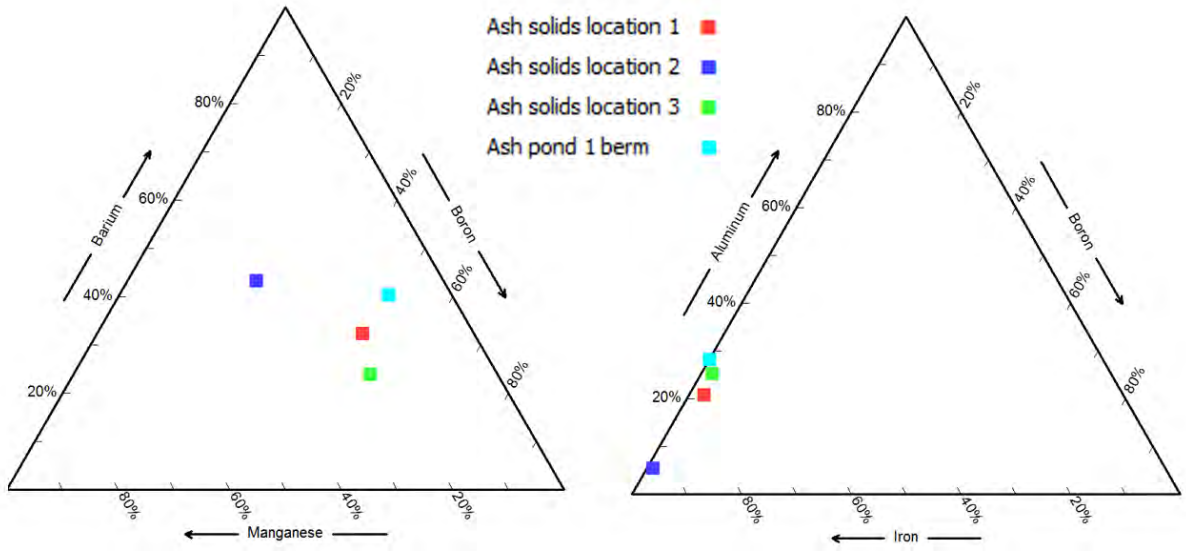

Figure 3-5: Ash pond solids and berm samples – Ternary diagram metals and metalloids (mg/kg)

Cadmium, molybdenum, tin and selenium all reported concentrations below the laboratory limit of reporting (LOR), refer to **Figure 3-6**.

The analytical results for ash solids fall within similar ranges of concentrations presented in previously published references (Beattie, 2003 and GHD, 2012).

Draft and C

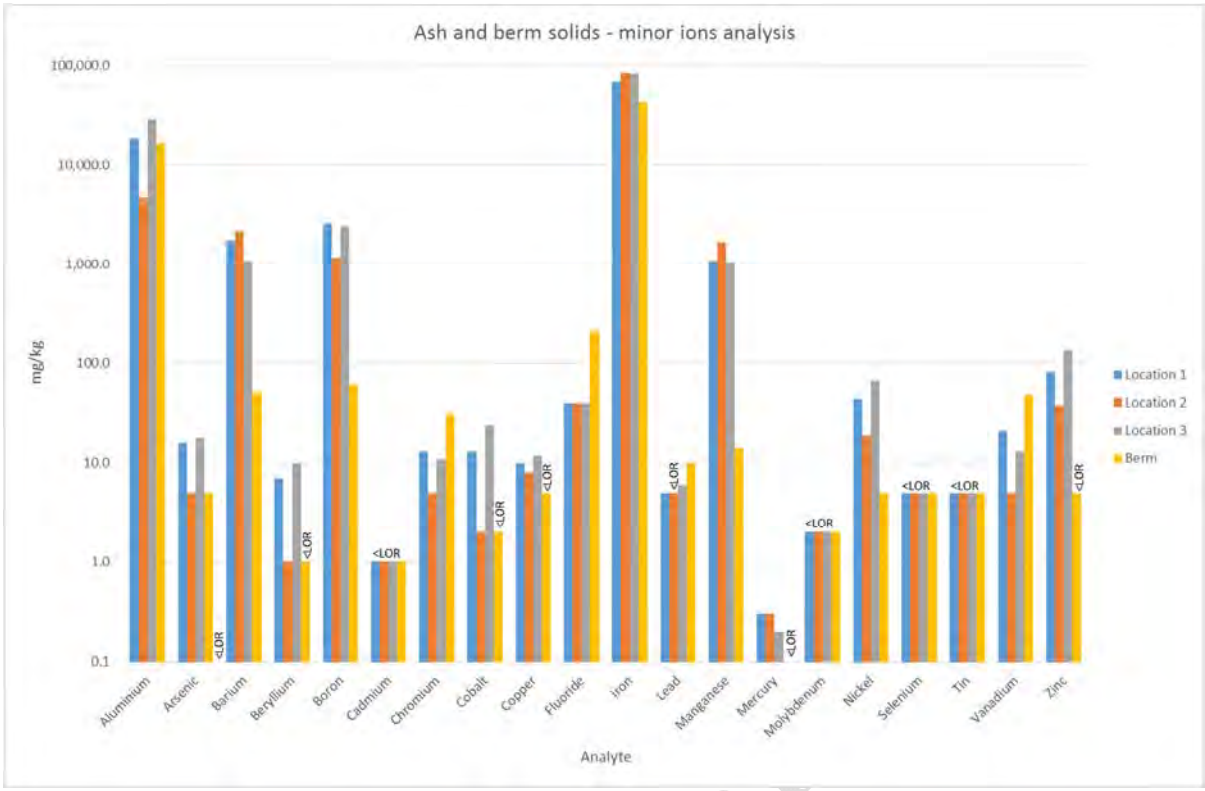

Figure 3-6: Ash pond solids and berm samples – minor ions

3.2.2 Ash Pond Solids – ASLP Results

Two (2) samples of ash solid material were leached using UEVF groundwater and ash pond 1 surface water as reagent waters. The ASLP method was used for the leachate procedure but instead of using a laboratory derived reagent water (pH 5), site representative reagent waters were used. The site derived reagent waters, UEVF groundwater and ash pond water, were selected because UEVF groundwater may come into contact with ash solid material when it is deposited into Anglesea pit. The ash pond water has been in contact with the ash solid material for an extended period of time (years to decades). The comparison between ash pond water and the leachable analyses provides an indication of the equilibrium between the ash pond water and solid material and future porewater characteristics within the ash material at the base of the Anglesea pit.

Analytes which reported variances between the reagent water and leachable results concentrations have been plotted as **Figure 3-7** and **Figure 3-8**.

The results of the ash solid sample analyses are provided in **Attachment 1, Tables B-5 to B-7**.

3.2.2.1 Reagent Water 1 – Ash Pond 1 water

The ASLP results for the ash pond water and ash solids indicate that the main variances between the analyses are related to alkalinity and pH. The pH is observed to increase from pH 8.22 (ash pond water) to pH 9.8 (leachate). Accompanying the increase in pH, are increases in carbonate and hydroxide alkalinity and a decrease in bicarbonate alkalinity. The changes in relative abundancy of alkalinity species is as expected with the change in pH. It is likely that the increase in pH initially occurred when water came into contact with the ash material within the ponds. Over time, the hydroxide species would have been scavenged by metal cations to form insoluble precipitates, which in turn would have decreased the pH. As observed within **Figure 3-7**, most of the analytes report negligible changes between ash pond water and the resulting leachate. This supports the hypothesis that the ash pond water is anticipated to be in equilibrium with the ash solids within Ash Pond 1.

Draft and Con

3.2.2.2 Reagent Water 2 – UEVF groundwater

The ASLP results for the UEVF groundwater and ash solids report an increase from pH 6.58 (ash pond water) to pH 8.8 (leachate). The leachate pH is observed to be lower than that reported for the ash pond water leachate result. The leachate is likely buffered against greater pH increases due to the precipitation of iron (oxy)hydroxides which produces acidity. As observed in **Figure 3-8**, iron concentrations decrease to non-detectable levels in the leachate. Increases in boron, calcium, potassium, sodium, sulfate, carbonate, ammonia and dissolved organic carbon are reported in the leachate. Magnesium and bicarbonate concentrations are lower in the leachate in comparison to the UEVF groundwater. The changes in major cation concentrations is likely to be related to cation exchange reactions on the ash solid surface. Reduced nitrogen species are elevated in the leachate, which may be related to reduction of organic carbon during the ASLP. As discussed in **Section 3.2.1.4**, the ash solids are characterised by elevated concentrations of aluminium, barium, boron, iron and manganese. Only boron is reported to be elevated in the leachate which is due to its anionic form over the observed pH range. Aluminium, barium, iron and manganese all form solubility limiting phases over the pH range reported and are expected to precipitate as insoluble phases.

Draft and Confidential

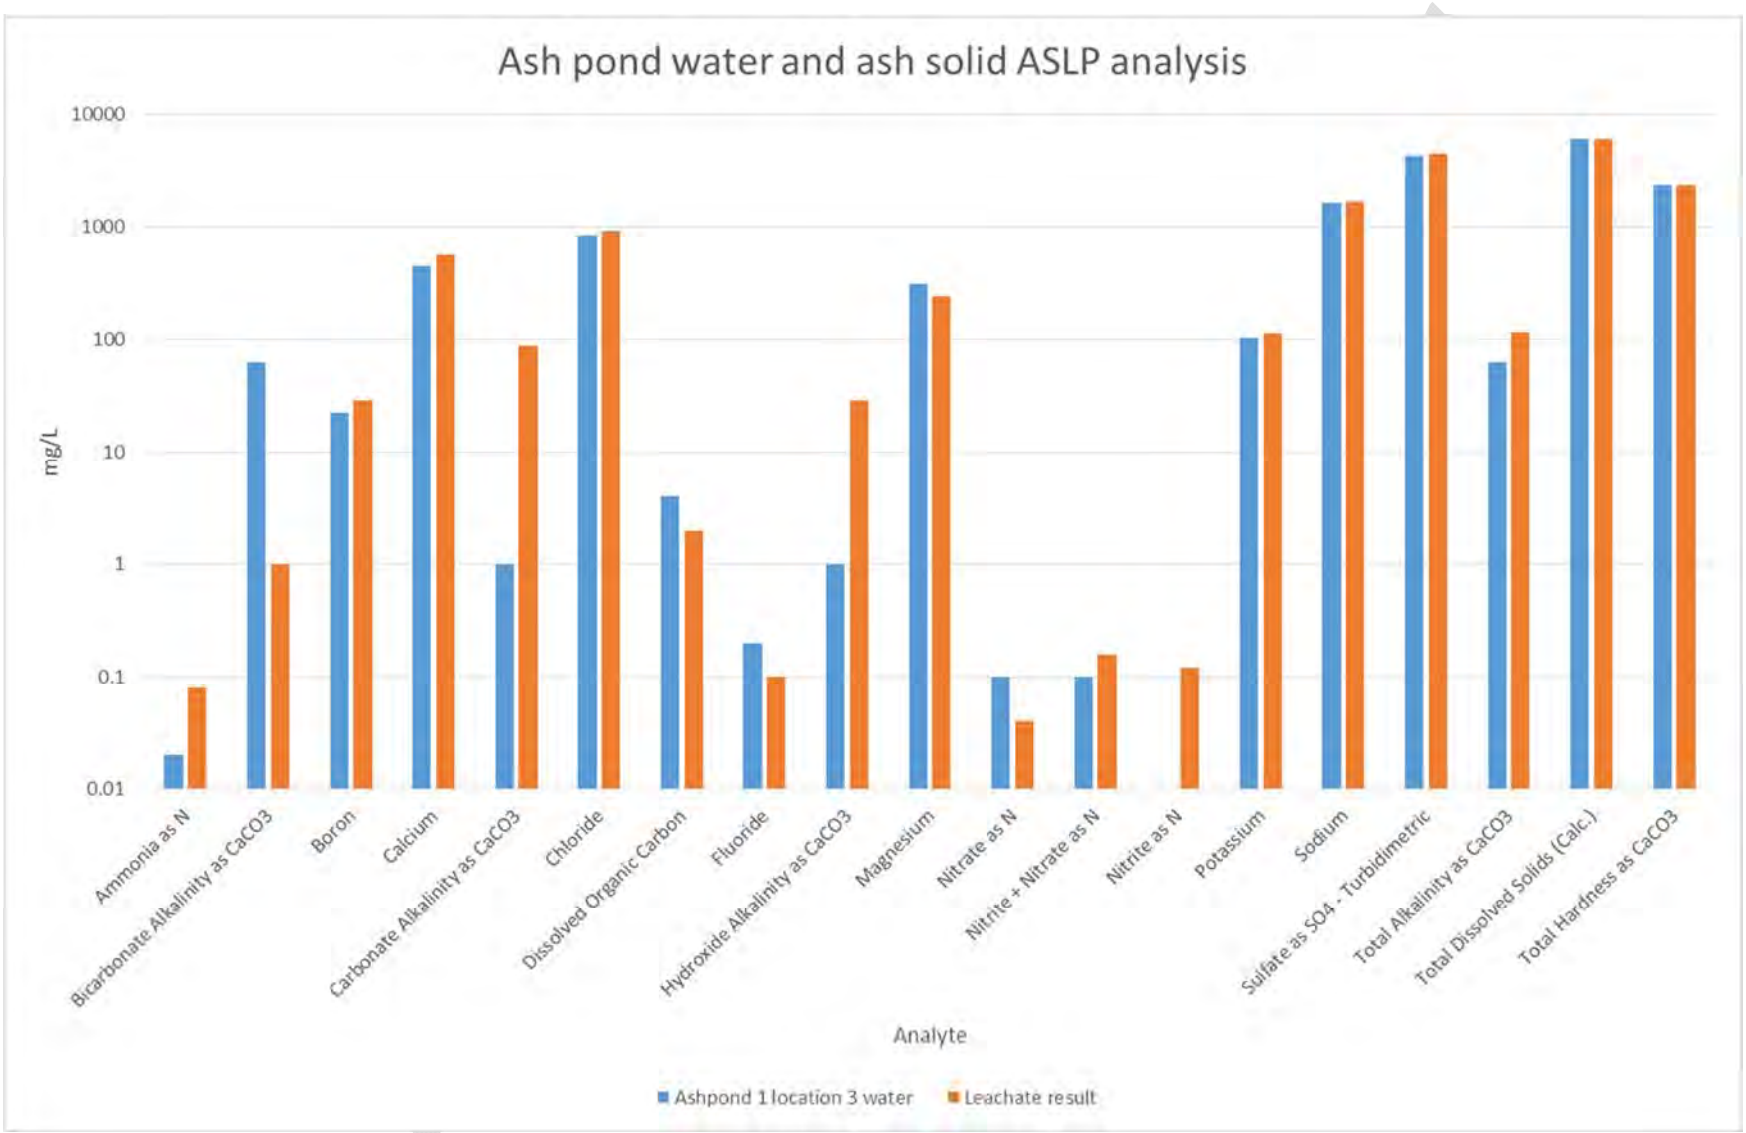

Figure 3-7: Ash pond water and Ash Solid ASLP results

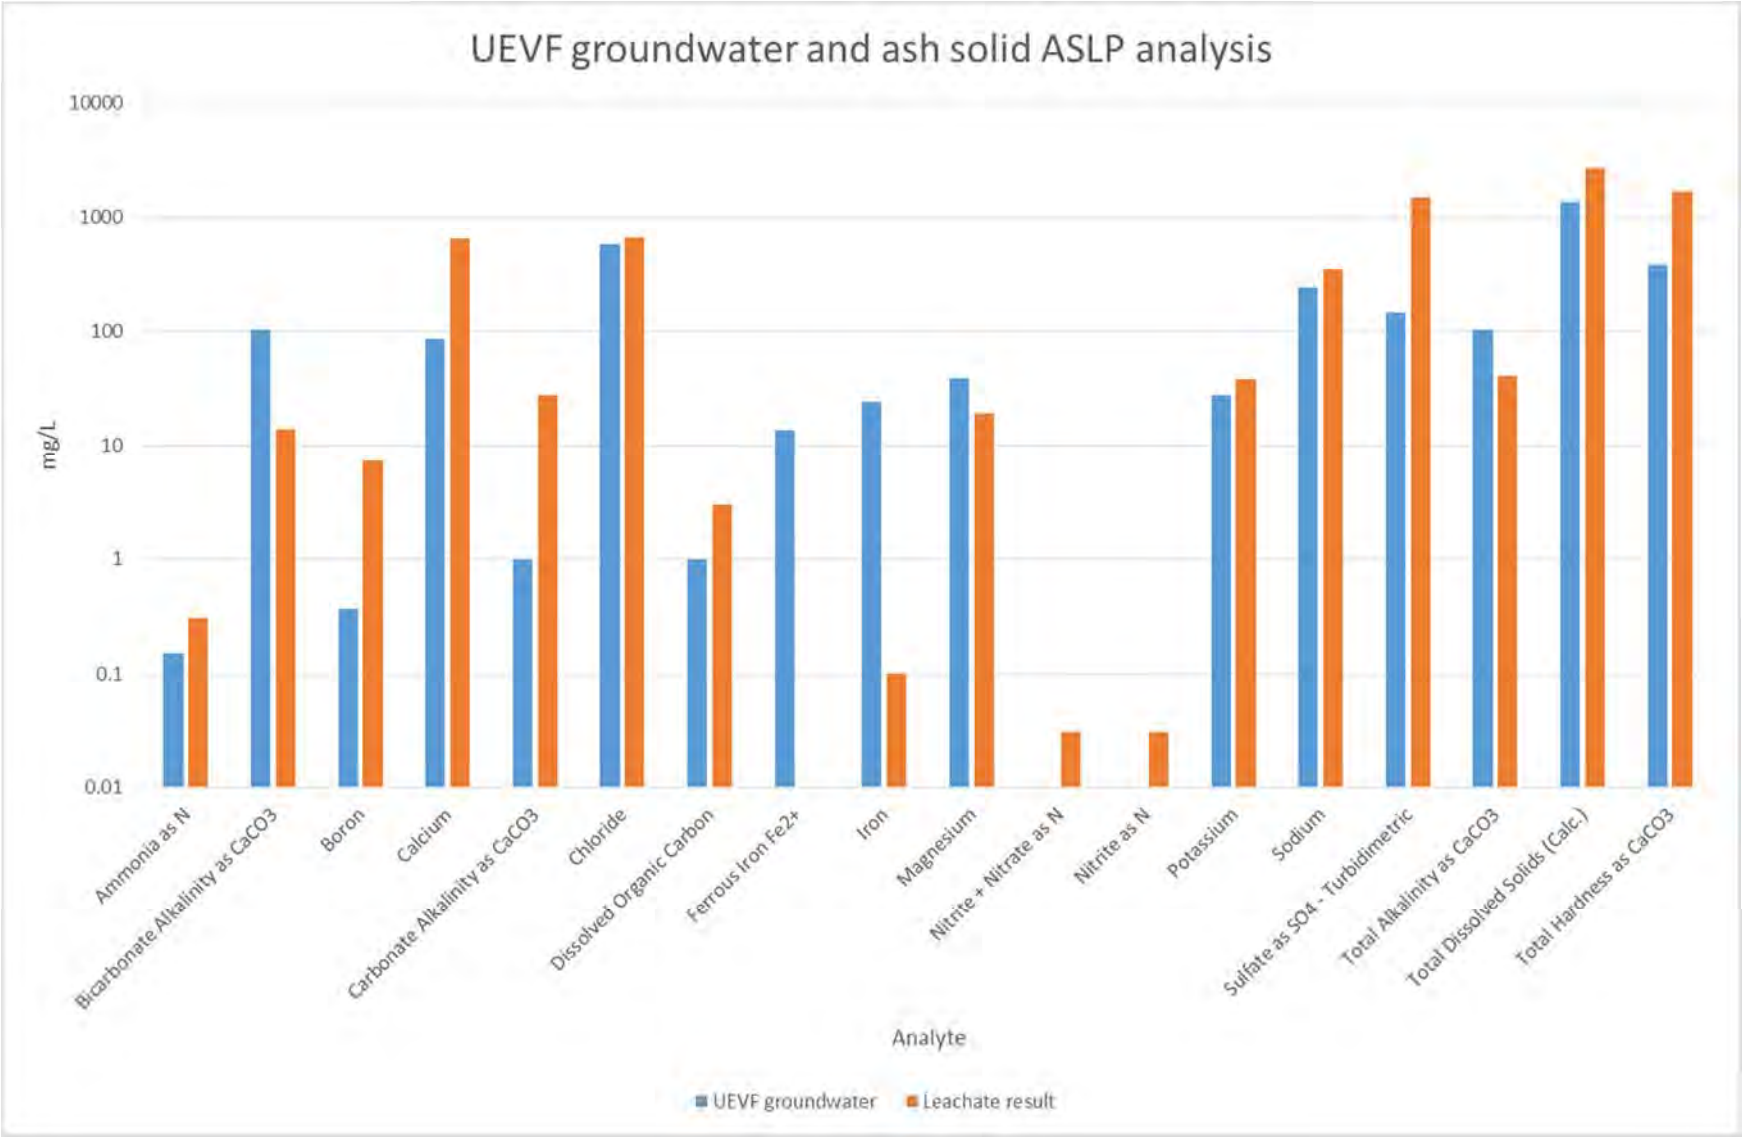

Figure 3-8: UEVF groundwater and Ash Solid ASLP results

3.2.3 Ash pond water and UEVF groundwater

The comparison of analyte distributions within the UEVF groundwater and ash pond water has been evaluated. Groundwater is expected to be in equilibrium with the UEVF aquifer lithology and the ash is derived from the burning of coal sourced from the UEVF. Groundwater derived from the UEVF aquifer was also used in ash slurrying processes historically carried out at the former facility. It is therefore anticipated that similar chemistry will be observed between the UEVF groundwater and ash pond water.

Three (3) samples of ash pond water were collected from ash pond 1 and one (1) sample from well bore 15 (WS4) which is screened within the UEVF aquifer. A range of analysis was carried out on the water samples which included:

1. Major ions;
2. Total and dissolved minor anions; and
3. Nutrients.

3.2.3.1 Major Ions

Major ions for four (4) samples have been graphed as a Piper plot. These comprise one (1) sample from the UEVF groundwater and three (3) samples from Ash pond 1.

As observed in **Figure 3-9** the cation ratios for the UEVF and ash pond water are very similar with sodium as the dominant cation. The similar cation ratios are indicative of the bedrock mineralogy influences where the UEVF groundwater resides and which is also the source of the coal (burnt to produce the ash). The anionic ratios display the dominance of the sulfate ion (in the ash pond water) and the chloride ion (within the UEVF groundwater). As a result, the UEVF groundwater plots as a sodium chloride water type and the ash pond water is a sodium sulfate water type. All the ash pond samples are supersaturated with calcium carbonate which is a function of the pH (average pH 8.25). The UEVF groundwater reports a lower pH 6.58 and is under saturated with respect to calcium carbonate.

Major ion distribution is very similar between the UEVF groundwater and ash pond water as observed in **Figure 3-10** and **Figure 3-11**, although there is an order of magnitude concentration difference between groundwater and ash pond water quality.

3.2.3.2 Minor Ions

The UEVF groundwater is characterised by low to non-detectable concentrations of minor ions. Total and dissolved arsenic, beryllium, cadmium, chromium (dissolved only), cobalt, copper (dissolved only), lead, mercury, molybdenum, nickel, selenium, tin, vanadium and zinc are all reported below the laboratory LOR. Iron, manganese and boron (total and dissolved) report the highest concentrations in this suite of analyses (refer to **Figure 3-12**).

The ash pond water is also characterised by low to non-detectable concentrations of minor ions. Total and dissolved arsenic, beryllium, cadmium, chromium, copper, iron, lead, mercury, selenium, tin and vanadium are all reported at or below the laboratory LOR. Minor ion distribution is dominated by boron (> 10 mg/L), followed by aluminium, barium and manganese (refer to **Figure 3-13**).

Draft and Confidential

3.2.3.3 Nutrients

Nutrients reported within the UEVF groundwater sample were all below the laboratory LOR except for Ammonia (as N) which recorded a value of 0.15 mg/L. A plot has not been prepared for UEVF groundwater nutrient concentrations.

As discussed in Section **3.2.1.3**, the organic carbon measured within the ash solids is most likely to be derived from vegetation growing within the ash ponds. Organic carbon is also detected within the ash pond water (refer to **Figure 3-14**), in association with low concentrations of ammonia (as N) and nitrate (as N).

3.3 Assessment of ASLP and Pond Water Samples against Screening Criteria

Consistent with the discussion above, direct contact with the Ash materials and Pond 2 iron floc, after placement and lake filling, is considered an incomplete exposure pathway and therefore the soil sampling results were not screened against regulatory criteria. Assessment of soil and sediment data relative to leaching to groundwater criteria indicates that a range of metals in the ash and floc materials exceed generic leaching to groundwater screening criteria (NEPM and USEPA RSLs) for the protection of drinking water quality. It should be noted that this assessment methodology is highly conservative with the low permeability and high pH and Cation Exchange Capacity (CEC) of the ash limiting the potential leaching of metals. Considering this limitation, a direct assessment of leaching potential (ASLP testing) was conducted using Pond water and UEVF groundwater.

ASLP testing conducted using Ash pond (and associated pore water within the Ash materials) and the lower pH of the UEVF indicated limited leaching potential for metals from the ash materials. The leachate from these tests indicated that the majority of metals were strongly bound to the ash matrix. Boron, ammonia, nitrate/nitrite were the only constituents detected in the leachate from the ASLP. However, it should be noted that the reporting limits for a number of other metals were above generic water screening criteria.

Assessment of the exceedances relative to relevant and applicable criteria indicates that only Boron exceeded potentially applicable groundwater and surface water criteria. It is noted that the detection limits for a number of other metals were higher than the screening criteria. The DAF required for Boron to achieve groundwater and surface water criteria is small and was calculated to be only 7.25 and 78.38, respectively.

For the other trace metals with reporting limits above the very low generic screening criteria, it should be noted that the water quality criteria are naturally exceeded for metals in surface water (aluminium, boron and zinc and likely other metals exceed maintenance of aquatic ecosystems criteria)..

Draft and Confidential

The Ash Pond water samples (collected from water in direct contact with ash) provided lower analytical reporting limits and confirm the results of the ASLP testing with only aluminium (maximum 0.12 mg/L) and boron (maximum 24 mg/L) exceeding the water quality criteria (refer **Table 2-7**). This indicates that only boron is leachable and exhibits s mobility. Using these values the DAF for Boron to comply with regulatory criteria are 6 and 64, for groundwater and surface water respectively. These values are similar to the values calculated with the ASLP results.

It should be noted that this assessment is highly conservative as it does not consider geochemical reactions within the ash or other stratigraphic units. However, the assessment is suitable for identifying constituents of potential concern.

Draft and Confidential

4.0 STAGE TWO – HYDROGEOLOGIC CONCEPTUALISATION OF FLUXES

As described above, the management of ash is being conducted in a designated area of the mine pit. The ash materials will be covered by spoil comprising silts and clays removed during the mining operation. The block model below conceptualizes the placement and cover of the ash materials and ultimate the future situation where the ash management area is submerged beneath the lake. The key hydrogeologic controls on fluxes are the low permeability of the basal clay, the ash materials themselves and the silts and clays that will be used to cover the ash.

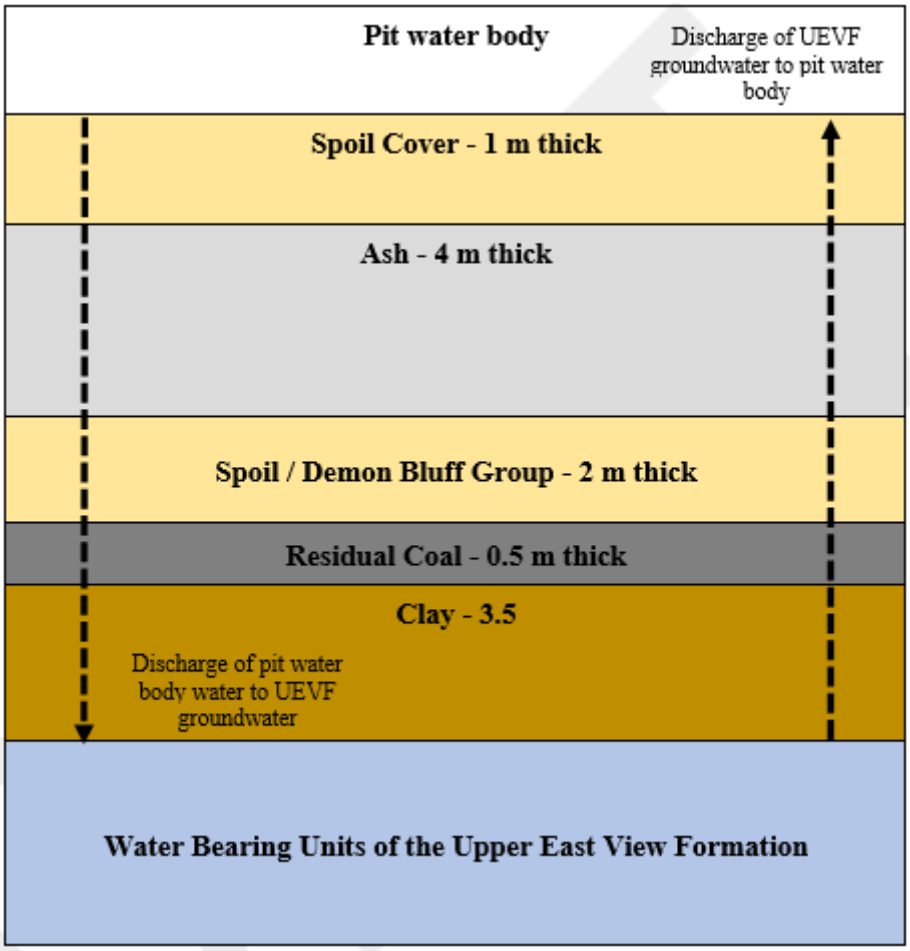

Figure 4-1: Block Model

Included in the simple block model (**Figure 5-1**) are the anticipated flow pathways between the pit water body and the UEVF aquifer associated with the diversion of Salt Creek (strong downward gradients) and steady state conditions (weak upward gradients in response to evaporation only.

It should be noted that this simple block model was conducted in addition to the numerical modelling (EHS Support 2017(e)) which assessed advective transport and determined that transport of constituents in groundwater would not occur away from the pit and if Barwon Water commenced pumping from the LEVF advective travel times would be very long (> 4,000 years).

4.1 Inputs and Assumptions

Darcy's Law (Eq 1) was used to calculate the flux of water that passes through the Ash layer (either upwards or downwards) as well as the pore space velocity

$$\text{Darcy Flux} = q = Ki \quad \text{and} \quad \text{Pore Space Velocity} = v = \frac{q}{\eta} \qquad (1)$$

Where K = Hydraulic conductivity (m/d); i = hydraulic gradient; and η = formation porosity (-).

The horizontal hydraulic conductivity (Kx) for each unit were adopted from EHS Support (2017f) with the exception of the top 1m cover. Whilst this cover generally comprises of the Demon Bluff Group (DBG) sediments, this cover will generally have a higher clay content (pers com Chris Rolland 2017) and also will be compacted in parts by heavy machinery. As such it was conservatively estimated to have an order of magnitude lower K than the broader DBG. For the remaining units, an anisotropy of Kx:Ky (1:10) was used define vertical hydraulic conductivity (Kv).

The hydrogeological parameters are presented in **Table 4-1** and **Table 4-2** and the cross-sectional area of permitted ash placement was estimated to be a maximum of 110,000 m^2 (refer **Figure 4-2**– note although other field data indicates it may be closure to 70,000 m^2). The thicknesses and depth of the clay unit below the residual coal seam presented in **Figure 4-1**, was obtained from geotechnical bore log GT2016-03 located, refer to **Figure 4-2**.

The hydraulic gradients were calculated by assuming the following:

4.1.1 Upward Gradient (Movement from UEVF to Pit water body)

Once the Lake reaches a steady state condition where groundwater heads will be roughly in equilibrium with the lake level, an upward gradient will exist where evaporation of the lake surface will be the major driver of this gradient. To calculate this gradient, the difference in head between the lake level and the groundwater elevation was divided across the distance between the bottom and the top of the Ash (-15mAHD, to -10mAHD).

4.1.2 Downward Gradient (Movement from Pit water body to UEVF)

As the Pit water body fills with surface water, there will be a gradient from Pit water body to groundwater. This is expected as lake levels are anticipated to be higher than the groundwater elevations, refer to **Figure 4-3**. To calculate this gradient, the thickness of the materials between the base of the Pit water body and the top of the UEVF was divided by the modelled maximum head difference between the UEVF (upper sands) and the Lake level. This was estimated to be 17m, refer to **Figure 4-3**. It should be noted that this is the maximum gradient and based on travel times through the basal clay (approaching 2.5 years) a lower average gradient could be used in the calculations. Further this gradient will only occur for the short time period of lake filling (when groundwater levels are lower than surface water levels).

Therefore, the resulting gradient is 17m/11m = 1.5

For each scenario, the resulting Darcy flux is presented in **Table 4-1** and **Table 4-2**.

The fluxes are a function of the areas of the ash management area and the total pit area. The ash management area makes up 90,000 m2 of the total pit area of 1,280,000 m2 which is effectively 7% of the total area.

Draft and Confidential

Furthermore, using Eq 1, and adopting modelled layer porosities, **Table 4-1** and **Table 4-2** present pore space velocities (and in turn conservative particle travel time) for each scenario above.

It should be noted that the current day scenario of Flux from UEVF to Pit water body was not modelled as UEVF groundwater is currently not in communication with the base of the Ash. The current recovering groundwater heads for the UEVF (upper sands) are ~-26m AHD (refer **EHS Support 2017(a,d)**. Referring to **EHS Support 2017(e)** UEVF heads will not reach -14mAHD (base of the ash layer) for approximately 20 months or sometime early 2019). It is anticipated that the surface water diversion will be commissioned prior to this time (estimated to be Q3, 2018) and as a result, Pit water body levels should remain higher than UEVF groundwater until near steady State time is achieved.

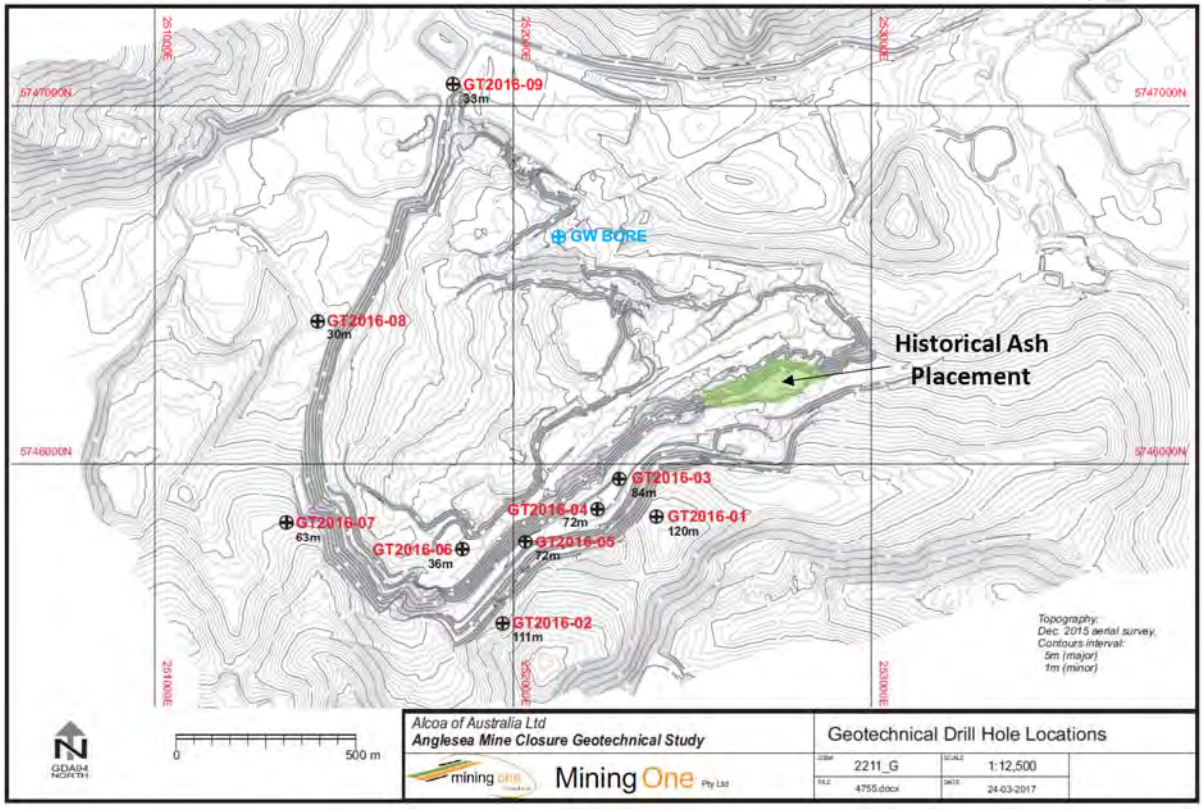

Figure 4-2: Historical Placement of Ash (Modified from Mining One 2017)[l]

Draft

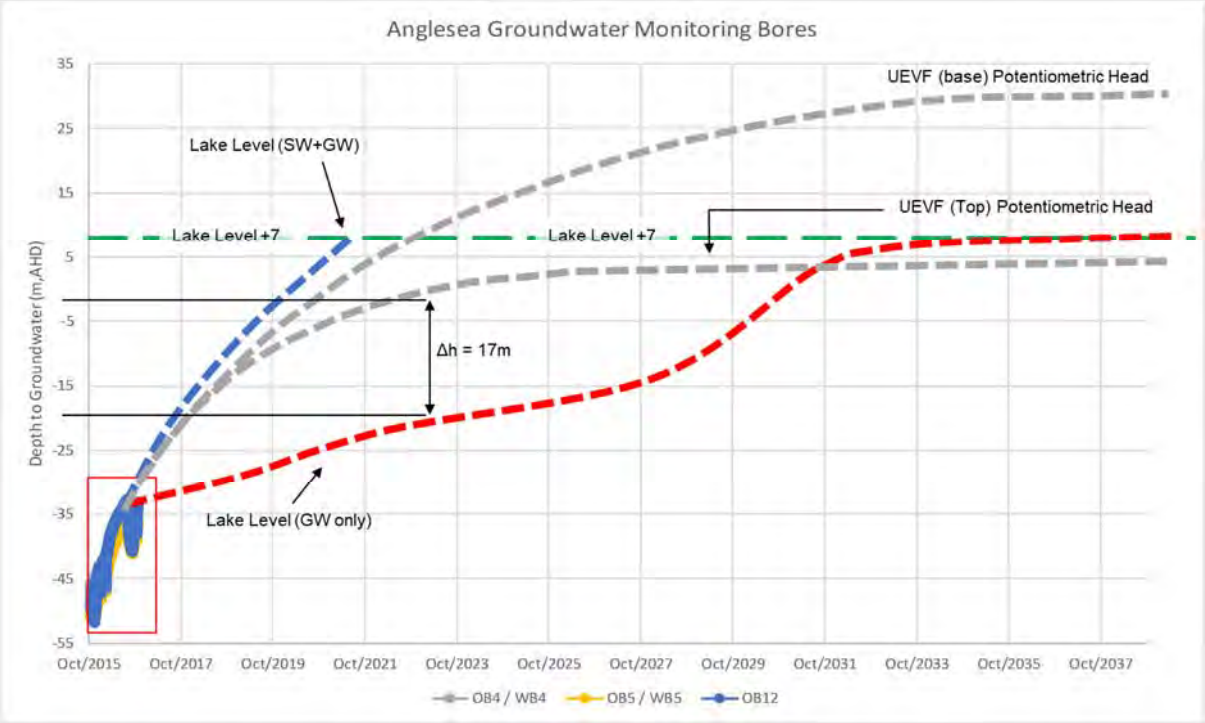

Figure 4-3: Modelled Groundwater and Pit water body Level Recovers (refer EHS Support 2017(e)

4.2 Analytical Block Model Results

Based on the simplified assumptions using areas and calculations of groundwater flux (based on heads and the hydraulic properties of the underlying aquifers) as presented above, dilution attenuation factors (DAFs) can be calculated. The block model (**Figure 4-4**) conceptualises the sequence of lithologies along the flow pathway between the pit water body and the UEVF aquifer. The characteristics of each lithological layer is summarised in **Table 4-1** and **Table 4-2**.

Based on the relationship between the vertical and horizontal flow volumes of water within the clay and underlying UEVF layers, DAFs have been calculated for the upward recharge and downward discharge of water flow.

Draft and Confi

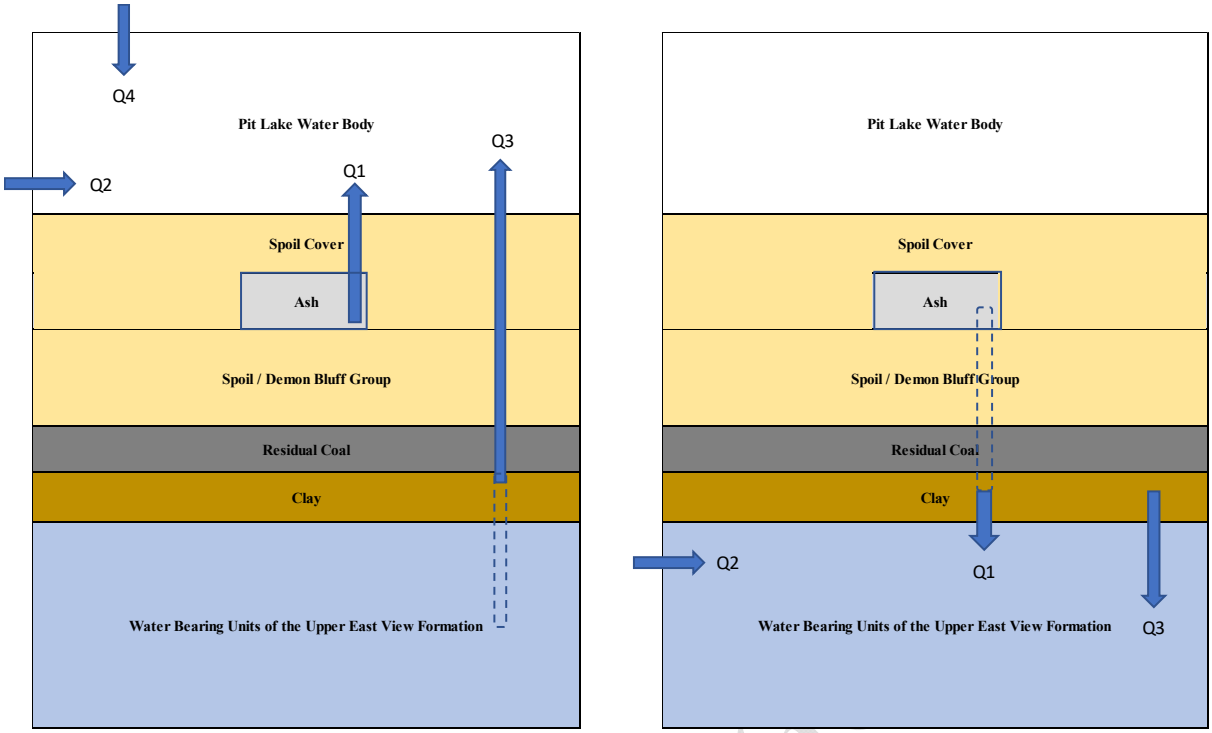

Figure 4-4: Flux Conceptualizations to calculate the DAF. (Left) Upward gradient Scenario (Right) Downward gradient scenario

Dilution attenuation can be described as the flux of water flowing through a mixing zone, divided by the flux of groundwater flowing through the source zone. In this case the mixing zone is either the Pit water body (for the upward gradient scenario, or the UEVF for the Downward gradient scenario. The source zone is the Ash compartment. Therefore, using **Figure 5-4** as reference the following equations were used to calculate the DAFs;

4.2.1 Upward Gradient (Movement from UEVF to Pit water body)

$$DAF = (Q1+Q2+Q3+Q4) / Q1$$

Note: As the clay layer present under the pit constrains the flow, the hydraulic properties to determine the flux (Qm3/d) have been based on the hydraulic conductivity of the clay layer.

Therefore, and using Table 5-2 and using the average flows from Salt Creek (5100 m3/d, refer to EHS Support 2017d); the resulting DAF is 76.7 ((135+5094+5,100+21.4) / 135)

4.2.2 Downward Gradient (Movement from Pit water body to UEVF)

$$DAF = (Q1+ Q2+Q3) / Q1$$

Note: As above, the clay layer present under the pit constrains the flow, the hydraulic properties to determine the flux (Qm3/d) have been based on the hydraulic conductivity of the clay layer. In addition, Q2 assumed a 2000m x 25m cross-sectional area for the Upper Sands of the UEVF.

Therefore, and using Table 5-3 the resulting DAF is 35.2 ((40.5+535.5+850) / 40.5).

Compared to the DAF identified above to achieve the screening level criteria, the criteria are sufficient to ensure no potential impacts on groundwater and surface water. However, despite this, more complex Geochemical Modelling (**EHS Support 2017(i)**) was conducted (refer **Section 5**).

Draft and Confi

4.3 Numerical Modelling Results

The empirical calculations presented in **Section 4.1** are highly simplistic and conservative. Key conservatism inherent in these calculations is that the calculations only consider the upper portions (25m) of the UEVF and does not consider that only the lower portions of the UEVF (~205m in thickness and deeper than the interbedded coal sequences) was historically pumped for groundwater and that the gradients are transient and declining over time.

Numerical modelling presented in EHS Support 2017(e) was used to assess time frames for recharge of groundwater in the area, verify lake fill times and to assess the potential fate and transport of surface water constituents in groundwater via particle tracking. The results concluded that particles of water associated with recharge from the lake into the UEVF does not leave the immediate vicinity of the former pit. Once established seasonal recharge to groundwater and discharge from groundwater into surface water will results in water particles and associated constituents not leaving the area of the pit. Therefore, the empirical calculations provided above are highly conservative and there is limited potential for recharge and migration of particles of water (with potential constituents) into the UEVF. from potential impacts on water quality in the UEVF is considered limited.

A detailed discussion of the model setup and results is provided in EHS Support 2017(e). In addition, geochemical reactions/attenuation occur when the water passes through the ash and the overlying units. This is further discussed in **Section 5**.

Draft and Confidential

5.0 STAGE THREE – GEOCHEMICAL TRANSPORT SIMULATION

While the flux of constituents is a key determinant on potential concentrations in surface water and groundwater (as described above) a number of geochemical reactions will occur as waters mix decreasing (and in rare cases) increasing the solubility of metals in solution. The following section evaluates the geochemical speciation of metals and the possible interactions following mixing with supporting information on geochemical speciation also included in **Attachment 2.**

Geochemical modelling simulations have been used to explore the geochemical characteristics of ash pond water and the interactions that occur when ash pond water mixes with other waters such as UEVF groundwater and the pit water body. The USGS geochemical modelling program PHREEQC has been used in the following sections to explore the speciation and controlling mineral phases that may be present within the ash pond water. The soluble species and mineral phase equilibria will provide information on which species may be mobile or have the potential to precipitate if redox/pH conditions change.

The aqueous and leachable analyses were used in TRANSPORT scenarios between the following solutions and solids:

1. UEVF groundwater, ash porewater and ash solids
2. Pit water body, ash porewater and ash solids

A TRANSPORT and EXCHANGE SURFACE simulation was used to estimate the mass transport of a solution through the ash solids in the pit water body. The direction of flow will either be groundwater from the UEVF aquifer into the pit water body or surface water from the pit water body into the UEVF aquifer (refer to **Figure 5-1**). Both scenarios will be explored. The simulated effluent solutions from each transport scenario will be mixed with solutions representative of the pit water body (scenario 1) and UEVF groundwater (scenario 2). The building of the transport model will use hydraulic parameters defined in the hydrogeological model.

The transport flow pathway is simplified as it does not take into account the clay cover overlying the ash layer or the underlying spoil, residual coal or clay which overlie the UEVF aquifer (refer to **Figure 4-4**). This is a conservative assumption as it does not account for the retardation, attenuation and dispersion that would occur if these materials were included in the transport simulation. They have been omitted due to the level of uncertainty associated with the thickness and physical properties (e.g. CEC, permeability) of these lithologies.

5.1 Development of the transport flow pathway

The simulated transport of UEVF groundwater through a saturated ash lithology has been simulated using the TRANSPORT option within PHREEQC. The setup of the input file has incorporated the attributes of the ash material and the characteristics of the porewater and groundwater solutions. As the groundwater solution flow through the ash, many potential reactions can occur which are illustrated in **Figure 5-1**. Not all of these reactions are accounted for within the geochemical model simulation due to the heterogeneity of the chemical system and limited known characteristics of the pathway.

Draft and Confidential

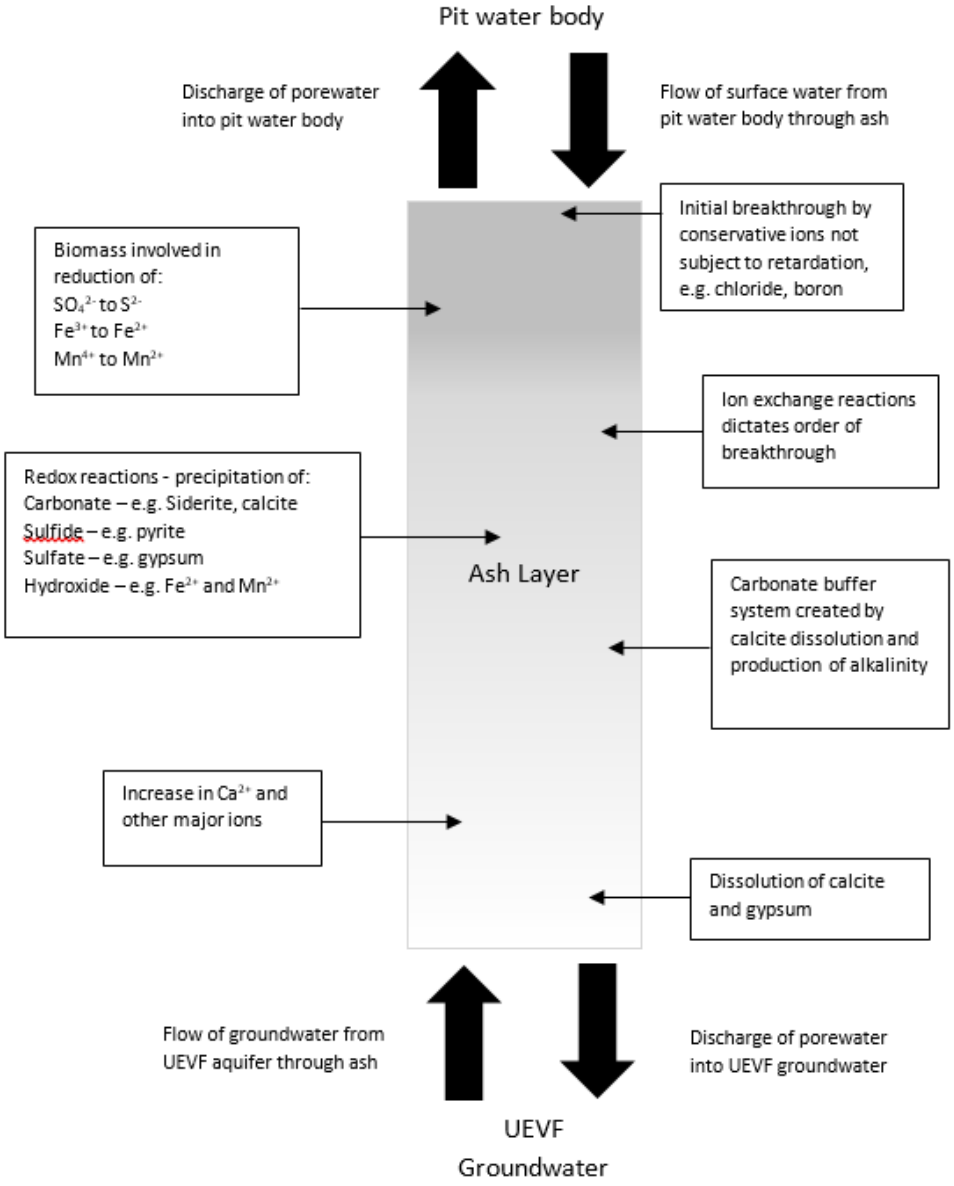

Figure 5-1: Potential reactions occurring along transport flow path

The leachability of compounds within the ash material is dependent on the quantity and acidity of percolating groundwater and on the ion exchange, buffering capacity and redox potential of the ash. For most trace elements leachate concentrations increase with increasing acidity and redox potential. The soluble component of coal ash is dominated by calcium and sulfate and lower concentrations of sodium, potassium and magnesium. Coal ash leachate is alkaline as pH rapidly increases as calcium is leached. Sulfate usually precipitates with calcium as gypsum. If sufficient calcium carbonate is present in the ash, mineral phase precipitation reduces porosity and permeability.

The dry bulk density of the Anglesea power station ash has been reported as 904 kg/m^3 (Beattie, 2003). This is slightly lower than the range of values reported by the EPRI (1993), 1,220±110 kg/m^3 (based on a population of 25). This may be due to the level of compaction which can affect the dry bulk density, in the latter samples. Porosity has not been reported for the ash solids, however, as discussed in **Section 3.2.1.1**, the ash material comprises >70% silt sized particles (2 to 60 µm) and total porosity is anticipated to be elevated. EPRI (1993) report values of total porosity for coal fly ash at 42.3±6.8% (based on a population of 23). Although total porosity is high, effective porosity is expected to be low

Draft

based on the low permeability values. Site specific saturated hydraulic conductivity values are not available, however, EPRI (1993) report 10^{-4} to 10^{-5} m/s. Compacted coal ash typically reports permeabilities within the range 10^{-4} to 10^{-9} m/s dependent on the degree of compaction (EPRI, 1984).

The materials placed in the pit have been hydraulically pumped and allowed to settle and will be subsequently track rolled prior to being covered and on this basis permeabilities are anticipated to be less than 10^{-6} m/s. Effective porosity based on saturated hydraulic conductivity is anticipated to be ≥10% (non-compacted ash) and to decrease over time as mineral precipitation and cementation processes occur within the ash. Compaction of the ash within the pit to achieve a thickness of 2 to 5 m will further reduce the permeability and porosity of the material.

The model input file data blocks discussed below are representative of the final input file structure after a series of development and verification steps which are not presented or discussed.

5.2 UEVF groundwater flow through Ash - Model Input

5.2.1 Transport Solutions

In the transport data block, the flow path has 10 cells, which requires that 10 solutions, 1-10, be defined to infill each cell along the flow path. Solutions 1-10 represent the porewater (or Leachate 1 from the ASLP laboratory analysis). The displacing solution, the UEVF groundwater, is defined as solution 0.

The solution infilling each of the 10 cells of the pathway is defined within SOLUTION 1-10 data block:

```
SOLUTION 1-10 #Leachate 1 ash pond reagent water & ash solids
        Temp            15
        pH              9.8
        pe              0
        redox           pe
        units           mg/l
        density   1
        Alkalinity      116 as Ca.5(CO3).5
        B               29
        Ca              560
        Cl              931
        K               112
        Mg              237
        N(-3)           0.08 as NH4
        Na              1690
        S(6)            4540 as SO4
        -water          1 # kg
```

Figure 5-2: Porewater solution 1-10 data block

As discussed within Attachment 2, the equilibrium phases anticipated to be oversaturated are calcite and gypsum and these are defined as:

```
EQUILIBRIUM_PHASES 1-10
```

Draft and Confidential

```
    Calcite    0 10
    Gypsum  0 10
equilibrate with solution 1-10
```

Figure 5-3: Equilibrium phases 1-10 data block

The influent solution for the initial simulation is defined as the UEVF groundwater:

```
SOLUTION 0 #UEVF groundwater reducing
    temp      15
    pH        6.58
    pe        0
    redox     pe
    units     mg/l
    density   1
    Al        0.05
    N(-3)     0.15 as NH4
    Ba        0.064
    B         0.37
    Ca        86
    Cl        578
    Fe        23.9
    Mg        39
    Mn        0.958
    K         28
    Na        242
    S(6)      146 as SO4
    Alkalinity 103 as Ca.5(CO3).5
    -water    1 # kg
```

Figure 5-4: Influent UEVF groundwater solution data block

5.2.2 Transport Parameters

The PHREEQC transport option has been used to estimate the geochemical changes in ash porewater concentrations as UEVF groundwater flows through an ash horizon. The transport pathway is simulated using a sequential cell arrangement with each cell defined by the physical and hydraulic characteristics of the ash. A solution representative of the ash porewater is equilibrated with equilibrium phases and an exchange assemblage of exchange species which are derived from the analysis of the ash solids:

Draft and Confidential

The composition of the exchange assemblage can be defined in the input file, in two ways:

a) Listing the composition of each exchange component in moles;

```
EXCHANGE 1 ion exchange
    CaX2    0.228
    MgX2    1.246
    NaX     0.205
    KX              0.021
    NH4X    1e-005
    MnX2    1e-005
    FeX2    1e-005
```

Figure 5-5: Exchange data input block, individual exchange species

Or,

b) Specifying that each exchanger is in equilibrium with a solution of fixed composition, used in transport and/or advection simulations (Parkhurst and Appelo, 1999).

```
EXCHANGE 1-4 ion exchange
    X               1.700
   -equilibrate with solution 1
```

Figure 5-6: Exchange data input block, total exchange capacity

The exchanger mean (average) total CEC and individual cation exchange capacity values were converted from meq/100g to moles/L as follows:

The individual species exchange capacity derived as moles/L are calculated by dividing the ash bulk density (0.904 g/cm^3) by the ash effective porosity (0.10) and multiplying by the measured exchange capacity in meq/kg to give meq/L. This value is then divided by the species valance and then by 1000 to correct for units.

Table 5-1: Conversion of average exchange capacity from meq/100g to moles/L

Species	Exchange capacity meq/100g	Exchange capacity meq/kg	Exchange capacity meq/l	Exchange capacity moles/l
Calcium CaX_2	5.0	50.3	455	0.228
Magnesium MgX_2	27.6	275.7	2492	1.246
Sodium NaX	2.3	22.7	204.9	0.205
Potassium KX	0.2	2.3	21.1	0.021
Total X	35.1	351	3173	1.700

Either the total cation exchange or individual exchange values can be used depending on the exchange composition within the model. In **Figure 5-5**, small amounts of ammonium, iron and manganese have been added to provide initial sites for ion exchange of these species. In **Figure 5-6**, the ion exchanger is equilibrated with solution 1, which is the porewater solution.

This keyword data block is used to define a half-reaction and relative log *K* for each exchange species. Normally, this data block is included in the database file and only additions and modifications are included in the input file (Parkhurst and Appelo, 1999).

Draft and Confidential

In the default database file, sodium (NaX) is used as the reference and is the master species, and the reaction X - + Na + = NaX is given a log K of 0.0.

```
EXCHANGE_SPECIES 1-n
    Na+ + X- = NaX
       log_k     0
       -gamma    4 0.075
    K+ + X- = KX
       log_k     0.7
       delta_h   -4.3 kJ
       -gamma    3.5 0.015

       log_k     0.6
       delta_h   7.4 kJ
       -gamma    5.5 0.2
    Mn+2 + 2X- = MnX2
       log_k     0.52
       -gamma    6 0
    Fe+2 + 2X- = FeX2
       log_k     0.44
       -gamma    6 0
```

Figure 5-7: Exchange species input data block

The number of pore volumes required for the simulation defines the number of shifts required. One shift moves a solution to the next cell, and the last solution out of the ash. PHREEQC calculates cell-centred concentrations, so that the concentrations in the last cell arrive 0.5 shifts later at the end of the flow path. The number of pore volumes flushed from the ash is equal to the number of shifts (+ 0.5) divided by the number of cells (Parkhurst and Appelo, 1999).

Table 5-2: Initial PHREEQC transport parameters

Parameter	Value
Pathway length	5 m
Pathway saturated hydraulic conductivity	10^{-5}, 10^{-7}, 10^{-9} m/s
Pathway porosity	0.1, 0.05
Number of cells	10
Length of cell	0.5 m
Number of pore volumes	2
Number of cell shifts along pathway	20

Figure 5-8: Transport data block

For linear flow, which is assumed in the transport simulation, the time step is equal to the cell size divided by the average linear velocity. Based on the range of ash hydraulic conductivities (10^{-5} to 10^{-9} m/sec) sourced from literature (EPRI, 1993) the average linear velocity ranged from 0.864 to $8.6x10^{-5}$ m/day. Although a time duration or time step is assigned to each cell the transport is defined by the number of pore volumes. Reactions are not defined by kinetics or rates but by thermodynamic equilibrium reactions. Therefore, the time step magnitude is meaningless in the geochemical calculations unless rate constants are applied. An estimate of theoretical flow through time can be calculated using the pathway length and hydraulic conductivity. Based on a 5 m pathway length and hydraulic conductivities between 10^{-5} and 10^{-9} m/sec, a conservative transport particle would take between 5.8 days and 57,870 days (or 159 years).

The flow direction is defined as forward advective flow. The boundary conditions are set to flux at the first cell and flux at the end cell. These are the default options. The length for each cell is 1/10th of the total flow path (5 m) which is equal to 0.5 m.

The dispersivity for each cell is 1/10th of the total dispersivity (0.1035 m), which is equal to 0.01035 m. The dispersivity has been estimated by fitting a column breakthrough curve from clay column experimental data, to an analytical solution of the Ogata-Banks advection-dispersion transport equation (Thornton et al, 1993), which is likely to be representative of flow conditions for this transport simulation. The identifier, -correct_disp, should be set to true when modelling outflow from a column set with flux boundary conditions.

The diffusion coefficient is an optional parameter; the default is $0.3e^{-9}$ m^2/s. Model runs were completed with and without this parameter selected. It appeared that the presence or absence in the input file did not make any difference for this specific model setup. The identifiers -punch_cells and -punch frequency, specify that data will be written to the selected-output file for cell 10 at each shift. The identifiers -print_cells and -print_frequency, indicate that data will be written to the output file for cell 10 (the final cell) for every shift.

5.3 UEVF groundwater flow through Ash - Model Output

Results of the simulated flow of UEVF groundwater through saturated ash have been plotted as **Figure** 5-9 to **Figure 5-11**. The estimated concentrations are reported from the final cell of the transport pathway (ash) and does not account for mixing within the pit water body. The influent solution (UEVF groundwater) and porewater within the transport pathway achieve equilibrium within two pore volumes at the highest saturated hydraulic conductivity of 10^{-5} m/sec.

Draft and Confidential

Figure 5-9 plots the change in major ion chemistry of the last cell as 2 pore volumes of UEVF groundwater flow through the ash material. The chemistry of the last cell is constant until approximately 0.75 pore volumes, where the leachate front of the UEVF groundwater starts to influence the decrease in pH. The decrease in pH is observed between 0.75 and 1.15 pore volumes, after which equilibrium conditions are attained within the ash material. The resulting solution which is flowing into the pit water body after 1.15 pore volumes has lower concentrations of sodium and chloride and to a lesser extent calcium, magnesium and potassium and a pH 7.2. Sulfate concentrations are elevated in comparison to the ash porewater, increasing from 2,816 mg/L to 3,086 mg/L. The final concentration is still lower than the initial sulfate concentrations within the unequilibrated ash porewater (4,540 mg/L) due to the initial oversaturation of sulfate.

Alkalinity species and pH change as one pore volume passes through the final cell of the model. As the pH decreases bicarbonate concentrations increase as bicarbonate becomes more dominant than carbonate (refer to **Figure 5-10**). The ash porewater after one pore volume is more circum-neutral (approximately pH 7.2) after the more acidic UEVF groundwater has passed through the ash.

Boron concentrations appear to decrease from 29 mg/L to 0.4 mg/L (refer to **Figure 5-11**) and will be as a result of dilution as boron behaves conservatively. Aluminium was below detection levels in the ASLP results, however, due to the presence of aluminium in the UEVF groundwater concentrations are observed to equilibrate within the ash porewater to 0.05 mg/L. Aluminium is expected to precipitate and the diaspore phase could have been used as an equilibrium phase to simulate this within the initial ash porewater, however, this can only be used if it is initially present as an elemental species. Barium concentrations are also observed to increase from non-detectable concentrations, however, it is likely to form barite (due to elevated sulfate) which is highly insoluble.

Precipitation of gypsum has lowered the sulfate concentrations in the initial equilibrated porewater (refer to **Figure 5-12**). As the UEVF groundwater flows through the ash the pH drops and dissolution of gypsum occurs resulting in an increase in sulfate concentrations. Sulfate concentrations are observed to equilibrate after 1.25 pore volumes while gypsum continues to dissolve. This is due to the supersaturation and potential precipitation of pyrite (iron sulfide). The dissolution of calcite and gypsum has a negligible effect on calcium aqueous concentrations as the additional calcium is taken up by the ion exchange surface.

5.4 Pit water body flow through Ash - Model Input

To explore the potential geochemical changes to pit water body that flows through the ash layer and discharges into the UEVF groundwater a reverse flow scenario was simulated using the transport option within PHREEQC.

5.4.1 Transport Solutions

For the transport data block conditions are maintained as discussed within **Section 5.2.1** for Solutions 1-10 and Equilibrium Phases within the ash flow pathway.

The influent solution for the initial simulation is defined as the pit water body:

```
SOLUTION 0 #Pit water body 080316
   temp      15
   pH        3.1 #CO2(g) -3.5
   pe        4
   redox     pe
   units     mg/l
   density   1
   Al        1.7
   N(-3)     0.53 as NH4
   Ba        0.078
   B         1.1
   Ca        45
   Cl        530
   Fe        14
   Mg        89
   Mn        0.41
   K         9.7
   Na        220
   S(6)      470 as SO4
   Alkalinity 2 as Ca.5(CO3).5
   -water    1 # kg
```

Figure 5-13: Influent pit water body solution data block

5.4.2 Transport Parameters

The majority of the transport data block has been used as discussed within **Section 5.2.2**. The only change was to increase the number of shifts to 200 so 20 pore volumes would be eluted from the column and equilibrium observed in the species of interest.

5.5 Pit water body flow through Ash - Model Output

Results of the simulated flow of pit water body through saturated ash have been plotted as **Figure 5-14** to **Figure 5-17**. The estimated concentrations are reported from the final cell of the transport pathway (ash) and does not account for mixing within the UEVF groundwater. The influent solution (pit water body) and ash porewater within the transport pathway achieve equilibrium (for the majority of species) within twenty pore volumes at the highest saturated hydraulic conductivity of 10^{-5} m/sec.

Figure 5-14 plots the change in major ion chemistry of the last cell as 20 pore volumes of pit water body flow through the ash material. The chemistry of the last cell is constant until approximately 0.75

Draft and Confidential

pore volumes, where the leachate front (consisting of calcium, sodium and sulfate) of the pit water body starts to influence the decrease in pH. The decrease in pH is observed between 0.75 and 1.15 pore volumes, after which equilibrium conditions with respect to pH, are attained within the ash material. Other aqueous species such as calcium, sulfate and sodium do not achieve equilibrium until approximately 20 pore volumes have passed through the ash layer. The varying concentrations are due to equilibrium conditions being established on the ion exchange surface and between defined mineral phases (gypsum and calcite). The resulting solution which is flowing into the UEVF groundwater after 20 pore volumes has a lower pH and elevated concentrations of major ions with the exception of sodium. Eluted sulfate concentrations decrease from 2,816 mg/L in the initial ash porewater to 588 mg/L at the end of 20 pore volumes. The final concentration is higher than the 146 mg/L reported in the UEVF groundwater.

Alkalinity species and pH change as one pore volume passes through the final cell of the model. As the pH decreases bicarbonate concentrations increase as bicarbonate becomes more dominant than carbonate (refer to **Figure 5-15**). The ash porewater after one pore volume is more acidic (approximately pH 5). Dissolution of calcite occurs as the acidic pit water body flows through the alkaline ash material and bicarbonate concentrations are reported at approximately 5,730 mg/L after 20 pore volumes. With bicarbonate and calcium concentrations at these levels, calcite is expected to have precipitated which in reality would result in lower aqueous concentrations of calcium and bicarbonate

Boron concentrations appear to decrease from 29 mg/L to 1.1mg/L, mainly due to the decrease in pH (refer to **Figure 5-16**). Aluminium was below detection levels in the ASLP results, however, due to the presence of aluminium in the pit water body, concentrations are observed to equilibrate within the ash porewater at 1.7 mg/L. Aluminium is expected to precipitate. Barium concentrations are also observed to decrease slightly from 0.064 mg/L to 0.05 mg/L.

Gypsum dissolution at the leachate front is responsible for the initial increase in sulfate concentrations at 0.65 pore volumes (refer to **Figure 5-17**). As the pit water flows through the ash the pH drops and dissolution of gypsum and calcite occurs. Sulfate concentrations are observed to decrease around 1 pore volume and equilibrate after 17 pore volumes while gypsum continues to dissolve. This is due to the supersaturation and potential precipitation of pyrite (iron sulfide). The dissolution of calcite and gypsum appears to have delivered more calcium than can be preferentially exchanged and aqueous calcium is observed to increase as calcite and gypsum dissolve. As equilibrium between calcium, calcite and gypsum is achieved the concentrations level out after 17 pore volumes (refer to **Figure 5-14** and **Figure** 5-17).

5.6 Defining Surface Water and Groundwater Concentrations using Transport Solutions

The chemistry of porewater within the ash material has been predicted using either UEVF groundwater or pit water body as the recharge or discharge solution. The transport simulations do not provide information on chemistry changes once these solutions are discharged into the receiving water. Using the hydrogeologic flux calculations described above, the simple mixing simulations have been revised to incorporate these geochemical processes.

Based on the DAFs calculated above the ash porewater discharge/recharge will be less than 1% to the UEVF and 0.1% to the pit water body during the early time period and once the lake is established the fluxes will be negligible.

5.6.1 Pit water body as a receptor

The simulated chemistry within cell 10 after 2 pore volumes of UEVF groundwater had passed through the ash layer (Section **5.3**) was used to explore the potential changes in chemistry when mixed with the pit water body. This scenario considers upward gradients which result in UEVF moving vertically upward through the ash and into the Pit water body.

At this stage, it is not known precisely what volume to volume ratio of mixing will occur at the interface between discharge of pore water from the ash into the pit water body surface water. Based on the DAFs presented within **Table 4-1** and **Table 6-11**, the ratio of ash pore water moving vertical up into the lake is very small. As noted above, interaction of groundwater with the Ash will not occur until groundwater and levels in the upper portion of the UEVF are at -14 m AHD. Without the diversion of Salt Creek this will not occur for 10 years. Further, the diversion of Salt Creek is planned to occur after completion of toe buttress construction work which will occur in the next year. On this basis, the heads will be downward in the short-term and upward fluxes will only be upward once the lake is full with vertical flux driven solely by evaporation from the lake. As detailed in Section 4 the calculated dilution ratio is 62.80 or a ratio of 0.016 pore water sourced from the ash and 0.984 lake water.

To explore the outcome of larger volumes of ash porewater discharging to the pit water body, a higher magnitude greater than the DAF was used within the mixing ratio (0.05:0.95). Boron and Aluminium are the primary minor ions assessed based on their exceedances of screening criteria. The only significantly measurable change in lake water chemistry is the increase in carbon concentrations (by an order of magnitude). Carbon is not a constituent of concern, does not influence any changes in acidity or alkalinity in the pit water body due to the acidity buffering and is a positive component in supporting various degrees of seasonal mixing (including complete mixing) occurring between the individual layers and establishment of sulfate and metal reduction. For all other constituents, the concentrations are effectively unchanged.

Table 5-3: Results of mixing ratios – Ash Porewater and pit water body

Analyte	Surface Water Background (Salt Creek and Anglesea River)	Ash porewater	Pit water body	0.016:0.984	0.05:0.95
	mg/L	mg/L	mg/L	mg/L	mg/L
pH (unitless)	3.68 – 3.8	7.2	3.1	3.17	3.31
redox (mV)		-177	109	104.42	94.70
Aluminium	9.6 – 52.4	0.05	1.7	1.67	1.62

Draft and Confidential

Analyte	Surface Water Background (Salt Creek and Anglesea River)	Ash porewater	Pit water body	0.016:0.984	0.05:0.95
	mg/L	mg/L	mg/L	mg/L	mg/L
Boron	< 0.05 – 0.30	0.37	1.10	1.09	1.06
Barium		0	0.08	0.08	0.08
Carbon		48	0	0.77	2.40
Calcium		428	45	51.13	64.15
Chloride		581	531	531.80	533.50
Iron	5 – 30	0	14	13.78	13.30
Potassium		98	10	11.41	14.40
Magnesium		185	89	90.54	93.80
Manganese		0	0.5	0.49	0.48
Nitrogen		0.02	0.4	0.39	0.38
Sodium		1,505	220	240.56	284.25
Sulfur	396 – 1,466 (as sulfate)	1,037	157	171.08	201.00

The simulation results suggest that at the anticipated high dilution factors within the pit water body there will be negligible changes to the pit water body chemistry. While Boron is present within the existing pit water body at concentrations greater than background, the Ash water does not yield concentrations significant above background and the surface water into the pit (as part of the rediversion) will result in a decrease in concentrations. Further the short-term treatment activities and the stratification of the lake (with associated biotic processes) will lead to improvements in water quality in the upper lake surface over those calculated above.

5.6.2 UEVF groundwater as a receptor

The simulated chemistry within cell 10 after 20 pore volumes of pit water body had passed through the ash layer (Section 5.5) was used to explore the potential changes in chemistry when associated with the flux of water from the pit water body through the ash into the UEVF groundwater. This scenario reflects the re-diversion of Salt Creek where the elevation of the lake will be higher than groundwater and the lake will be recharge the UEVF.

Using the hydrogeologic evaluation and calculations described above and the resulting DAFs (refer **Table 4-1** and **6-11**), the DAF for flux to UEVF groundwater is 51.44. As detailed above, the numerical modelling indicates that particles of water (and associated constituents) from the pit water body will be confined to the upper portions of the UEVF (the coal sequences) and will not descend into the deeper water bearing layers. Therefore, the calculations provided are considered highly conservative and no additional sensitivity analysis is conducted.

The simulation results suggest that at the anticipated high dilution factors within the UEVF there will be negligible changes to the groundwater chemistry. The only significantly measurable change above that observed naturally in the UEVF is the increase aluminium concentrations from 0.06 mg/L to 0.09 mg/L. Aluminium precipitates at pH greater than 4.5, so is unlikely to be mobile within UEVF groundwater.

Table 5-4: Results of mixing ratios – ash transport porewater and median UEVF groundwater concentrations

Analyte	ANZECC Aquatic or Background	Ash porewater transport outpot water quality	Median Concentrations 1989-2016 UEVF groundwater	mixing ratio 0.03:0.98
	mg/L	mg/L	mg/L	mg/L
pH	3.68 – 3.8	5	5.79	5.15
Redox	not available	-36	0	-40
Aluminium	9.6 – 52.4	1.5	0.14	0.002
Boron	0.37	1.1	0.08	0.11
Barium	not available	0.01	long term data not available	0.0003
Calcium	not available	2,342	long term data not available	72
Carbon	not available	23,986	long term data not available	146
Chloride		531	long term data not available	16
Iron	5 – 30	13.91	long term data not available	0.43
Potassium		167	long term data not available	5
Magnesium	not available	165	long term data not available	5
Manganese	0.1 – 1.9	0.41	0.97	0.95
Nitrogen	0.5	0.18	long term data not available	0.12
Sodium		220	long term data not available	6.8
Sulfur	396 – 1,466 (as sulfate)	374	long term data not available	176

Calcium concentrations are predicted to be higher than the receiving water concentrations, however, as discussed within Section 5.5 calcium is anticipated to precipitate as calcium carbonate. The redox potential is also predicted to be reducing which is being controlled by the precipitation of pyrite.

In summary, the discharge of ash porewater into either the UEVF groundwater or the pit water body is likely to have a negligible effect on the receiving water chemistry.

6.0 CONCLUSIONS

The long-term goal for the rehabilitation of the coal pit void is the creation of a pit water body. Extraction of groundwater in the vicinity of the pit void by Alcoa ceased in early 2016 and the rebound of groundwater levels will gradually flood the pit void. Groundwater and rainfall will contribute to the filling of the pit void which is currently estimated to take between 15-20 years. The slow filling of the pit void increases the risk of acidity generation from materials within the pit void such as overburden and spoil and exposed unworked coal seams within the pit walls. Decommissioning of the former power station facility has included the movement of ash materials from the ash ponds to the eastern area of the pit void.

The surface water catchments and native lithologies surrounding the pit void are characterised by low pH (high acidity) and elevated concentrations of metals such aluminium, iron, manganese and zinc. Depending on the pH, all of these metals have the ability to buffer acidity (through uptake or release of hydrogen ions, H^+). Historically, the pit water body has reported the effects of the dissolution of acidity and metals from the native spoil and overburden within the pit void and the oxidation of elevated iron within the groundwater (which discharges into the pit water body).

During the filling of the pit water body, there is the possibility that recharge of pit water body will occur to the UEVF groundwater. Equally once surface water and groundwater levels have equilibrated UEVF evaporation of water may lead to flux of groundwater through the ash and into the pit water body. Assessment of the potential impacts of the ash on surface water and groundwater quality has been conducted using an assessment of fluxes using hydrogeologic parameters for the site. Simple DAF using the analytical results from ASLP and ash pond water analyses show that there is limited potential for impacts on groundwater quality in the UEVF and the existing pit water body chemistry.

Transport modelling of both pit water body and UEVF groundwater through the ash materials in the pit void has been simulated. Geochemical modelling indicates the porewater and water flowing through the ash solids will attain equilibrium within 2 pore volumes. Using geochemical mixing simulations, the chemical influence of either pit water body or UEVF groundwater on the ash has been evaluated and the resulting changes in receiving water quality. Based on this assessment there was very limited effect on water quality above that observed in the existing pit water body and UEVF. This is mainly due to the dilution effects of the receiving waters but in the case of the pit water body (as a receiving water) acidity buffering limits large increases in pH. In terms of the pit water body chemistry it is recognized that metals are elevated but the lake will be subjected to short-term alkaline additions (which will reduce the solubility of metals) and seasonal stratification, mixing and biological processes.

The simulations provided are considered highly conservative. Based on the referenced hydraulic conductivities of coal combustion ash (10^{-5} and 10^{-9} m/sec), a conservative transport particle would take between 5.8 days and 57,870 days (or 159 years) to travel through the 5m thickness. The geochemical reactions simulated within PHREEQC are based on thermodynamic equilibrium, so it is likely that transport through the ash material would have to be in the order of years or decades for some of the reactions to attain steady-state. Using the equilibrated porewater solutions and receptor waters, the discharge of ash porewater into either the UEVF groundwater or the pit water body is likely to have a negligible effect on the receiving water chemistry.

On the basis of these assessments, the placement and covering of ash with 1 m of silts and clays from the site will provide a solution that will prevent direct interaction of the ash with surface water and is sufficient in combination with the hydraulic properties of the formation to constrain the flux of constituents into groundwater and surface water. Considering these conditions, there will be no long-term adverse impact associated with the placement and management of Ash within the pit.

ATTACHMENT 2 GEOCHEMICAL SPECIATION

Draft and Confidential

GEOCHEMICAL SPECIATION

Geochemical modelling simulations have been used to explore the geochemical characteristics of ash pond water and the interactions that occur when ash pond water mixes with other waters such as UEVF groundwater and pit water body. The USGS geochemical modelling program PHREEQC has been used in the following sections to explore the speciation and controlling mineral phases that may be present within the ash pond water. The soluble species and mineral phase equilibria will provide information on which species may be mobile or have the potential to precipitate if redox/pH conditions change.

Speciation simulations have been undertaken on the following solutions using PHREEQC:

1. Ash pond I water;
2. Leachate from ash solids ALSP;
3. UEVF groundwater; and
4. Pit water body.

Some assumptions were made for the solution input files. Temperature was not collected for this phase of sample collection. A value of 15 °C for the groundwater and surface water is a representative temperature for both systems during the winter months (during which these samples were collected). The temperature is not a sensitive value as the majority of the thermodynamic constants within the database are mostly derived at standard temperature and pressure, i.e. 20 °C and 10^{-5} Pa. Information about potential controlling mineral phases in the UEVF groundwater or ash pond surface water is not available so equilibrium phases were not enabled for speciation. Once the solutions are speciated using PHREEQC, an indication of controlling mineral phases is provided within the output file. These have been used to define the input file for the transport simulations. The PHREEQC or Minteq v4 databases were used for the thermodynamic properties of all input parameters.

Ash pond 1 water speciation

Three water samples were collected for laboratory analysis, the analytical schedule was the same as that used for the UEVF groundwater analysis. The ionic balance of the water samples from locations 1, 2 and 3 was 0.36%, 1.75% and 2.51%. A smaller set of analytes was used for the speciation modelling in PHREEQC which calculated an ionic balance of 0.48%, 2.2% and 3.13% respectively. The analytes used within the PHREEQC input file were compared between the 3 samples. Summary statistics are provided within Table 1.

Draft and Confidential

Median values are not presented; however, they are the same or similar to the mean values. As observed the 3 samples are very similar and the majority of analytes have a limited variance between samples (<10%). One sample (Location 3) is discussed in the following section. A replicate of this sample was used as the reagent water for the second ASLP on the ash sample from Ash Pond 1.

The PHREEQC input file for Location 3 is provided as . Atmospheric partial pressure for carbon dioxide is enabled because the ash pond water is open to the atmosphere. There were no convergence issues encountered within the model and PHREEQC made no adjustments to the charge balance. This indicates that there was low uncertainty with the simulations undertaken by PHREEQC. Ferrous iron was non-detectable within all 3 ash pond samples and no other speciated metals were analysed. Redox couples were not specified for the solutions in PHREEQC, although all solutions were reported to be mildly oxidising.

Figure 1: Solution data input block for ash pond 1 location 3 speciation

Within the output file, PHREEQC predicts the concentration of a range of soluble species based on the parameters within the input file.

Table 2 provides the element input and speciated output for Ash pond surface water at sampling location 3. In contrast to the predicted soluble species within the UEVF groundwater, the ash pond water is dominated by sulfate species influenced by the elevated concentration of sulfate.

Draft and Confidential

Table 2: Ash Pond 1 location 3 - predicted soluble species

Element	Species
Aluminium	$Al(OH)_4^-$
Boron	H_3BO_3
Barium	$BaSO_4$
	Ba^{+2}
Carbon	HCO_3^-
	$MgHCO_3^+$
Calcium	Ca^{+2}
	$CaSO_4$
Chloride	Cl-
Potassium	K^+
Magnesium	Mg^{+2}
	$MgSO_4$
Manganese(II)	Mn^{+2}
	$MnSO_4$
Nitrogen	NH_4^+
Sodium	Na^+
Sulfur	$SO4^{-2}$
	$MgSO_4$

Table 3: Ash pond 1 location 3 predicted oversaturated mineral phases

Mineral phase	Saturation Index (SI)	Mineral Stoichiometry	Primary metal species	Secondary metal species	Primary ligand
Diaspore	2.65	AlOOH	Aluminium		Oxyhydroxide
Gibbsite	1.39	$Al(OH)_3$	Aluminium		Hydroxide
Dolomite	0.8	$CaMg(CO_3)_2$	Calcium	Magnesium	Carbonate
Calcite	0.38	$CaCO_3$	Calcium		Carbonate
Barite	0.35	$BaSO_4$	Barium		Sulfate

A small number of phases are predicted to be oversaturated and with a potential to precipitate. These comprise carbonate, sulfate and hydroxide species which are a function of the pH, oxidising conditions and elevated sulfate concentrations. It is likely that the precipitation is occurring within ash pond 1 and that secondary mineral phases within the ash material include the minerals listed within

. The presence of alkalinity generating mineral phases such as calcite, provide a source of acid neutralisation when the ash is relocated to the Anglesea pit.

Boron is observed to be present as soluble species, with no immobile phases predicted to form. Boron is therefore predicted to be mobile under these geochemical conditions. PHREEQC predicts that there is a potential for aluminium to precipitate as the mineral phase diaspore. To explore the possibility of

Draft and Confidential

this occurring, equilibrium phases is enabled in the input file with diaspore and calcite as mineral phases and pH fixed to 8.22. In the output, it is estimated that less than 99% of the aluminium is precipitated as diaspore with 0.003% or 0.35 µg/L remaining as a soluble species.

Leachate 1 and 2 speciation

The two (2) ASLP leachate analyses were speciated using PHREEQC and the same parameter template input as presented in Section **3.2.3**. The solutions were not equilibrated with atmospheric carbon dioxide because the ASLP was undertaken in sealed containers. There were no convergence issues encountered within the model and PHREEQC made no adjustments to the charge balance. This indicates that there was low uncertainty with the simulations undertaken by PHREEQC.

        S(6)      1500
        Alkalinity        41 #as CaCO3
        -water    1 # kg
```

Figure 2: Solution data input blocks for Ash Pond water and UEVF ASLP results speciation

Table 4 provides the element input and speciated output for both of the leachate solutions. The range of soluble species is virtually the same for both leachate solutions, however, the distribution is different due to the more elevated concentrations within Leachate 1.

Draft and Confidential

Table 4: Leachate solutions 1 and 2 - predicted soluble species

Element	Species
Boron	$H_2BO_3^-$
	H_3BO_3
Carbon	$CaCO_3$
	HCO_3^-
Calcium	Ca^{+2}
	$CaSO_4$
Chloride	Cl-
Potassium	K^+
Magnesium	Mg^{+2}
	$MgSO_4$
Nitrogen	NH_3
	NH_4^+
Sodium	Na^+
Sulfur	$SO4^{-2}$
	$CaSO_4$

Mineral saturation is also similar for both leachate solutions. Calcium carbonate phases dominate with the additional potential for gypsum precipitation. It should be noted that the metals, metalloids and major cations are reported as filtered values and some phases may have been filtered out of the solution prior to the analysis. The absence of aluminium, manganese and iron may be related to precipitation of mineral phases or sorption of complexes to mineral surfaces.

Table 5: ASLP leachate solutions 1 and 2 - predicted oversaturated mineral phases

Solution	Mineral phase	Saturation Index (SI)	Mineral Stoichiometry	Primary metal species	Secondary metal species	Primary ligand
Leachate 1 ash pond reagent water	Dolomite	0.81	CaMg(CO3)2	Calcium	Magnesium	Carbonate
	Calcite	0.49	CaCO3	Calcium		Carbonate
	Aragonite	0.34	CaCO3	Calcium		Carbonate
	Gypsum	0.12	CaSO4:2H2O	Calcium		Sulfate
Leachate 1 UEVF reagent water	Calcite	1.15	CaCO3	Calcium		Carbonate
	Aragonite	1	CaCO3	Calcium		Carbonate
	Dolomite	0.97	CaMg(CO3)2	Calcium	Magnesium	Carbonate
	Gypsum	-0.01	CaSO4:2H2O	Calcium		Sulfate

Boron is observed to present as soluble species, with no immobile phases predicted to form. Boron is therefore predicted to be mobile under these geochemical conditions.

Draft - Confidential

Comparison between Ash Pond water and Leachate 1

As discussed earlier in Section **3.2.2**, the ash pond water has been in contact with the ash solids for an extended period of time and in contact with atmospheric gases such as oxygen and carbon dioxide. The expectation (or hypothesis) is that the chemical composition of the ash pond water is likely to be similar to that of the leachate derived from the ASPL of the ash pond water and the ash solids. To explore this hypothesis, the program AQqa was used to compare the major ion concentrations between the two samples. If the coefficient of variance between the two samples is low (less than 5%), then a good agreement between the samples exists.

Table 6: Comparison of Ash pond location 3 and leachate 1 major ion chemistry

Parameter	Units	Ashpond 1 location 3	Leachate 1 ash pond reagent water	Coefficient ±5%
Calcium	mg/L	450	560	10.89
Magnesium	mg/L	311	237	13.50
Sodium	mg/L	1630	1690	1.81
Potassium	mg/L	102	112	4.67
Bicarbonate	mg/L	63	< 1	NA
Sulfate	mg/L	4340	4540	2.25
Chloride	mg/L	849	931	4.61
Dissolved Solids	mg/L	6080	6140	0.49
Conductivity	µS/cm	9360	9440	0.04
pH	unitless	8.22	9.8	NA

As observed within **Table 6** a reasonable comparison exists between the two solutions, ash pond water (location 3) and leachate 1. Any differences between the two solutions can be attributed to the disequilibrium that potentially exists during the short ASLP test and that the test is not open to atmosphere unlike the ash pond water.

Pit water body speciation

The pit water body has recently been effected by the Ash management activities which have neutralized much of the lake acidity. To facilitate assessment of mixing with pit water body the data from three events including those affected by ash management activities has been utilized to assess the interactions with pit water body that has and has not been amended with alkaline materials. The sample for March 2016 pre-dates the ash management activities that commenced in August 2016 and three samples (one location at three elevations) were collected during ash management activities in October 2016. The October 2016 samples were collected at 0.5 m below surface level (bsl), 4 m bsl and 8 m bsl. As the samples are very similar geochemically only the sample collected from 0.5 m bsl is discussed. The use of pit water body for ash slurrying and re-circulation has altered the water chemistry within the pit water body as detailed within the input files in Table 7. Both sets of samples are discussed below.

Draft and Confidential

Table 7: Solution data input blocks for pit water body speciation

Parameter	Untreated Pit water body 08/03/2016	Treated Pit water body 11/10/2016 0.5 m bsl
Temp	20	20
pH	3.1	6.8
Redox potential	4	4
Density	1	1
Al	1.7	0.18
B	1.1	4.01
Ba	0.078	0.037
Ca	45	294
Cl	550	480
Cu	0.0005	0.0005
Fe	14	0.5
K	9.7	25
Mg	89	59
Mn	0.52	0.143
Na	220	389
Ni	0.028	0.007
Zn	0.1	0.012
S(6)	470	1180

The acidic pH of the pit water body suggests that equilibrium conditions between jarosite (yellow boy) and ferrihydrite/goethite (equilibrium at pH 3.2) could be present (Miller, 1979). The oxidation of pyrite has multiple intermediate stages with the formation of a variety of ferric/ferrous hydroxysulfates minerals including jarosite. Jarosite is a fully oxidised (ferric) iron hydroxysulfate mineral which is stable at low pH. It also has retained or latent acidity which can be generated under increasing pH. Jarosite weathers to ferrihydrite or goethite which are both ferric oxyhydroxides. The buffer system created between jarosite and ferrihydrite has the capacity to buffer large amounts of added alkalinity which means it is critical that acidity budgets are calculated taking actual and retained acidity into consideration.

As observed within **Table 7**, the pit water body quality is markedly different before and during the ash management activities. In particular, pH increases by three pH units, dissolved metal concentrations decrease (e.g. aluminium, iron, manganese and zinc) and boron and calcium concentrations increase. These changes are mainly due to the increased alkalinity of the ash pond water mixing with the pit water body which increases the pH and decreases the solubility of metals. The March 2016 sample speciation also reports the majority of mineral phases as unsaturated. Only barium sulfate was slightly oversaturated. The October 2016 samples predict iron and aluminium mineral phases as approaching saturation or oversaturated which could account for the decrease in the concentrations of these metals between March and October 2016 (**Table 8**). Other metal decreases (manganese and zinc) could be related to co-precipitation and/or sorption onto precipitating mineral phases.

Draft and Confidential

Table 8: Comparison of pit water body before and during ash management activities

Location	Date	Depth	Mineral phase	Saturation Index (SI)	Mineral Stoichiometry
Pit water body	08/03/2016	surface	Barite	0.65	BaSO4
			Diaspore	-3.11	AlOOH
			Magnetite	-9.65	Fe3O4
	11/10/2016	0.5 m bsl	Barite	0.49	BaSO4
			Diaspore	3.86	AlOOH
			Magnetite	15.26	Fe3O4
		4 m bsl	Barite	0.5	BaSO4
			Diaspore	4.05	AlOOH
			Magnetite	15.38	Fe3O4
		8 m bsl	Barite	0.45	BaSO4
			Diaspore	3.89	AlOOH
			Magnetite	15.31	Fe3O4

For all following mixing and transport scenarios the pit water body sample dated 08/03/2016 will be used as this is representative of historical water quality and closest to equilibrium conditions.

Executive summary

This report is subject to, and must be read in conjunction with, the limitations set out in sections 2.3, 2.2.2, and the assumptions and qualifications contained throughout the Report.

Barwon Water investigated and developed the Anglesea borefield, an urban groundwater supply, between 2007 and 2010 in response to severe water shortages at that time. The borefield is one of a number of water sources that can be used by Barwon Water to supplement the existing Greater Geelong water supply system. Barwon Water's diverse water supply mix is part of a balanced approach to managing the region's water resources and providing greater water security. Development of the borefield was supported by a series of field and desktop investigations, including numerical modelling of potential borefield impacts by GHD (the "Anglesea groundwater model"). A Bulk Entitlement (BE) for borefield operation was originally issued by the Victorian Government in June 2009 based on those preliminary investigations and updated in 2014 following a 6-month pumping test and further calibration of the numerical model. Five-yearly review of data and modelling is required under the BE following borefield operation, which occurred in late 2019, and Barwon Water rely on the model for borefield sustainability and impact assessments.

Alcoa of Australia Ltd (Alcoa) developed and operated the Anglesea open cut coal mine and power station from the 1960s through to 2015. This involved abstraction of up to 4 GL/year of groundwater for water supply. Mine operations ceased in August 2015, after which site rehabilitation activities began, including the development of a pit water body. These activities are ongoing.

In 2020, Alcoa applied to Southern Rural Water (SRW) to amend their existing groundwater abstraction licence to enable completion of a 12-month pumping test. This test is designed to assess the sustainability and effects of groundwater abstraction for filling of the pit water body over a period of approximately ten years (EHS, 2020). Hydrogeological data from the test will support further development and calibration of a numerical groundwater model to establish a sustainable abstraction rate. The first 6-month period of the proposed 12-month test commenced on the 13th of May 2021, and ceased in December 2021. A second period of test pumping was conducted by Barwon Water using its Anglesea Borefield, between January and July of 2022.

An agreement was reached between Barwon Water and Alcoa for Alcoa to utilise Barwon Water's Anglesea groundwater model, updated using data from Alcoa and Barwon Water, to support Alcoa's license application to SRW for potential long-term groundwater abstraction. The data collected as part of the Alcoa pumping test has been used to inform the update of this groundwater model.

The intention is to develop a single Anglesea groundwater model that is suitable for both Barwon Water and Alcoa's ongoing water management and planning needs. This will be an updated groundwater flow model based on the earlier model of GHD (2013), but utilising the comprehensive post-Alcoa closure observation data, including the recent test pumping data.

The updated Anglesea groundwater model is the subject of this report.

The broad objectives of the developed groundwater model are two-pronged:

- Support Barwon Water's Anglesea borefield planning, management and approvals works under the BE process.
    - Specifically, Barwon Water are required to periodically update their groundwater flow model that underpins the Anglesea borefield Bulk Entitlement and use it to re-assess aspects of borefield sustainability, details of which are outlined in the main body of this report.
    - It is intended that GHD, with subconsultant Groundwater Logic, will, after the work documented in this report, develop, and apply predictive model scenarios for Barwon Water's purposes, using the developed history-matched models documented in this report.
- Support Alcoa / EHS Support (EHS) for Alcoa's mine closure and rehabilitation planning and management works.

- Specifically, support Alcoa's license application to SRW for potential long-term groundwater abstraction for filling of the pit water body. Specific issues to be addressed using the model are outlined in the main body of this report.
- It is intended that Alcoa/EHS will develop and apply predictive model scenarios for Alcoa's purposes, using history-matched models developed by GHD.

Existing hydrological conditions and conceptualisation of the groundwater and surface water systems that underpin development of the numerical model are summarised in the main body of this report.

The developed model is based in a minor sense on the earlier modelling of GHD (2013) but is a wholly new model using a new numerical code, new layer structure, new parameterisation schemes, and modern methods of history-matching to historical observation data. It was built and operates in a stochastic framework that recognises input observation data and model parameter uncertainties.

The intent of using this approach is that the recognised input uncertainties are carried through to their effects on model forecasts and their uncertainty, and therefore their effects on water management decision-making.

The model simulates flux-conserved groundwater and surface water flow, and interactions between the two systems. It also simulates the post-Alcoa coal mine closure pit water body balance, including its interaction with groundwater and other surface water systems. The model history-matching process therefore uses a range of surface water and groundwater data of wide-ranging types, including pit water body water levels, to inform (constrain) model parameters. It also uses derivative observations such as watertable depth-frequency curves, flow-frequency curves, pumping-induced drawdown trends, and vertical hydraulic gradients.

The intent of employing these wide-ranging observation types is, to the extent possible, minimise related model forecast uncertainties, such as the uncertainty in potential effects from groundwater use on the shallow watertable (in swamps), surface water systems, and acid generation risks.

263 history matched model realisations, each with widely varying parameters, were selected from an ensemble of 500. For predictive scenario modelling purposes, a smaller, more manageable number of model realisations will be selected for application in that case (e.g., the top 150 models of higher history match quality).

History match quality across these models is generally good, for groundwater levels in deeper bores, watertable depths in shallow bores, pit water body levels, and surface water flows. However, there are of course exceptions to this, which are discussed in the main body of this report. Several points for further investigation and analysis - aimed at improving history-match quality at specific sites in specific ways - are also identified and discussed.

The model developed, and framework used, provide a sound basis for ongoing use of the model in the context of rigorous model forecast and uncertainty assessment for both Barwon Water's and Alcoa's unique requirements.

1. Introduction

Barwon Water investigated and developed the Anglesea borefield, an urban groundwater supply, between 2007 and 2010 in response to severe water shortages at that time. The borefield is one of a number of water sources that can be used by Barwon Water to supplement the existing Greater Geelong water supply system. Barwon Water's diverse water supply mix is part of a balanced approach to managing the region's water resources and providing greater water security. Development of the borefield was supported by a series of field and desktop investigations, including numerical modelling of potential borefield impacts by GHD (the "Anglesea groundwater model"). A Bulk Entitlement (BE) for borefield operation was originally issued by the Victorian Government in June 2009 based on those preliminary investigations and updated in 2014 following a 6-month pumping test and further calibration of the numerical model. A five-yearly review of data and modelling is required under the BE following borefield operation, which occurred in late 2019, and Barwon Water rely on the model for borefield sustainability and impact assessments.

Alcoa of Australia Ltd (Alcoa) developed and operated the Anglesea open cut coal mine and power station from the 1960s through to 2015. This involved abstraction of up to 4 GL/year of groundwater for water supply. Mine operations ceased in August 2015, after which site rehabilitation activities began, including the development of a pit water body. These activities are ongoing.

During 2020, Alcoa applied to Southern Rural Water (SRW) to amend their existing groundwater abstraction licence to enable completion of a 12-month pumping test. This test is designed to assess the sustainability and effects of groundwater abstraction for filling of the pit water body over a period of time (EHS, 2020). The first 6-month period of the 12-month test commenced on the 13th of May 2021. Ultimately the second 6-month period was not completed by Alcoa. Barwon Water also undertook a 6- month pumping trial, starting in January 2022, and utilising all 7 of their production bores in the Anglesea borefield. Hydrogeological data from both the tests will support further development and calibration of a numerical groundwater model to establish a sustainable abstraction rates from the target aquifer systems. An agreement was reached between Barwon Water and Alcoa for Alcoa to utilise Barwon Water's Anglesea groundwater model, updated using data from Alcoa and Barwon Water, to support Alcoa's license application to SRW for potential long-term groundwater abstraction. The data collected as part of both Alcoa's and Barwon Water's pumping tests has been used to inform the update of this groundwater model.

1.1 Purpose of this report

The purpose of this report is to document the design, development, and history-matching of a numerical groundwater flow model of the Anglesea area and surrounds. The purpose of this modelling is two-pronged:

- To support Barwon Water's Anglesea borefield planning, management and approvals works under the BE process.
    - Specifically, Barwon Water are required to periodically update their groundwater flow model that underpins the Anglesea borefield Bulk Entitlement and use it to re-assess aspects of borefield sustainability, details of which are outlined in the main body of this report.
- To support Alcoa / EHS Support (EHS) for Alcoa's mine closure and rehabilitation planning and management works.
    - Specifically, support Alcoa's potential license application to SRW for potential long-term groundwater abstraction for filling of the pit water body. Specific issues to be addressed using the model are outlined in the main body of this report.

The intention is to develop a single Anglesea groundwater model that is suitable for both Barwon Water and Alcoa's ongoing water management and planning needs. This will be an updated groundwater flow model based on the earlier model of GHD (2013). The updated Anglesea groundwater model is the subject of this report. The specific objectives of the updated model are detailed in Section 2.1.

It is intended that Alcoa/EHS will use the GHD-developed groundwater model to apply predictive model scenarios for Alcoa's mine closure and rehabilitation planning and management purposes after the model development documented in this report is complete. Similarly, it is intended that GHD, with subconsultant Groundwater Logic, will, after the work documented in this report, develop, and apply predictive model scenarios for Barwon Water's BE review purposes, using the developed history-matched models documented in this report.

1.2 Scope

The scope of work documented through this report is to re-develop the Anglesea groundwater model to the point of history matching (i.e., excluding scenario forecasting). Scope items include:

- Migrate model software from MODFLOW-SURFACT to MODFLOW-USG-Transport, or possibly MODFLOW 6.
- Develop a new grid or mesh with spatial refinement around key features of interest.
- Capabilities are to remain as per the current model: i.e., detailed semi-integrated simulation of groundwater and creek and river flows, and interaction of both systems with a pit water body.
- Update model layers and structure in consideration of more detailed data and requirements around the Anglesea coal mine pit water body.
- Extend the previously applied PERFECT (Littleboy et al., 1989) recharge/runoff model (or similarly capable tool) in time and integrate its outputs with the revised model code and mesh.
- Rebuild all model boundary conditions (coastal, creeks and rivers, groundwater users' wells, Alcoa's pit water body).
- Undertake model history-matching to all relevant available data, including Alcoa's (2021) and Barwon Water's (2022) pumping tests.
- Include assessment of model uncertainty in the history-matching process.
- Document the project and model objectives, design, build and history-matching outcomes.
- Hand over the groundwater model to Alcoa/EHS for their use in model scenario forecasting to meet Alcoa's specific project objectives.
    - This will include a base forecast model template for Alcoa/EHS to modify and further develop as needed.
- Contribute to the Technical Reference Panel (TRP) review process as needed.

The scope of work excludes the following:

- No scenario modelling or development of results for such modelling to be conducted or reported at this stage.
- Conceptual Hydrogeological Model as relevant to Alcoa and EHS is to be developed and documented by Alcoa/EHS.

1.3 Limitations

This report: has been prepared by GHD for Barwon Water and may only be used and relied on by Barwon Water for the purpose agreed between GHD and Barwon Water as set out in sections 1.1 and 1.2 of this report, and in accordance with the terms and conditions. In addition, it may only be used by Alcoa in accordance with Data Sharing Agreement between Barwon Water and Alcoa (dated 28th October 2021).

GHD otherwise disclaims responsibility to any person other than Barwon Water arising in connection with this report. GHD also excludes implied warranties and conditions, to the extent legally permissible.

The services undertaken by GHD in connection with preparing this report were limited to those specifically detailed in the report and are subject to the scope limitations set out in the report

The opinions, conclusions and any recommendations in this report are based on conditions encountered and information reviewed at the date of preparation of the report. GHD has no responsibility or obligation to update this report to account for events or changes occurring subsequent to the date that the report was prepared.

The opinions, conclusions and any recommendations in this report are based on assumptions made by GHD described in this report (refer section 2.3 and other various sections), and subject to the model limitations as described in this report (refer section 2.2.2 and other various sections of the report) . GHD disclaims liability arising from any of the assumptions being incorrect.

2. Model Objectives & Approach

2.1 Objectives

The broad objectives of the developed groundwater model are two-pronged:

- Support Barwon Water's Anglesea borefield planning, management and approvals works under the BE process.
    - Specifically, Barwon Water are required to periodically update their groundwater flow model that underpins the Anglesea borefield Bulk Entitlement and use it to re-assess aspects of borefield sustainability (Table 2-1).
    - It is intended that GHD, with subconsultant Groundwater Logic, will, after the work documented in this report, develop, and apply predictive model scenarios for Barwon Water's purposes, using the developed history-matched models documented in this report.
- Support Alcoa / EHS for Alcoa's mine closure and rehabilitation planning and management works.
    - Specifically, support Alcoa's potential groundwater licence application for utilising groundwater sourced from the Upper Eastern View Formation (UEVF) aquifer for filling of the pit water body. Specific issues to be addressed using the model are outlined in Table 2-1.
    - It is intended that EHS will develop and apply predictive model scenarios for Alcoa's purposes, using history-matched models developed by GHD.

Since the Anglesea groundwater model last underwent a major update (GHD, 2013), a much more extensive body of groundwater and surface water data has been collected than was available in 2013. Furthermore, major hydrological changes have occurred – specifically Alcoa ceasing operations and groundwater abstraction, paired with the development of a pit water body. This aquifer stress-response data, in conjunction with data from the recent 6-month pumping test, provide a strong basis for constraining model parameters and therefore the uncertainty of forecasts related to those stresses.

It is sometimes said that developing a model aimed at covering many different issues is not a good idea. In this case however, the nature of the groundwater and surface water systems utilised and potentially impacted by the two parties (Alcoa and Barwon Water), and their interconnections, support this broad approach for many objectives. This does not mean however that the model should aim to "do everything"; certain requirements will be better addressed through more targeted tools.

Table 2-1 Anglesea Groundwater Model Objectives of Barwon Water and Alcoa

Party	Item	Requirement	Required model features
Barwon Water	1	Sustainability of the Anglesea borefield in terms of long-term recharge (climate and other) risks, and specifically available production bore pressures.	A method of estimating the nature, timing, and magnitude of groundwater recharge, such as a physically based recharge-runoff model.
	2	Spatial drawdown impacts (in all aquifers) of pumping groundwater from the Anglesea borefield (i.e., from the Lower Eastern View Formation (LEVF))	3D groundwater flow model covering all forecast-relevant aquifers and aquitards.
	3	Impacts of borefield use on Bulk Entitlement "trigger bores" - including in the swamp/alluvial aquifer (ASA)	– Simulation of the alluvial swamp aquifer watertable, and interaction with intermittently through-flowing creeks and rivers. – Simulation of intermittent flows and flow losses and gains to/from the watertable. – Simulation of the frequency and duration of creek flows (and swamp outflows), and periods of shallower versus deeper swamp watertable. I.e., periodic flushing of the swamp watertable. – And as per [1] above.
	4	Impacts of borefield use on creek flows, specifically low flows and flow frequencies along the Anglesea River, Salt Creek, and all tributaries.	
	5	Impacts and risks from borefield use on acid-generating potential from the Swamp/Alluvial Aquifer (ASA), and ultimately creeks and rivers.	
	6	Risks of borefield use from coastal saline intrusion.	Simulation of drawdown along coastal areas, and suitable simulation of the coastal margin in the groundwater model.
	7	Risks of borefield use on pumped LEVF groundwater quality (primarily TDS).	Simulation of Upper, Middle and Lower Eastern View Formation (UEVF, MEVF and LEVF) aquifers/aquitards at a minimum. A simple mixing model based on fluxes between these is used.
	8	Risks of Alcoa's rehabilitation works on groundwater quality and quantity recoverable from the Anglesea borefield, and on sustainability questions asked of Barwon Water's borefield use.	Simulation of the Alcoa pit water body, and its development over time. This includes augmentation options such as creek diversion, and augmentation from groundwater. It must also include interactions with the underlying groundwater system, and inflowing and outflowing surface waters.
	9	Risks of borefield use on land subsidence.	Ability to estimate drawdown across the entire onshore aquifer area. Subsidence will be assessed using these model outputs by suitably qualified geotechnical engineers and using a simple 1-D subsidence model.
	10	Risks of borefield use to third party groundwater users in all aquifers.	
Alcoa	11	The hydraulic impact zone (HIZ) i.e., the cone of depression caused by pumping groundwater at various rates from an existing production bore (likely WB16).	As per [2] above
	12	Groundwater drawdown at various locations due to pumping: – Other groundwater users – Within the in-pit power station waste ash deposit – At the coast and at the base of the Anglesea Estuary (for saline intrusion risk) – In the perched swamp watertable – At BW BE trigger bores – At BW production bores	As per [2,3,5,6,10] above

Party	Item	Requirement	Required model features
	13	The potential water quality impact zone (WQIZ), i.e., pit water migrating into groundwater, both horizontally and vertically under various scenarios including: – Pumping the lower sands of the UEVF to accelerate filling the void. – Using supplemental Salt Creek flows (or other surface water) to fill the void.	As per [8] above
	14	Estimate groundwater recovery times and likely steady state level water level within the mine void and surrounding aquifer, under various scenarios of augmented filling.	As per [8] and [2] above
	15	Maximum extent of pit water body water migration into the groundwater system	Particle tracking (e.g., Mod-Path3DU) or flux source tracing (e.g., FlowSource code (Foley and Black, 2013))
	16	What a particle of water does where Alcoa have covered the power station waste ash deposit (in-pit near MB4) once that becomes submerged beneath the pit water body.	As per [15] above
	17	Impact of pumping on creek and river flows	As per [4] above

In summary, the following features are therefore required of the groundwater model:

- Regional groundwater flow simulation covering the ASA, UEVF, MEVF, LEVF at a minimum.
- Dynamic simulation of groundwater recharge under climate variability.
- Dynamic simulation of creek flows, their variability, and interactions with the groundwater system.
- Dynamic simulation of the Alcoa pit water body water balance and water levels, and pit water body interactions with groundwater and surface water systems.
- Groundwater particle tracking and/or flux source tracing in the vicinity of the pit water body and Alcoa production bore(s).
- Simulation of groundwater pressure changes along the coast, for saline intrusion risk assessment.
- Simulation of dynamic watertable variability in the ASA, for use as a proxy measure of acid generation risk across model scenarios.
- Simulation of groundwater pressure drawdown at third party users' bores.
- Sensitivity assessment of climate change effects on key forecasts of interest. This should focus on potential future sea level rise, changes to groundwater recharge rates, and changes in evaporation, particularly as that relates to the simulated future pit water body.

Given modern industry standards, and the requirements of the Department of Energy, Environment and Climate Action's (DEECA's)[1] Technical Review Panel (TRP), the developed model must be capable of simulating these objectives using methods that recognise and account for model uncertainty, and potentially conceptual uncertainty.

2.2 Approach

The broad approach to the modelling documented in this report is centred around assimilation of as much data of relevance to the required forecasts of interest (Table 2-1) as is possible; see Section 5.2 for details. This is implemented in a framework that recognises model input and process representation uncertainties in such a way that they are carried through to their effects on model forecasts and their uncertainty (see Sections 5 and 6, particularly Sections 5.1, 5.2.1, 5.3 and 6.1.7).

Existing hydrological conditions and conceptualisation of the groundwater systems that underpin development of the numerical model are described in separate reports and are not duplicated herein (see: EHS, 2022a; GHD, 2013; GHD, 2019). Nonetheless, key aspects of the hydrogeological conceptualisation and underlying data are described where relevant for supporting model design and performance.

[1] Formerly known as Department of Environment, Land, Water and Planning (DELWP)

2.2.1 How will acid generation risks be addressed through modelling?

The BE review process, largely centring around review of GHD (2013), noted that little was known about acid generation processes, and hence the assessment of acid generation risks from groundwater development was very uncertain (DELWP, 2013). GHD (2013a and 2013b) identified Salt Creek as the dominant source of acid generation events in the Anglesea catchment, based on previous studies, and analysis of recent creek flow and groundwater level data, as compared with the historical record of acid generation events. GHD (2013a) also developed conceptual models of acid generation but highlight significant knowledge gaps towards which more recent efforts have been directed at addressing (e.g., Monash University (2020)).

GHD (2013a) describe a 2-layer (vadose and saturated zone) acid generation model, the boundary between which varies through time in response to climate and potentially other factors such as vegetation water use, stream flow, and groundwater pumping. This work was supported by a preliminary Acid Sulphate Soil (ASS) assessment undertaken at two locations within the Anglesea swamp by Glover and Webb, 2013. Monash University (2020) subsequently investigated the distribution and characterisation of acid sulphate soils in the Anglesea swamplands for Barwon Water.

The GHD (2013a) model, supported by the more recent work of Monash University (2020), is that sulphide-bearing sediments, peat, and coal are exposed to air and oxidised in the vadose zone. This primarily occurs during dry spells when the watertable falls, exposing sulphidic material in previously oxygen-poor (saturated) conditions to air. In subsequent wet periods, these newly oxidised sediments and coal are rewet, completing the oxidisation process, acidifying infiltrating water and runoff. This leached acid, and potentially metals along with it, is mobilised into runoff, interflow[2], and recharge to the watertable.

Monash University (2020) found that:

- Both Salt Creek and the Marshy Creek (upper Anglesea River) contain substantial volumes of acidity in a form that can be mobilised rapidly.
- Marshy Creek contains higher concentrations of “labile” acidity that can be readily mobilised than Salt Creek, although Salt Creek contains higher concentrations of “retained acidity” that can be slowly released over time.
- Greater evidence of previous sulphide oxidisation (i.e., less labile acidity) identified in Salt Creek Swamplands. The values are high enough to suggest significant historical oxidation in Salt Creek which may be more extensive than what has occurred at Marshy Creek.
- There is 2.4 times higher net acidity in the surface 0-10 cm of soil in the Salt Creek Swamplands than in the Marshy Creek Swamplands.

GHD (2013a) point out many variables that may influence the timing, magnitude, and location of acid generation events. A key driver is the frequency, intensity, and duration of wet versus dry climate spells. Clearly, longer, more intense dry spells incur a lower watertable over a longer duration, and less flushing of sulphidic material from the vadose zone - hence driving a greater potential for oxidisation and therefore acid generation in subsequent wet spells. Acid may also be mobilised (by runoff and interflow) and transported from upper-catchment areas to lower catchment areas, such as the Anglesea swamplands, where they may accumulate and be later flushed out. Other factors such as topographic position and form, and small-scale sediment property variability contribute to where acid generation processes are most likely to occur.

[2] Deep soil drainage diverted laterally to streams by low permeability sedimentary horizons, rather than passing vertically down to the watertable.

In the Anglesea swamplands, GHD (2013a and 2013b) suggest that acidic outflows from the swamp periodically occur during wet climatic events, when the watertable has risen sufficiently high over sufficiently broad an area that stream discharge occurs out of the swamp, ultimately into the Anglesea Estuary. During these events, more potentially acid-containing baseflow and stream flow passes through to the catchment outlet than would be the case during smaller rainfall and flow events. That stream flow reaching the catchment outlet carries with it significant volumes of groundwater baseflow (much of it from the acid generating portions of the swamp sediments), because the watertable is shallower across larger catchment areas, driving higher rates of groundwater baseflow over longer reaches of stream. It will also carry with it large volumes of runoff and interflow which would also carry with it mobilised acid and metals similarly flushed from the vadose zone and shallow surface soils.

Historical observations suggest that the longer the preceding dry spell, the more significant the subsequent acid generation event (GHD, 2013b). Such swamp flushing events, particularly in Salt Creek, are known to have periodically caused “fish kills” in the estuary (see GHD, 2013b Section 3.3). GHD (2013b) concluded that “*fish kill events may potentially occur when Salt Creek has had no significant outflows (i.e., >1 ML/day) for greater than 15 months, and this low-flow period is followed by a first flush event of greater than 4-5 ML/day*”.

A more detailed updated conceptual model of acid generation events is described in EHS (2022a) and Section 3.10.1.2.

Simulation of physico-chemical acid generation processes using the groundwater model is computationally impractical and probably futile given the paucity of supporting data and extremely wide variation in acid generating process throughout the catchment (see GHD, 2013a). As a more practical alternative, it is proposed to use proxy hydraulic measures of scenario-induced change to acid generating processes. As such, the modelling of this report will be designed as follows:

- Simulate seasonal and inter-annual recharge, potential groundwater evapotranspiration, and interflow/runoff dynamics using a soil water balance model (see Section 4.5.5).
- Simulate the intermittent nature of streams using the Stream Flow Routing (SFR) package (see Section 4.5.8). This includes the ability to simulate:
    - Complete loss of stream flow routed from catchment headwaters before it reaches the catchment outlet during dry spells.
    - The enhanced passage of stream flow from headwaters to the catchment outlet during wetter climatic spells.
    - Variable baseflow-gaining / stream flow-losing conditions along streams through time.
- Simulate the watertable within swamp sediments using a single model layer, which enables simulation of variable saturated/vadose zone depths over time. The aim is to simulate watertable dynamics and its interaction with overlying streams.
- Watertable and stream flow dynamics, and how they change under simulated groundwater development scenarios, are the adopted proxy measures for acid generation risk. This risk will be assessed in response to groundwater development scenarios in the following ways:
    - Watertable depth-duration/frequency curves.
    - Maps of watertable variability, and scenario-induced change in that variability.
    - Stream flow duration/frequency curves.
    - No flow period statistics.

That is, scenario-induced change to the processes driving the risk of acid generation in the catchment will be assessed using the above proxy indicators. For example, should a groundwater development scenario result in significant increases in the frequency and duration of zero stream flow and/or deeper watertable events, this would imply an increased risk of acid generation events. This information could potentially be used in a more detailed assessment of acid generation in the catchments. For example, in the event of an inferred high risk, a specific acid generation / geochemical model could be developed.

Uncertainty in these measures and the implied risks will be assessed using the stochastic modelling framework described in Section 5.1. This will be supported by the inclusion of observations of direct relevance to the acid generating processes described above in the history-matching process (Section 5) – specifically spatio-temporal variability in swamp watertable depths and stream flows.

2.2.2 Toward addressing previously identified model limitations

GHD (2019) outlined fourteen limitations of the model upon which this report's model will be based. Not all of these can be addressed because they relate to inherent limitations of groundwater modelling and simplified representation of geological variability. However, some of those limitations can be addressed or at least further investigated through the work of this report. These are outlined in Table 2-2.

Table 2-2 Previously Identified Model Limitations and Proposed Redress

Issue	Description (GHD (2019))	Propose to address in updated model
1	Outcrop area of the LEVF in the northwest area and outcrop of MEVF to the south. The best interpretations have been made on the available data. Significant uncertainties remain, despite further sampling and palynological analysis having been undertaken to improve the definition of this outcrop region;	The proposed modelling approach will employ spatial parameter variability using pilot points, with allowable upper and lower bounds reflective of the uncertainty in the properties of each unit, so that they can play proxy hydrogeological roles in different areas as driven by the observation data. See Section 5.3. Actual layer extents / outcrops cannot be allowed to vary in the model history matching process as designed, and so some limitations in this regard remain unresolved.
2	Thickness and extent of all geological units. This has been based upon point borehole information, which is sparse for many of the geological units across many areas of the model domain. The point data have been interpolated using geological judgement and is therefore likely be incorrect in places. The geological model used in this report was updated from earlier models, but the model recalibration suggests that there remain significant shortcomings, primarily related to the role of geological structure in aquifer boundary effects;	As per [1]. In addition, model layering is enhanced locally to the Alcoa mine through the mapping of EHS (2022a), which is carried through to the updated model layering (Section 4.3). Uncertainties in the role of geological structure, although not having been investigated further since the work of GHD (2013), can also be addressed to some degree using finer resolution spatial parameter variability in the model than was employed by GHD (2013), and definition of suitably wide allowable parameter bounds (Section 5.3). This will enable (for example) the barrier role of a fault zone to be mimicked through lower hydraulic conductivity interpolation where the observation data suggests such features may exist. Where the data do not imply such a feature's existence, yet it exists, the model uncertainty analysis would allow parameters to take on any value within the allowable bounds, thereby incorporating these potential effects in an indirect manner. However, given historical stresses (at least in the UEVF) are greater than those proposed in future, this issue is unlikely to be of significance to model forecasts.
3	Simulation of Geological Heterogeneity. Geological and hydrogeological structure has been simplified down to only 7 layers. These aquifers comprise many sub-units with different pressures and behaviours. The numerical model is unable to simulate such detail, nor are the data available to support such a simulation. This has the potential to prove a shortcoming of model forecasts;	As per [1] and [2]. However, it must be noted that the true hydrostratigraphic complexity is infinite and cannot ever be modelled. Simplifying assumptions are an inherent feature of modelling, and so limitation remain in this regard.
4	Lateral facies changes in the UEVF main coal deposit. The model simulates the extent of this geological unit based upon mapping of the coal. The modelled extent of the UEVF main coal deposit aquitard may be significantly smaller than the aquitard really is. This in turn will result in the model over-predicting drawdown and baseflow impacts on surface water features, particularly the impacts predicted for Anglesea Swamp.	As per [1]; model layers within the Alcoa area of interest have been updated with far greater detail than in the model of GHD (2013). In addition, pilot point parameterisation and suitably wide allowable bounds will allow the model history-matching and uncertainty analysis process to mimic facies changes. See Section 4.3 and 5.3.

Issue	Description (GHD (2019))	Propose to address in updated model
5	Thickness of the UEVF and LEVF at the coastal end of the Jan Juc Syncline. Thickness maps suggest the UEVF and LEVF thin out on the eastern end of the Jan Juc Syncline. There are no bore data to the south of Torquay to establish if the syncline containing thick EVF sediments continues across the coast and offshore. An additional deep monitoring bore on the coast near Jan Juc is required to confirm the thickness and extent of the EVF sediments in the coastal region. This would also provide additional information on groundwater flow in this area;	No additional drilling has occurred in this region. However, as per [1], spatial parameter variability and uncertainty analysis will compensate for such unknowns.
6	Hydraulic conductivity of the MEVF aquitard. The hydraulic conductivity of this unit has not been tested and the values used are based on a suitable calibration of the numerical model, and literature estimates. Geological data and the model calibration suggest that the hydraulic conductivity may be variable between the Anglesea Syncline and Jan Juc Syncline;	As per [1], spatial parameter variability and uncertainty analysis will compensate for such unknowns.
7	Hydraulic properties of other hydrogeological units. Whilst a significant body of pumping stress response data has been collected for the LEVF, UEVF and other aquifers, this testing was relatively short-term, and the development of aquifer boundary effects have been noted in the late-time groundwater level responses. This was made particularly clear during the model recalibration of GHD (2013b). However, long-term behaviour of this boundary effect remains uncertain due to the limited temporal extent of the borefield-stressed data.	The updated modelling includes a 6-month pumping trial. Furthermore, there was further use of the Barwon Water (LEVF) borefield in late 2019 for approximately 6 months. There is also several years of post-Alcoa mining UEVF recovery. Hence there will ultimately be more stress data available than was previously the case. However, it must be noted that there has not been a longer period of LEVF pumping than was available for the history-matching of GHD (2013). Stress-response data will be included in the model history matching process as drawdowns from starting conditions and relatively high weight will be placed on these observations. See Section 5.2. Finer spatial parameter variability than was employed by GHD (2013) will allow for simulation of potential boundary effects.
8	Offshore discharge mechanism and location of saline groundwater. These features have been assumed based on limited information.	The updated model parameterisation and boundary condition design for the offshore area, in conjunction with the proposed uncertainty analysis approach, aims to address this uncertainty. See Sections 4.5.2 and 5.
9	Pre-Alcoa coalmine groundwater levels. These are generally lacking. This means that the impact of the coal mine on the aquifers cannot be confidently assessed;	This issue remains a limitation and cannot be resolved. However, its potential impact on model forecast uncertainty will be addressed through flexible parameterisation of the initial (pre-mining) steady state model stress period. This will be implemented by including uncertainty in steady state recharge rates, as distinct from recharge rates to the subsequent steady state stress periods. See sections 4.4 and 4.5.5.
10	Alcoa mine development history. Mining history is not well known (i.e., pit geometries and elevations). Model calibration suggests that this imposes limitations on the quality of model calibration, particularly to water levels in the UEVF. This may have implications for model forecasts;	Effort has been put in to accurately defining Alcoa's mine pit development history in the updated model. See EHS (2022a) and Section 4.5.10.

Issue	Description (GHD (2019))	Propose to address in updated model
11	Alcoa Pit Lake recovery. As noted by GHD (2019), there was an apparent model overestimation of groundwater inflows in the November 2017-May 2018 period. This issue may be related to model error, or to unknown and un-modelled pit water use activities; it was recommended that the model be re-validated and re-calibrated within the next 2 years, once more pit water level recovery data become available from Alcoa.	This will be addressed through the updated modelling of this report. Significantly more pit water body development data are now available than was the case for GHD (2019). See Sections 4.5.9 and 5.2.
12	Forecast impacts on Anglesea borefield Bulk Entitlement trigger levels: As noted in the introduction to Section 6, whilst the Barwon Water borefield was simulated at 5.7 GL/year constant rate in all climate and pit fill scenarios, it is important to note that Barwon Water's relatively recent sustainable borefield yield work (GHD & Groundwater Logic, 2015) showed that in certain drier climate change cases, borefield yield would probably need to be reduced by varying amounts to avoid exceeding trigger bore drawdown limits. This assumption affects the modelled sustainable UEVF yield assessed in this project, particularly in the natural pit fill cases, in which there is less water in the system; the assessment of this report for these natural fill cases are probably conservative, because Barwon Water will likely be pumping at lower rates than those modelled here.	Not relevant to this report.
13	Anglesea Swamp impacts. A relatively poor calibration to flows in Anglesea Swamp was achieved. Reasons are provided by GHD (2013b). This introduces greater uncertainty to forecast impacts on Anglesea Swamp.	Significantly more stream flow data are available now than was the case for GHD (2013). This should enable resolution of this issue. Flow data will be included in model history matching as described in section 5.2.
14	Groundwater levels. Whilst an extensive monitoring network and program is in place, the available period of record for most bores is relatively short, compared with forecast time periods. The SOBN monitoring of the LEVF (and UEVF) aquifer only began recording water levels in the 1990s, and several bores are now of questionable integrity. No groundwater level information for the LEVF is available prior to this period. These issues pose potential implications for the reliability of the model calibration and forecasts.	A paucity of pre-1990 groundwater level data remain a limitation. However, significantly more groundwater level data are available now than was the case for GHD (2013). These data cover periods of significant hydrologic stress in the UEVF, particularly with the cessation of Alcoa groundwater pumping and pit water body development. There are also more stress-response data available for the LEVF, and even more are available from this year's 6-month pumping test. Not only are there longer periods of groundwater level monitoring than was previously available, but there is also more coverage of more aquifers, particularly the ASA. These changes should enable resolution of much of this issue. Groundwater level data will be included in model history-matching as described in section 5.2. Uncertainty analysis will enable quantification of the implications of data shortcomings on key model forecasts.

2.3 Assumptions at the model planning stage

Underpinning assumptions at the model planning stage include the following:

- Relative changes in groundwater and surface water systems arising from Barwon Water and Alcoa's groundwater abstraction and pit water body development activities are the primary focus of the modelling. Model design is specifically targeted at these objectives, and nothing more.
- Simulation of detailed historical Alcoa coal mining activities such as diversion of overland flow around the pit and the water balance of the historical pit sump is not a model objective. Instead, the focus is on groundwater-related impacts of historical mining activities, which are dominated by Alcoa's groundwater abstraction, maintaining a largely water-free working pit via sump pumping, and open cut mine pit development in different areas over time and their effect on groundwater discharge via shallow groundwater evapotranspiration from a lowered groundwater surface.
- The focus of impact assessment relates to groundwater and surface water flux quantities. Water quality is not explicitly modelled or assessed, although broad inferences may be made regarding potential water quality changes due to Barwon Water and Alcoa's activities using water flux information from the model.
- The complex structure and stratigraphy of the groundwater system is necessarily simplified and idealised in the numerical model, because our geological understanding is based on bore hole data collected at a scale coarser than that of geological variability. Therefore, much about its hydraulic properties and behaviour can only be inferred from the available groundwater and surface data, their limitations, and the limitations of the applied modelling methods. As a result, potentially large uncertainties in some hydrologic behaviours are likely to be encountered. This is not to devalue the utility of modelling; to the contrary, recognition of and accounting for these uncertainties ensures that their potential or actual existence is carried through to their potential implications for model end use - i.e., forecasts of potential aquifer behaviour, and how widely that might range based on what we do and do not know. The approach taken to the modelling *must* therefore account for these uncertainties.
- Little is known of groundwater conditions in the offshore area – i.e., where the coastal saline wedge is located. This may have ramifications for the estimation of onshore groundwater system behaviour. The approach taken to the modelling must also account for these uncertainties.

In recognition of the last two limitations identified above, the modelling approach documented in this report seeks to estimate and account for those limitations and their resulting model uncertainties in a highly flexible manner, in keeping with modern modelling approaches. This assessment of uncertainty will be critical when using model outputs to inform risk-based decision making. It is a positive thing that they have been identified at an early stage, so that they can be recognised and accounted for - uncertainties that have not been identified cannot be accounted for, which may pose problems for model-dependent decision-making.

3. Hydrogeological and Hydrology Characterisation

3.1 Catchment Hydrology

3.1.1 Overview

The catchment hydrogeology is described in detail in EHS (2022a) and GHD (2013, 2019), and therefore a summary has been provided in this document to support the conceptual hydrogeological model (CHM) and numerical model development. EHS (2022a) report also includes a summary of the key hydrogeological findings from Alcoa's recent pumping test trial and should be reviewed in conjunction with this summary.

The key surface water features in the vicinity of the mine pit and Barwon Water's borefield are shown in Figure 3-1 and consist of:

- **Anglesea River, Salt Creek Catchments, and associated Swamplands:**

Anglesea River and Salt Creek are generally ephemeral features that also drain the eastern flanks of the Otway Ranges, and much of the outcropping Eastern View Formation (EVF). Major swamplands are present in the lower reaches of both the catchments.

The swamplands at the lower reaches of each catchment are supported by a water table aquifer formed in the permeable alluvial sediments deposited along the creek valley. The water table rises and falls over the year as rainfall recharge and evapotranspiration occurs. Surface flows into the swampland are attenuated by storage in the alluvial water table aquifer (referred to as the Alluvial Swamp aquifer), and surface water outflow only occurs from the swamps when the aquifer system is at full capacity, generally following significant rainfall events. This is discussed further in Section 3.10 (Groundwater Dependent Ecosystems). It is also noted that a section of Breakfast Creek, a tributary to Salt Creek, is a near-perennial surface water feature which supports a pygmy perch population. This is also discussed further in Section 3.10.

Surface water from both rivers run into the Anglesea Estuary, downstream of Coal Mine Road. The Anglesea River estuary is classified as a wave-dominated intermittently open/closed estuary (GHD, 2021).

- **Spring Creek and Thompson Creek:**

These creeks are located to the east and north of the Anglesea River and Salt Creek, respectively. They largely drain the geological formations which overlie the EVF (i.e. the Demons Bluff Formation).

- **Painkalac Creek:**

This is a perennial creek that drains the Otway Ranges. It is known to have a relatively consistent annual flow, suggesting groundwater baseflow derived from the Otway Group. Distillery Creek, a tributary of Painkalac Creek that drains both the UEVF and LEVF, joins Painkalac Creek immediately north of Aireys Inlet.

Barwon Water's surface water monitoring network has focused on the Anglesea River and Salt Creek Catchments based on the assessment of potential impact risk associated with long term groundwater extraction (GHD, 2013 & 2008).

3.1.2 Flow Duration and Catchment Statistics

Barwon Water has installed seven flow gauging sites and additional pool monitoring sites in the two main catchments (refer Figure 3-1) and currently undertake flow, level, and water quality sampling in adherence with the Monitoring and Assessment Program (MAP) required under their BE.

A summary of the surface water flow statistics from these sites (2009-2018) is presented in Table 3-1 (GHD, 2021), including for the historical flow from site SV2 which was in operation from 1967 to 1982.

Table 3-1 Flow summary statistics over historical record to December 2019

Sub-catchment	Gauge ID	Catchment area (km^2)	Average daily flow (ML/day)	Average yearly flow (ML/year)	Median zero flow days per year
Salt Creek	SV3	4.7	0.3	83	8
	SV1	3.2	1.2	343	98.0
	SV4	24.7	1.2	362	116
	SV2	48.2	1.2	343	250
	SV2 (Historical)[3]		11.5	3,175	16.5
Anglesea River[4]	AV1	16.6	0.4	121	242
	AV2	65.2	1.7	553	183

In the Salt Creek catchment, the surface water flow data shows that the catchment is ephemeral and that generally the daily and annual flow volumes increase further downstream. The exception being between flow gauge SV4 and SV2, located at the upstream end and downstream end respectively of the Swamplands, which recorded similar rates. The number of zero flow days increases down catchment, being due to lower rainfall and the attenuation of the flows in the swamplands and subsequent evapotranspiration processes. At the lower end of Salt Creek, gauge SV2 records no flow approximately 68% of the time. Site SV3 in the Breakfast Creek tributary is the only site which records near perennial flows (across both catchments).

The Anglesea River catchment flow data shows this catchment is also ephemeral, with flow volumes increasing downstream. Flow occurs more regularly, and on average at a higher annual volume from the lower end of the Anglesea Swamplands/catchment than the Salt Creek Swamplands/catchment for the 2010 to 2018 period. However, it is noted that during several peak flow periods, Salt Creek Catchment produces significantly higher peak flows; however, on a yearly average basis higher flow volumes normally occur from the Anglesea Catchment (i.e., 7 out of 9 years the higher volumes came from the Anglesea Catchment). At the lower end of Anglesea River Creek, gauge AV2 records no flow approximately 50% of the time.

3.1.3 Surface water acidity

Acidic surface water flows have been recorded from the Anglesea River catchment. At the lower end of the Anglesea catchment gauge AV2 usually record a pH of <3, while at the lower end of the Salt Creek catchment the pH is slightly higher ranging between 3.5 and 4 (EHS, 2022a). Longer term pH data at or near location at AV2 also shows pH generally ranging between 3 and 4 since 1969 (EHS, 2022a). The source of the acidity is discussed further in Section 3.10.1.2.

[3] Historical flow data from 1967-1982, except yearly flow from 1968-1981; Other flow data from approximately 2009 to December 2019.
[4] AV3 on the mid Anglesea catchment does not have enough data to establish a flow rating curve

3.2 Regional Geological and Hydrogeological Setting

Alcoa and Barwon Water production bores are located within the Jan Juc Groundwater Management Area (GMA) (refer Figure 3-2). The numerical model domain covers most of the GMA, as well as an area offshore (refer Section 4). The geology and hydrogeology of this region has been described in detail previously by GHD (2013 and 2019), and more recently by EHS (2022a) with a focus of the Alcoa area of interest (AOI). Therefore, a summary has been provided in this document to support the CHM and numerical model development.

The Jan Juc GMA incorporates the north-western onshore section of the Torquay Basin, a structurally controlled depression in the Lower Cretaceous-aged Otway Group bedrock. In this section of the basin, it has been predominately infilled with Tertiary-aged non-marine sediments.

Within this portion of the Torquay Basin there is two distinct synclines; the Anglesea (or southern) Syncline and the Jan Juc (or northern) Syncline (refer Figure 3-3) where the sedimentary sequences are up to approximately 500 m and 350 m thick respectively. Separating the two synclines is bedrock high referred to as the Bells Beach Anticline, and along the northern edge of the Jan Juc Syncline and the GMA, is the Torquay Anticline (refer Figure 3-3).

A summary of the main geological units in the region, from youngest to oldest, in the region, is shown in Table 3-2 and interpreted outcrop areas of these main units are shown in Figure 3-3. Detailed geological review within the Alcoa AOI completed by EHS, 2022a provided further breakdown of the UEVF into several key lithological units (refer Table 3-3), which are relevant to the hydrogeological assessment.

Table 3-2 Regional Geological Units

Period	Geological unit	Description	Approximate Thickness and Location
Quaternary	Swamp and Alluvial Sediments	Alluvium consisting of sand, silt, clay and gravel deposited along the local river valleys and swamp deposits such as peat in the main swamplands.	Generally 10 -30m thick. Present along the creek lines (i.e., Painkalac Creek, Salt Creek, Spring Creek, and Anglesea River), and thickest in the Salt Creek Swamp and Anglesea Swamp.
	Colluvium	Sand, silts and clays	Also present along some creek lines.
Tertiary	Moorabool Viaduct Sands	Sand, ferruginous sand, limestone and gravel, and was deposited in a marine environment	Isolated pod to the north of Torquay Township and north of the Bambra Fault
	Torquay Group (including Jan Juc and Puebla Formation):	limestone, marl, calcareous and clayey silt, deposited in a marine environment	This unit is mainly present to the northeast of the Torquay Basin and overlies the Demons Bluff Formation.
	Demons Bluff Formation (DBF), including Anglesea Formation & Salt Creek Formation	Marine deposit of fine-grained micaceous and carbonaceous silts and silty clays. The basal member of the formation is a sandstone unit referred to as the Boonah Formation, which overlies the coal seams of the underlying EVF	Along the coastal stretch between Aireys Inlet and Anglesea and stretches inland on the eastern side of the Anglesea River.
	Boonah Formation	The Formation consists of 1-3 m thick- coarse-grained sand channel units with interbedded minor clay, shale and carbonaceous siltstone.	In the Anglesea coal mine, the Boonah Sands Formation is up to 32 m thick with the permeable sections extending laterally up to 50 m (e.g., representative of disconnected “shoe-string sands”)
	Eastern View Formation (EVF)	Deposited in a non-marine lacustrine or deltaic environment and sub-divided into three distinct units (below)	

Period	Geological unit	Description	Approximate Thickness and Location
	Upper Eastern View Formation (UEVF)	Clay, silty clay, silt and fine to medium grained sand sequences with minor fine gravel lenses. Brown coal seams are common in the top of the sequence.	Unit up to 230m thick in Anglesea Syncline. Coals (i.e. A Group coals) from this unit were formerly mined by Alcoa (generally <50m thick).
	Middle Eastern View Formation (MEVF)	Shale and mudstone., minor sand and gravel lenses present	In the order of 50-60m deep in the Anglesea Syncline and 25-50m thick in the Jan Juc syncline
	Lower Eastern View Formation (LEVF)	Micaceous silts, carbonaceous clays, silty clays, thin brown coal and fine to coarse grained sands and gravels.	The average thickness of the unit is almost 200 m along the Anglesea Syncline and 100 m along the Jan Juc Syncline. The unit is thought to be absent over parts of the Bells Beach Anticline[5].
Lower Cretaceous	Otway Group	Inter-bedded sandstones and laminated grey siltstone and mudstone	The bedrock outcrops on the western side of the GMA, and along the Breakfast Creek Tributary gully.

Table 3-3 Upper Eastern View Formation (UEVF): Geological Sub-units

Period	Geological unit	Sub-unit	Description	Approximate Thickness and Location
Tertiary	*Upper Eastern View Formation (UEVF)*	A Group Coals	The main brown coal mined by Alcoa, and in the upper portion of the UEVF	Up to 36m around the coal mine. The coal is interpreted to extend north of the coal mine (around 1 km north of Salt Creek) and south beyond the coast
		Basal Clay	Grey to pale brown clay layer	Located immediately below the main coal seam. The thickness of this clay varies from 1 to 4m
		UEVF upper sands	Shoestring sands	Primarily found underneath the basal clay & main coal seam in the vicinity of the former mine, and potentially extend towards the coast. Varies from 0.5 m to 25 m with a typical thickness being less than 5m
		UEVF Intermediate	Series of peaty coal and clay. Occasional thin (<0.2m) coarse sand and gravel lenses	Beneath the UEVF (upper) sands, between 60-150m thick with individual coal/clay layers between 2 and 30m in thickness
		UEVF lower sand	Coarse sands with minor claystone and coal intervals.	The total thickness is up to 180m. Alcoa extraction bores were screened across these sands

[5] In recognition of the uncertainty in connectivity over the anticline, the LEVF model layer is continued at 1 m (minimum) thickness over the anticline, and the model history matching process will be used to simulate varying degrees and locations of potential connectivity between the two synclines via the LEVF. Initial hydraulic conductivity values over the anticline in the LEVF are low, but are allowed to increase during model history matching if observation data suggests a degree of connection in places.

3.2.1 Interpreted Geological Surfaces

Based on the work completed by GHD, 2013 and EHS, 2022a, geological unit thickness (isopach) and extent maps were constructed for the numerical model and are shown in Section 4.3, for the follow units:

- Swamp and Alluvial Sediments (Figure 4-3),
- Demons Bluff Formation (DBF), including Anglesea Formation & Salt Creek Formation (Figure 4-4)
- Boonah Formation (Figure 4-5, within the Alcoa AOI)
- A Group coals, including the basal clay (Figure 4-5, within the Alcoa AOI)
- UEVF upper sands (Figure 4-5, within the Alcoa AOI)
- UEVF intermediate (Figure 4-5, within the Alcoa AOI, and Figure 4-4 regionally)
- UEVF lower sands (Figure 4-4)
- MEVF (Figure 4-6)
- LEVF (Figure 4-7)
- Otway Group (Figure 4-7)

3.3 Hydrogeology

The hydrogeology of the region has been described in detail in previous reports (i.e., GHD, 2013a, 2019), while the hydrogeology of the Alcoa AOI is detailed in EHS, 2022a.

In summary, there are three main aquifer systems, the regionally extensive UEVF and LEVF aquifers and the Alluvial / Swamp Aquifer (ASA), formerly referred to as the "Perched Watertable (PWT)"[6], which is present along the main creek lines. The hydrostratigraphy of the region is summarised in Table 3-4.

Table 3-4 Regional Hydrostratigraphy

Period	Geological unit	Sub-unit	Aquifer/Aquitard Name	Lithology	Aquifer/ Aquitard Type
Quaternary	Swamp and Alluvial Sediment	-	Alluvial Swamp aquifer (ASA)	Silt, clay and gravel.	Aquifer, unconfined / semi- confined
Tertiary	Moorabool Viaduct Sands	-	Moorabool Viaduct Sands	Sand, ferruginous sand, limestone and gravel	Aquitard/ minor aquifer to the north of Torquay
	Demons Bluff Formation (DBF)	-	Demons Bluff Formation (DBF)	Fine-grained micaceous and carbonaceous silts and silty clays.	Aquitard generally, but can form a perched water table aquifer in places around the mine
	Boonah Formation	-	Boonah Formation (BF) aquifer	Coarse-grained sand with interbedded minor clay, shale and carbonaceous siltstone.	Aquifer, unconfined to confined
Tertiary	UEVF	A Group Coals	A Group Coals	Brown coal	Aquitard
		Basal Clay	Basal Clay	Grey to pale brown clay layer	Aquitard
		UEVF upper sands	UEVF Upper Sand aquifer	Shoestring sands	Aquifer, unconfined to confined
		UEVF Intermediate	UEVF Intermediate	Series of peaty coal and clay. Occasional thin coarse sand and gravel lenses	Aquitard
		UEVF lower sand	UEVF Lower Sands aquifer	Coarse sands with minor claystone and coal intervals.	Aquifer, unconfined to confined
	MEVF	-	MEVF	Shale and mudstone., minor sand and gravel lenses present	Aquitard
	LEVF	-	LEVF aquifer	Micaceous silts, carbonaceous clays, silty clays, thin brown coal and fine to coarse grained sands & gravels.	Aquifer, unconfined to confined
Lower Cretaceous	Otway Group	-	Bedrock	Inter-bedded sandstones and laminated grey siltstone and mudstone	Aquitard / minor fractured rock aquifer

[6] The PWT was renamed to the ASA based on DEECA Technical Review Panel (TRP) comments that "Perched Watertable" was a misleading term given that this aquifer is not perched in all areas.

3.3.1 UEVF and LEVF Aquifers

In the vicinity of Anglesea, the UEVF is around 200 to 250 m in thickness, and the LEVF is around 200 m in thickness (refer Figure 4-4 and Figure 4-7). The UEVF aquifer consists of brown coal, in the upper portion of the UEVF sequence, and interbedded clay, silty clay, silt and fine to medium grained sand sequences with minor fine gravel lenses. As noted in Section 3.2 above, the UEVF has been subdivided into several sub-units with different hydraulic properties in the vicinity of the coal mine, where intensive drilling data made this possible.

The LEVF consists of unconsolidated micaceous silts, carbonaceous clays, silty clays, thin brown coal seams and fine to coarse-grained sands and gravels.

These aquifers systems are separated by the MEVF aquitard, which is generally 40 to 60 m in thickness. The MEVF generally consists of mudstone and siltstone but also has minor sand and gravel lenses as well as thin brown coal layers. The aquifer systems are thickest in two main synclines, the Anglesea Syncline, and the Jan Juc Syncline (refer Figure 3-3). Underlying the main sedimentary aquifer systems is the basement rocks of the Otway Group.

Groundwater recharge to the LEVF and UEVF aquifers occurs via direct rainfall recharge where both aquifer systems outcrop, and the aquifer systems are unconfined. Groundwater migrates towards the coast, where the aquifer systems become confined, and eventually discharges offshore (refer Section 3.12).

Bore yields from the UEVF aquifer (lower sub-unit specifically) have been recorded more than 50 L/sec (GHD, 2008), while yield from the LEVF aquifer are generally in the order of 30 -40 L/sec.

Representative aquifer parameters from the UEVF Lower aquifer are a transmissivity of 110 m^2/day, average hydraulic conductivity of 0.5m /day, while over the sand layers the hydraulic conductivity was in the order of 4.5 m/day. A representative aquifer storativity was in the order of 9.4 $x10^{-4}$ (GHD, 2008). The derived aquifer parameters from the recent pumping test completed on WB16 were largely consistent with these previous parameters, with an average transmissivity of 91 m^2/day, and hydraulic conductivity of 1.2 m/day (based on a 72m aquifer thickness) and an aquifer storativity of 2 x 10^{-4} (EHS, 2022a).

Pumping tests completed in 2008 and 2009 by Barwon Water in the LEVF indicated aquifer transmissivities between 40 and 330 m^2/day and hydraulic conductivity varying from 0.5 to 40 m/day depending on the sequences tested (GHD, 2013a). LEVF aquifer storativity was recorded between 0.002 and 9 x 10^{-5}. Additional information on aquifer properties is included in Section 4.6.

To the east of Anglesea and along the coast, the Demons Bluff Formation (DBF), consisting of silts and silty clays, acts as an aquitard and overlies the UEVF aquifer. Around the mine and power station the DBF is largely unsaturated likely due to the presence of the mine void, however it forms the watertable aquifer in places, where a discontinuous artificial perched groundwater system has formed related to past impacts from the mine infrastructure (i.e., the cooling tower or ash ponds; EHS, 2022a).

3.3.2 Alluvial Swamp Aquifer (ASA)

In the Anglesea River and Salt Creek valleys younger permeable alluvial deposits overlie the regional aquifer systems. The thickness of the alluvial sediments is generally in the order of 10-20 m but thins towards up-catchment areas and the alluvial body margins (refer Figure 4-3). A water table aquifer system, which supports the large swamplands in the Anglesea River and Salt Creek catchments, has formed within the confines of the alluvial deposits and is referred to as the Alluvial Swamp Aquifer (ASA). In previous reports, (i.e. GHD, 2013) this shallow aquifer had been referred to as the Perched Watertable (PWT) aquifer; reasons for the renaming of this unit are discussed in the introduction to this report section.

As noted in Section 3.1.1, this ASA system is primarily recharged by rainfall and runoff, and to a lesser degree by baseflow from underlying aquifer systems (such as UEVF aquifer), where upwards vertical hydraulic gradients exist. When surface water flow occurs in the upper reaches of these catchments, it is often attenuated by the available storage in the ASA system. Subsequently, surface water flow from the lower end of the catchments and into the Anglesea Estuary only occurs following significant or continuous rainfall events where the ASA system becomes filled and there is no further storage capacity. During drier months, the groundwater within the ASA is

lost through evapotranspiration from the swamp vegetation, and groundwater levels subsequently decline. Discharge from the ASA will also potentially occur as leakage to underlying aquifer systems, where there is a downwards vertical hydraulic gradient. This conceptualisation is shown in Figure 3-23.

It is critical for readers to note and keep in mind that the magnitude of the baseflow component into or out of the ASA is dependent on the direction and level of connection with the underlying aquifers, which is dependent on the following factors, all of which can vary spatially, and some of which can vary over time:

- Vertical hydraulic gradients. This relationship can change spatially and temporally depending on climatic conditions, and groundwater abstraction and mining activities in different areas in question (such as Alcoa's and Barwon Water's abstraction). For instance:
    - In the immediate vicinity of the Alcoa mine, the lower sand units of the UEVF aquifers indirectly underlying the ASA and other shallower aquifer systems, have been historically extracted to supply cooling water for the power station and presumably for pit stability, and pressures have been recovering since cessation of Alcoa mine operations).
    - In other places further away from the mine and groundwater pumping, UEVF aquifers have historically exhibited both upward and downward hydraulic gradient into the ASA. In the headwaters of the catchment, such as the Upper Anglesea Pools and Breakfast Creek tributary area, the gradient between the aquifer(s) underlying the ASA and the ASA itself will mainly vary depending on climatic conditions and local geology (and hydraulic properties).
- Thickness and conductivity of intervening aquitards (i.e., coals and clays). These factors will vary across the Salt Creek and Anglesea River catchments, and therefore the ASA will be gaining in some areas and losing in other areas to greater or lesser degrees. The local hydraulic properties of the geology underlying the ASA in different areas will affect the hydraulic response of the groundwater system to groundwater pumping and/or mining (in terms of vertical gradients) differently in different areas.
- Basin architecture also plays a role in spatially variable directions and magnitudes of hydraulic connection between the ASA and underlying aquifers at different times. Figure 3-4 provides a geological cross-section aligned from northwest to southeast through the Jan Juc GMA and along the axis of the Anglesea Syncline. The section indicates the layered sedimentary sequence and the down-dip transition in the UEVF and LEVF from outcropping unconfined conditions, to deeply buried confined conditions. The interpreted outcrop areas of all the geological units in the study area are also shown in Figure 3-3. The geological layers are also shown in the block diagram summarising the conceptual hydrogeological model (Figure 3-21). These factors will affect connection to and from the ASA in different areas.

Readers should therefore recognise that some of the discussion later in this section may appear contradictory; this is not the case however – it is just that the "gaining" and/or "losing" nature of the ASA (and streams) has always varied spatially and temporally (and always will) due to a wide range of influences.

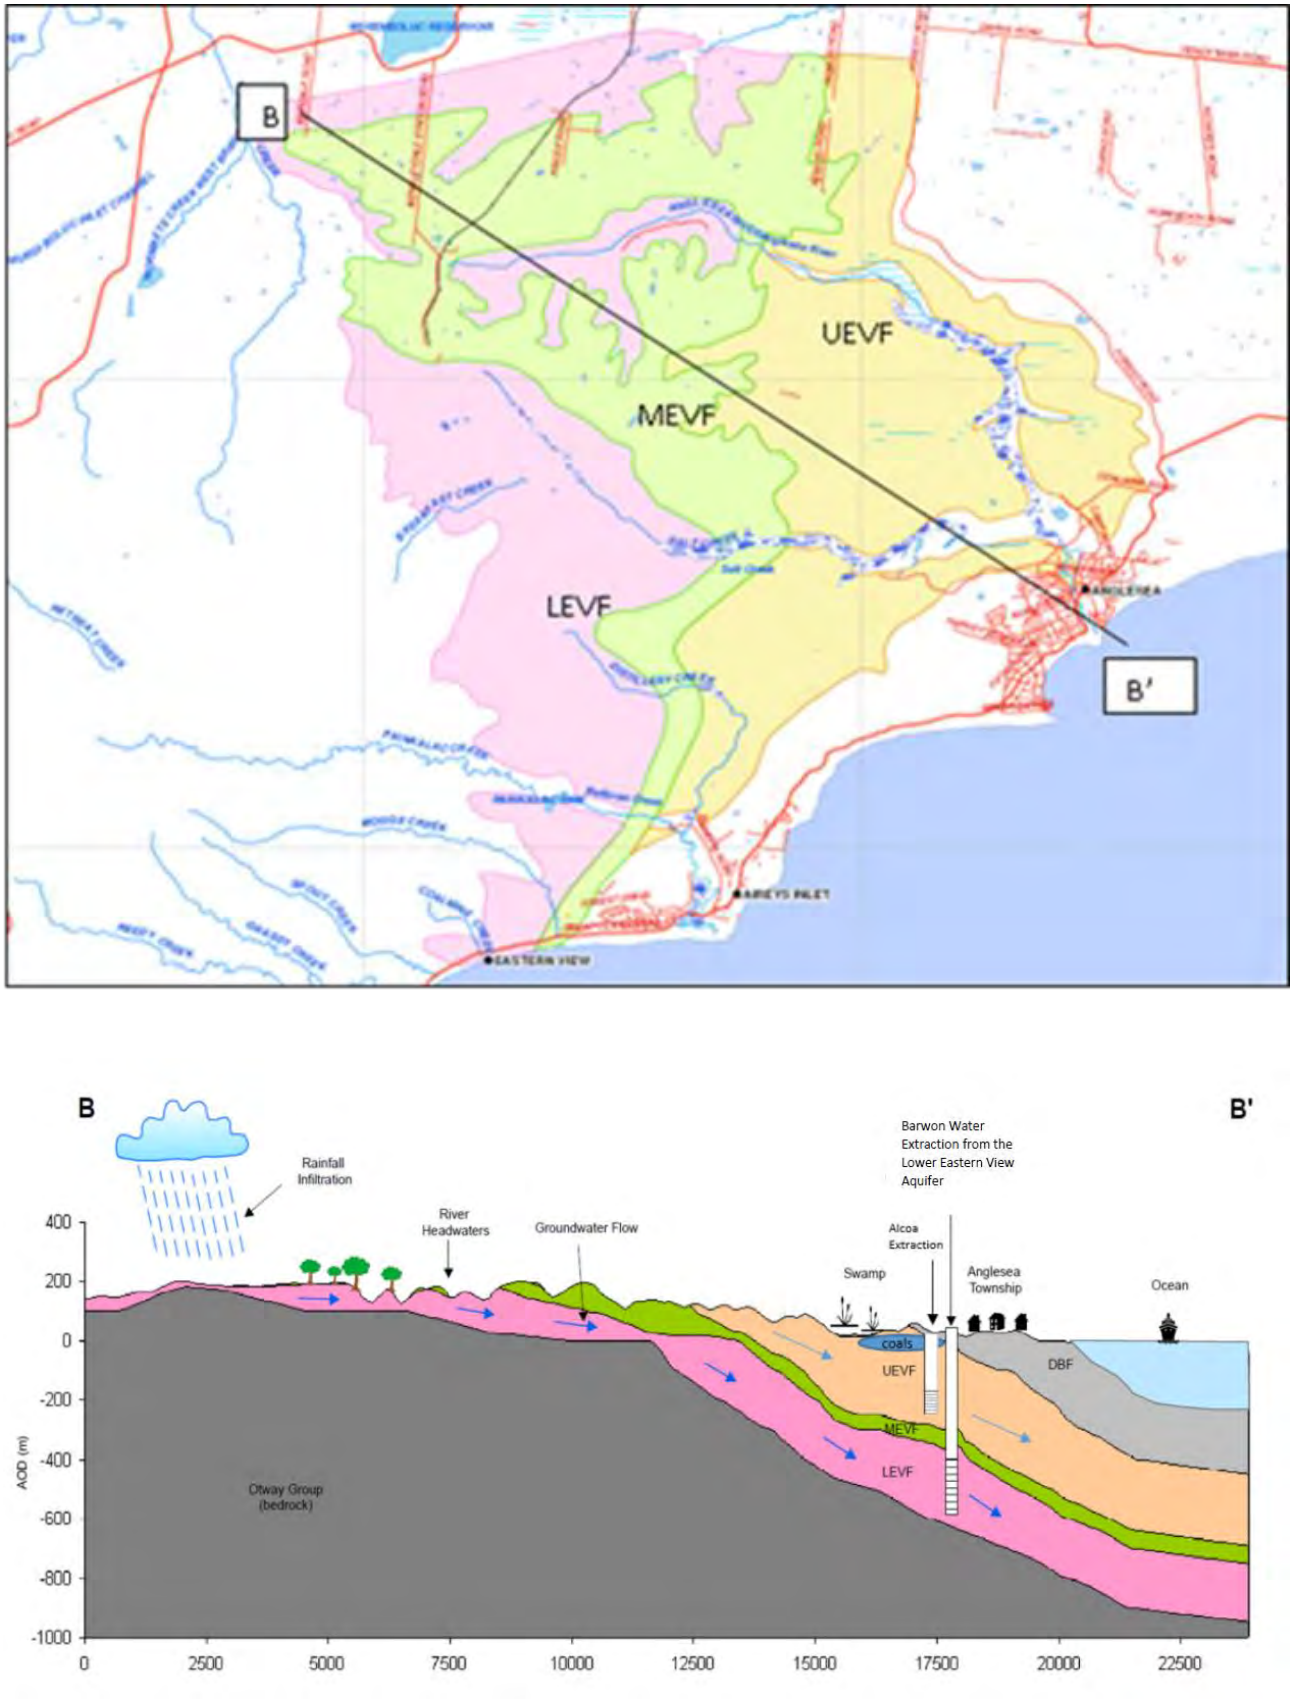

Figure 3-4 *Jan Juc GMA: Cross Section and Interpreted Auifer Outcrop (GHD, 2013)*

3.4 Groundwater Quality

3.4.1 UEVF and LEVF

Groundwater salinity in the UEVF Lower Sands aquifer system has been measured between approximately 800 - 1,200 mg/L Total Dissolved Solids (TDS), whilst the groundwater salinity in the LEVF aquifer system is approximately 500 - 900 mg/L TDS in the Anglesea Syncline and around 600 - 800 mg/L TDS in the Jan Juc Syncline (GHD, 2013).

The groundwater pH from the UEVF Lower Sands aquifer is approximately 5.8 (based on monitoring of 2 observation bores by Barwon Water). Similarly, the average pH from the LEVF aquifer is approximately 5.9 (based on monitoring from 3 observation bores).

Groundwater temperature in the UEVF is generally between 28-33^{0}C in the Anglesea Syncline, while groundwater temperature in the LEVF is marginally hotter and varies from around 34-38^{0}C in the Anglesea Syncline to around 25^{0}C in the shallower Jan Juc Syncline (GHD, 2013).

3.4.2 ASA

Groundwater salinity and pH in the ASA is variable depending on the location in the catchment, seasonal variations, and surface water conditions (i.e., when surface flows occur). ASA groundwater monitoring undertaken by Barwon Water recorded the following salinity and pH trends from April 2015 to Feb 2017 (GHD, 2019):

- In the Anglesea Catchment, groundwater salinity in the ASA generally increased downstream, with ASA aquifer upstream average salinity ~ 1,000 to 1,500 mg/L TDS and the downstream average salinity ~ 2,020 mg/L.
- In the Salt Creek Catchment, the groundwater salinity in the ASA, was similar at the upstream and downstream extents, with upstream average salinity ~ 890 mg/L TDS and downstream average salinity ~ 570 mg/L TDS.
- The greatest salinity variability in the ASA system was recorded in bore WTOB2 at the lower end of the Anglesea Catchment and bore P17 at the upper end of the Salt Creek Swampland (i.e., both bores recorded a standard deviation >200 mg/L TDS).
- Groundwater pH varied between 3.5 and 6.1 in the ASA aquifer system in the Anglesea catchment. The lowest pH was recorded in bore P7B during February 2016.
- Groundwater pH varied between 5.13 and 6.95 in the ASA aquifer system in the Salt Creek Catchment. The lowest pH was recorded in bore P1, at the upstream end of the Salt Creek Swampland in July 2016.

3.4.3 Demons Bluff Formation / Boonah Sands Aquifer

TDS in the Boonah Sands and DBF perched aquifer from the recent groundwater monitoring event in 2020 ranges between 578 mg/L and 6,660 mg/L with an average of 2,519 mg/L (EHS, 2022a).

3.5 Groundwater Monitoring Network

In the Jan Juc GMA there is an extensive groundwater monitoring network, consisting of State Observation Bore Network (SOBN) bores, Alcoa bores and Barwon Water bores (Figure 5-3). The network is summarised below, and a full list of observation bores, and bore location figure, is included in Appendix C. There are several key nested bore sites which are summarised in Table 3-6.

Table 3-5 Groundwater Monitoring Network Summary

Aquifer Monitored	Number of Monitoring Bores	Comment
ASA	9	Barwon Water bores installed for their Monitoring and Assessment Program (MAP)
DBF	21	Alcoa bores on mine site
Boonah Formation	40	Alcoa bores on mine site
Mine Overburden	3	Alcoa bores on mine site
UEVF Upper	7	Alcoa bores on mine site- around the pit
UEVF intermediate	1	Alcoa bores on mine site
UEVF Lower	13	Alcoa, DELWP and Barwon Water bores
LEVF	20	Barwon Water and DELWP bore
Total	137	

Table 3-6 Key Nested Bore Sites

Bores	Aquifer	Location/Justification
Southern Syncline		
116459/115867 / WT0B1	UEVF/ LEVF/ ASA	Nested site at salt creek. SOBN bores may have failed
115868/P15	UEVF/LEVF	West of Barwon Water borefield and the former mine
SB1/SB2	UEVF/LEVF	Vicinity of Barwon Water borefield and the Alcoa extraction bores
P14/P21	UEVF/ LEVF	On the coast. P21 has just been installed (Dec 2021)
P1/P6	LEVF/ASA	Salt Creek, and a nearby a surface water gauge
UEVF MB1 / DBG MB1	UEVF Upper and Boonah sand	Monitoring shallow aquifer systems around the pit lake
UEVF MB2 / DBG MB2	UEVF Upper and Boonah sand	Monitoring shallow aquifer systems around the pit lake
UEVF MB3 / DBG MB3	UEVF Upper and Boonah sand	Monitoring shallow aquifer systems around the pit lake
UEVF MB4 / DBG MB4	UEVF Upper and Mine overburden	Monitoring shallow aquifer systems around the pit lake
UEVF MB5 / DBG MB5	UEVF Upper and Mine overburden	Monitoring shallow aquifer systems around the pit lake
UEVF MB6 / DBG MB6	UEVF Upper and Mine overburden	Monitoring shallow aquifer systems around the pit lake

Bores	Aquifer	Location/Justification
UEVF MB7 / DBG MB7	UEVF Upper and Boonah sand	Monitoring shallow aquifer systems around the pit lake
UEVF MB8 / DBG MB8	UEVF(Intermediate) and Boonah sand	Monitoring shallow aquifer systems around the pit lake
Northern Syncline		
NB2/NB1	UEVF / LEVF	Monitoring in the vicinity of Barwon Water's northern borefield
P8/P19/P12	ASA/UEVF/LEVF	Monitoring head differences in the vicinity of the upper Anglesea River swamplands
P13B/P13	ASA/LEVF	Upper Anglesea River

3.6 Jan Juc GMA: Permissible Consumptive Volume (PCV) and Licenced Groundwater Use

3.6.1 PCV

Both the UEVF and LEVF aquifer systems are managed under the Jan Juc Groundwater Management Area (GMA) (refer Figure 3-3).

The Permissible Consumptive Volume (PCV) for the Jan Juc GMA is currently set by DELWP, 2009 at:

- Zone 1: All Formations: 250 ML/year.
- Zone 2: UEVF: 4,000 ML/year.
- Zone 2: LEVF 35,000 ML total in any 5-year period (i.e. 7,000 ML/year average).
- Zone 2: All formations other than LEVF and UEVF: 0 ML.

3.6.2 Licenced Groundwater Volume and Use

Within the GMA the current licenced groundwater volume is 11,250 ML/year, consisting of the following licences:

- Alcoa: 4,000 ML/year from the UEVF aquifer (historical licence subject to amendment by SRW based on current investigations).
- Barwon Water: 7,000 ML/year from the LEVF aquifer
- Moriac Quarry: 250 ML/year from the LEVF aquifer

Timeseries charts of groundwater usage for Alcoa and Barwon Water bores are presented in Appendix B.

Alcoa ceased extraction from the UEVF aquifer for the mine dewatering and cooling tower supply in March 2016. Following this there was some short-term testing at bore WB16 in mid-2020, and then a 6-month test at WB16 from May 2021 to December 2021 at a rate of approximately 3.5 ML/day.

Barwon water ceased extraction following a 6-month pumping test in early June 2012. Barwon Water then recommenced extraction in late 2019 to July 2020 from several of their southern borefield bores only. A pumping trial from both the northern and southern borefields was then commenced in late January 2022 and ceased in late July 2022. The Barwon Water pumping trial design and objectives were documented in GHD, 2020.

3.7 Groundwater Potentiometric Contours and Flow direction

3.7.1 UEVF Aquifer

The interpreted groundwater elevation contours (or potentiometric surface) in the UEVF aquifer in February 2022 is shown in Figure 3-5. Note that near the Alcoa mine this is based on bores screened in the UEVF Lower Sands aquifer.

The groundwater contours indicate that groundwater flow direction in the UEVF aquifer is generally towards the south and south-east in the Anglesea syncline, from the outcrop recharge area and towards the drawdown cone developed due to Alcoa groundwater extraction from bore WB16, and remnant drawdown from pumping pre-2016.

In the north, there is a component of groundwater flow towards the north-east along the Jan Juc Syncline.

Groundwater contours from the Boonah sands and UEVF upper sands are included in EHS, 2022a, with groundwater flow generally towards the mine void.

3.7.2 LEVF Aquifer

The interpreted groundwater elevation contours (or potentiometric surface) in the LEVF aquifer in February 2022 is shown in Figure 3-6.

The contours indicate that groundwater flow in the LEVF aquifer is towards the south-east in the Anglesea Syncline, and towards the drawdown cone developed around Barwon Water's extraction bores (which have been pumping discontinuously since late January 2022).

The groundwater contours are separated in the north-east due to the absence of the LEVF aquifer system over the Bells Beach anticline. In the Jan Juc Syncline groundwater flow is generally to the east when extraction is not occurring, however currently groundwater flow is largely towards Barwon Water's extraction bores GW7 and GW6, which again have been pumping intermittently since January 2022.

3.8 Vertical Hydraulic Gradients

In general, there is an upwards gradient from the LEVF to the UEVF aquifer system. In the Anglesea Syncline the upwards gradient had historically been enhanced by the drawdown in the UEVF caused by Alcoa's long-term extraction. Although Alcoa has ceased full scale extraction and UEVF levels have recovered significantly, there is still an upwards gradient in the lower end of the syncline (refer Figure 3-7).

Figure 3-8 shows post January 2020 data, when Barwon Water started extraction. This shows the vertical gradient was reversed to downwards for a short period of around 6 months. Subsequently, when Barwon Water ceased extraction the vertical hydraulic gradient returned to an upward gradient, which increased in magnitude once Alcoa started the 2021 pumping test from GW16. Ongoing monitoring in 2022 showed the vertical gradient reversed again to downwards near the end of Barwon Water's pumping trial.

In the Jan Juc Syncline, there is also generally an upwards gradient from the LEVF aquifer to the UEVF aquifer (refer Figure 3-9), with the LEVF aquifer being artesian in the Anglesea River valley (refer Figure 3-10, which includes P18 in the ASA). It is noted that when Barwon Water undertook extraction from the LEVF over the 6-month trial in 2012 the LEVF head was drawn below the UEVF head, reversing the vertical hydraulic gradient.

The head difference and the interaction between the LEVF and the UEVF with the ASA aquifer (and GDEs) is described further in Section 3.10.

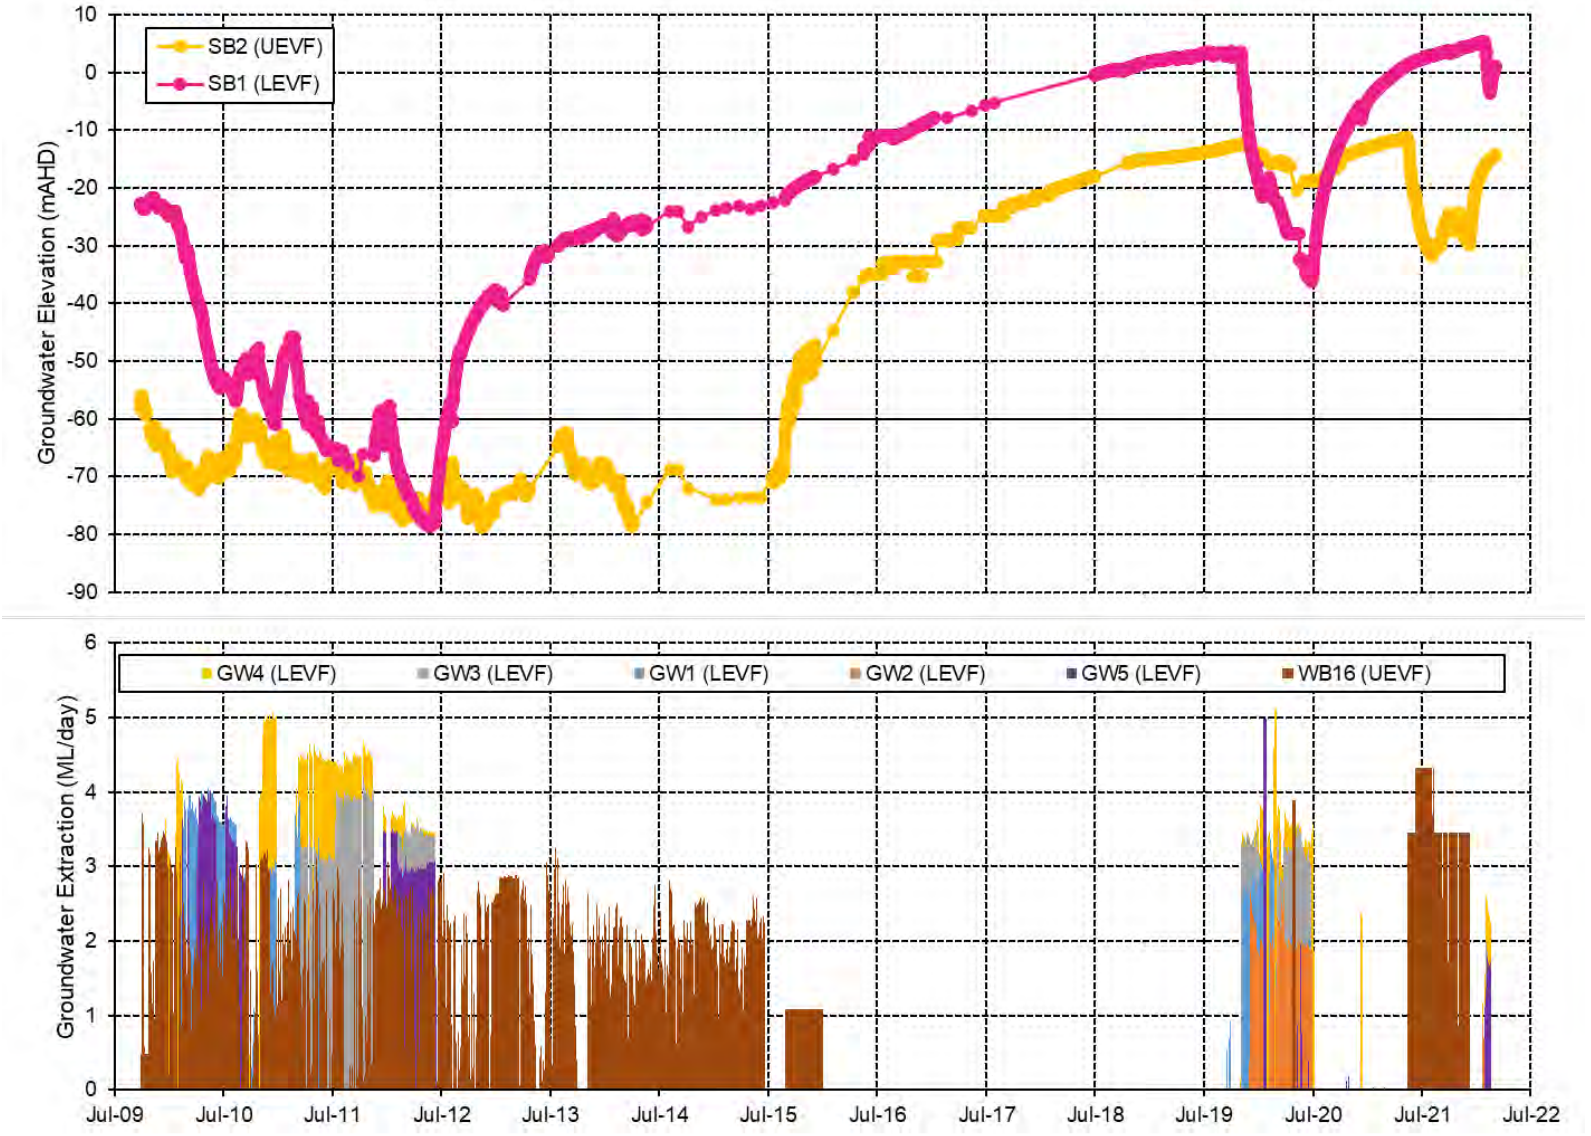

Figure 3-7 ***Southern Syncline: Nested Bores SB1 (LEVF) and SB2 (UEVF) (2010-2022)***

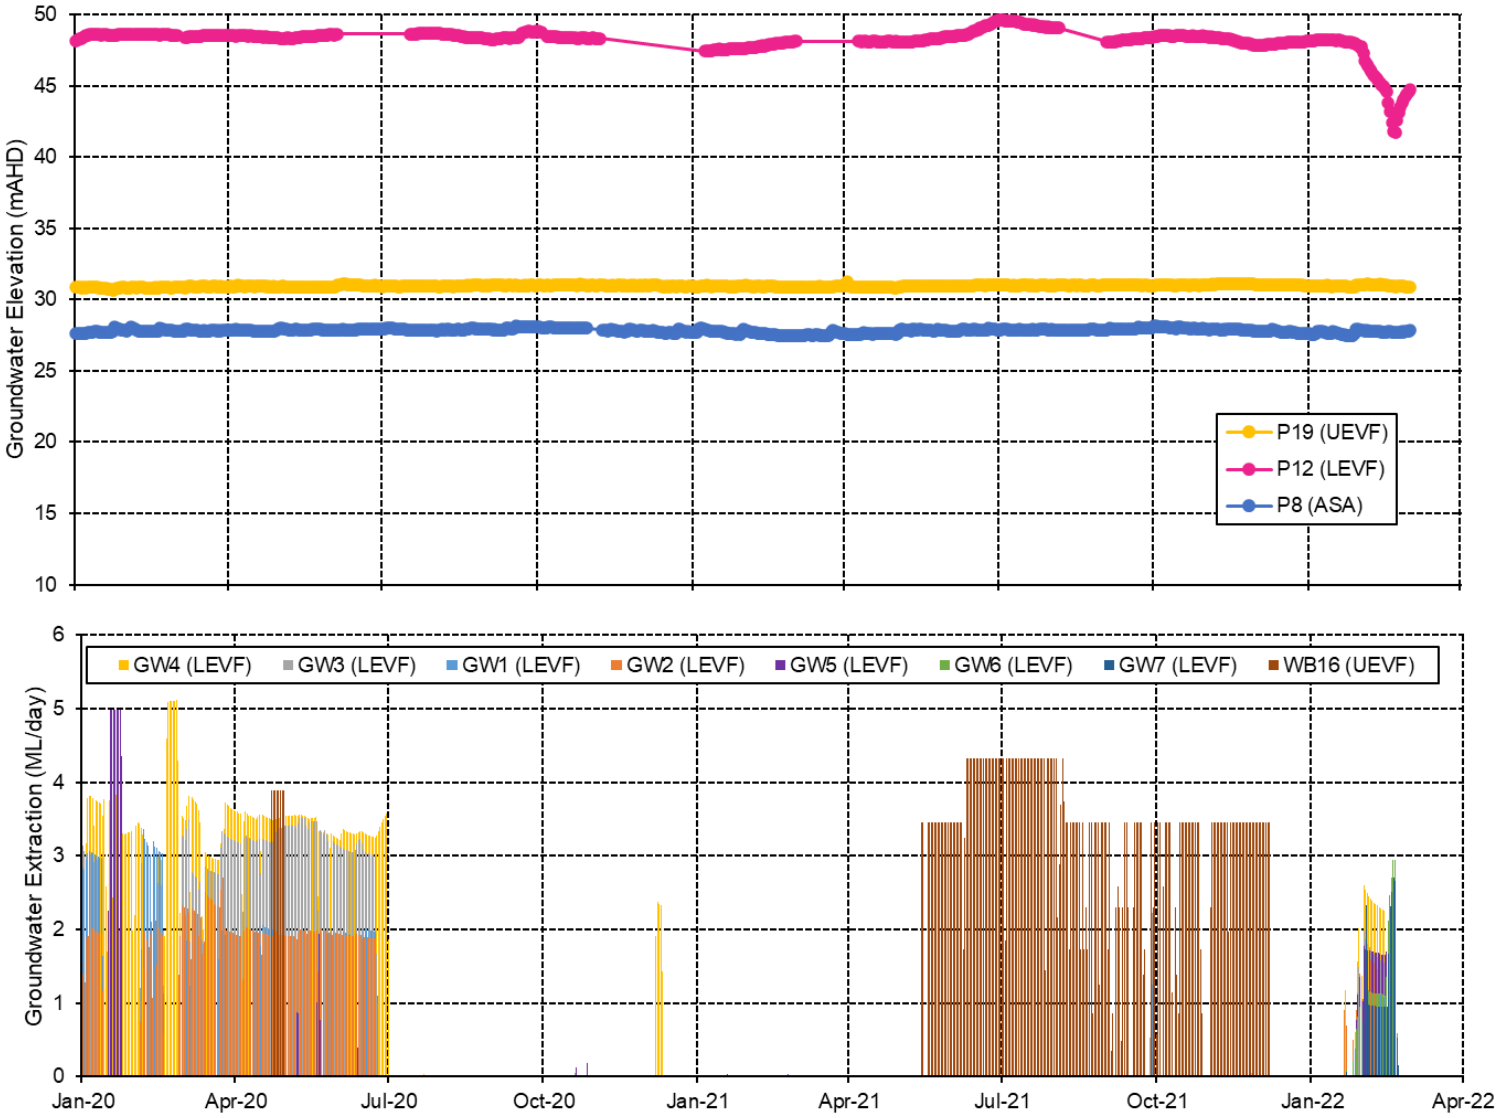

Figure 3-10 Nouthern Syncline: Nested Bores P8 (ASA), P19 (UEVF) and P12 (LEVF)

3.9 Inter-aquifer connection

The degree of interaction between the UEVF and LEVF will be driven by the groundwater gradient and the hydraulic conductivity and thickness of the MEVF aquitard separating the aquifer systems. Similarly, movement between individual aquifer layers (i.e., UEVF Upper sands and UEVF Lower sands) within the same main aquifer system will depend on vertical head gradients, aquitard permeability and thickness.

It is noted that the long- term average calibrated model water balance (1969-2012) for the LEVF aquifer completed in 2013 (GHD, 2013a), indicates that the inter-aquifer flow into the LEVF and out of the LEVF aquifer was broadly equal.

Previous groundwater modelling (GHD, 2013a) indicated that under the scenario of Barwon Water abstraction from the LEVF (i.e., 7,000 ML/year over a 43 year period), additional groundwater is predicted to be drawn into the LEVF from the UEVF aquifer though the MEVF aquitard, and ultimately from the overlying ASA aquifer in certain areas. For context, predicted drawdown cones from the 2013 model, under the median climate scenario, associated with abstraction from the LEVF are shown in Figure 3-11. This figure shows the greatest drawdown in the ASA, associated with Barwon Water extraction of 7,000 ML/year continuously after 5 years, is in the area of the upper Anglesea Swampland, where subsequently trigger levels were established to ensure any drawdown impact was identified and appropriate measures taken to prevent impacts of GDE's (refer Section 3.10.2.1 for further detail).

It is also noted that prior to July 2020, a number of Alcoa UEVF monitoring bores (WB4, WB5, WB12, WB14 and WB15) show a minor but distinct response to Barwon Water extraction from the LEVF aquifer. This response was reviewed and discussed with Alcoa and inter-aquifer connection was concluded to likely be related to a number of Alcoa bores which intersected the MEVF aquitard and potentially the LEVF aquifer (i.e. WB9, WB10). A number of these Alcoa bores have since been decommissioned (WB5, WB9, WB10, WB13, WB17) to further minimise interaction. At the time of writing, no response has been observed in the groundwater levels at the remaining Alcoa observation bores associated with Barwon Water's LEVF extraction, which commenced in January 2022, indicating the decommissioning works have reduced the degree of interaction between these aquifers at this location.

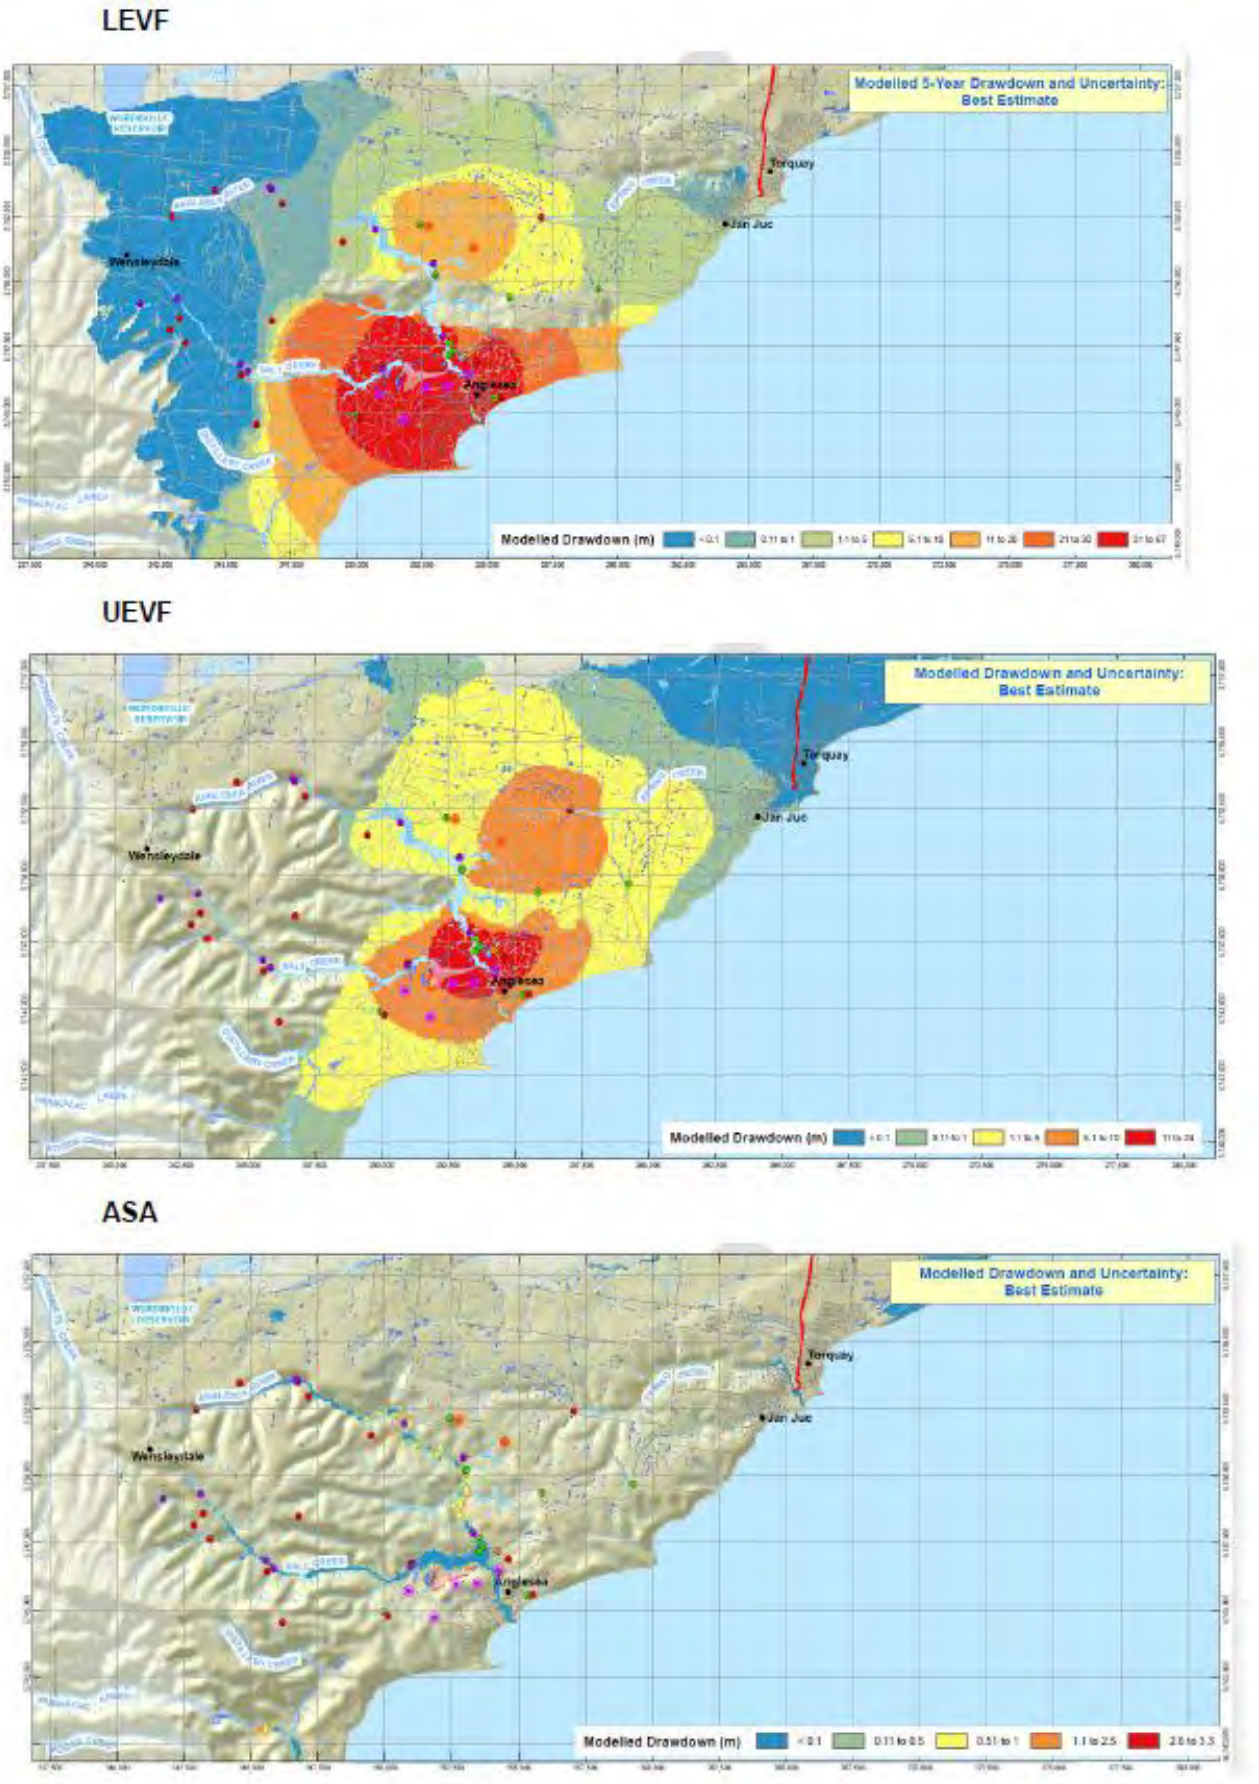

Figure 3-11 Modelled 5 -year drawdown in ASA, UEVF and LEVF associated with Barwon Waters LEVF Extraction (7,000 ML/year)

3.10 Groundwater-Surface Water Interaction and Groundwater Dependent Ecosystems

In general, discharge from some aquifer systems can provide baseflow to surface water features such as swamps, lakes and rivers and support Groundwater Dependent Ecosystems (GDE's) such as terrestrial flora and fauna (for example riverside vegetation and frogs), and aquatic ecosystems (for example, macro-invertebrates).

In the Anglesea region, groundwater and surface water level and flow data was reviewed and incorporated into the BE Review Numerical Model (GHD, 2013a) and groundwater-surface water interaction was modelled (refer Figure 3-12). This generally shows that the lower end of the Salt Creek and Anglesea River catchments are potentially losing in average climate conditions over the 1969-2012 model calibration period, while in the upper reaches the catchments are potentially gaining, however this relationship is a snap shot in time and dependent on interaction of the shallow ASA with underlying aquifers, and will vary spatially and temporally depending on climatic conditions and groundwater extraction in the region (as noted in Section 3.3.2).

In the Salt Creek and Anglesea River catchments, there are three key natural features which are supported by local groundwater discharge to the ASA aquifer, being:

- Anglesea Swampland
- Salt Creek Swampland.
- Breakfast Creek Tributary.

Drawdown in the aquifers supporting these features may impact the GDE heath and therefore need to be monitored and managed. Barwon Water has installed an extensive network of groundwater monitoring bores and surface flow and level gauges to improve the understanding of groundwater-surface water interaction at these GDE's and our current conceptualisation of these features (GHD, 2013a, and EHS, 2022a) is discussed below.

In addition, the mine void is an area that is gaining groundwater due to seepage from the UEVF aquifer and the Boonah and DBF aquifers; this is discussed later in this section.

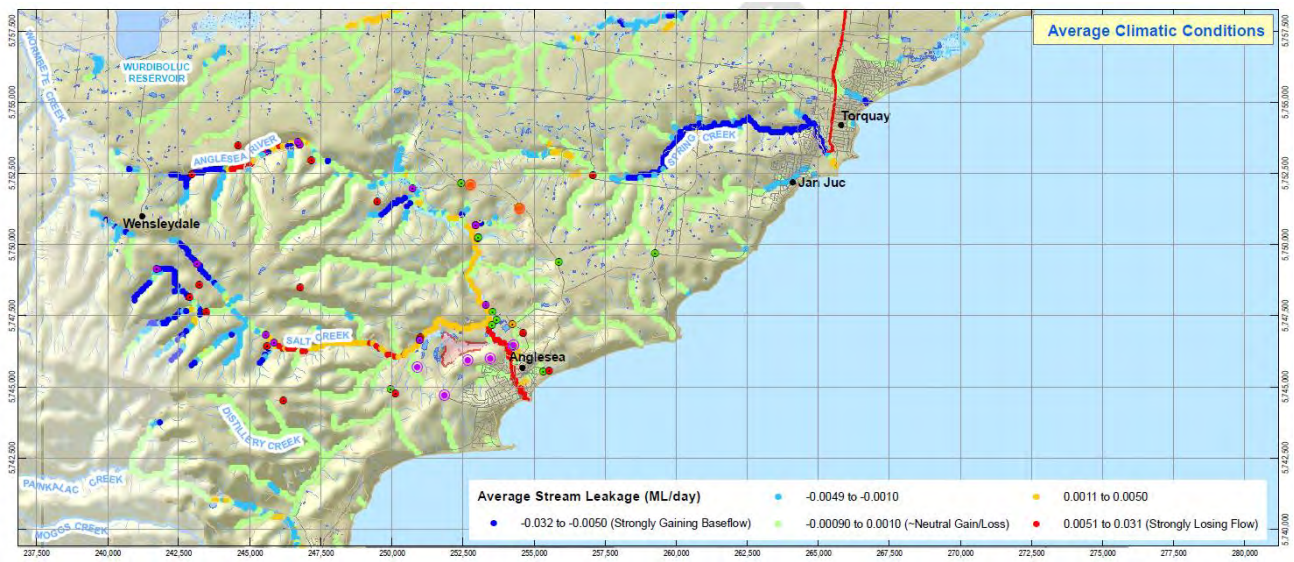

Figure 3-12 Modelled Stream –Aquifer Interaction (GHD, 2013a)

3.10.1 Anglesea and Salt Creek Swamplands

3.10.1.1 General

As noted previously, the swamplands at the lower reaches of each catchment are supported by the shallow water table aquifer formed in the permeable alluvial sediments deposited along the creek valley. The water table aquifer acts like a sponge which is predominately refilled by rainfall and runoff and, to a lesser degree, baseflow from the underlying aquifer system (i.e., the UEVF). The magnitude of the baseflow component (or discharge losses) is dependent on the level of connection with the underlying aquifers, which is dependent on vertical hydraulic gradient and the thickness and conductivity of intervening aquitards (i.e., coals and clays; refer Figure 3-23). The water table rises and falls over the year as recharge and evapotranspiration occurs.

Surface flows into the swampland are attenuated by storage in the ASA, and surface water outflow only occurs from the lower end of the swamplands when the aquifer system is at full capacity. In the Anglesea River Swamp, although flow is ephemeral, there are several wetlands that appear to be near perennial.

The Anglesea River Swamp overlies both the Anglesea Syncline and Jan Juc Syncline geological structures (refer Figure 3-1). In this report the northern section of the swamp overlying the Jan Juc Syncline has been described as the *upper Anglesea River Swampland*, and the southern section overlying the Anglesea Syncline has been described as the l*ower Anglesea River Swampland* (refer Figure 3-1).

The Salt Creek Swamp overlies the Anglesea Syncline. There is a smaller swamp located in the upper reaches of the Salt Creek catchment, above the confluence of Breakfast Creek, and this has been referred to as the Upper Salt Creek Swamp.

As noted in Section 3.1.2 the Anglesea River and Salt Creek are ephemeral and no surface water flows occur on average 50% and 68% of the time at the downstream gauges of the catchments, which also reflects the flow attenuating capacity of the swamps.

3.10.1.2 Acid Generation

As detailed in Section 3.4.2, groundwater salinity in the ASA varies across the catchments being around 2,000 mg/L TDS at the lower end of the Anglesea Swampland and around 600 mg/L TDS at the lower end of the Salt Creek Catchment and the groundwater pH is as low as 3.5 in the Anglesea catchment.

During large first flush events of the swamps (i.e., after a period of no flow, wet periods fill the ASA storages and flow is seen at the lower ends of the swamp), significant volumes of acidic water can be flushed into the estuary which may cause low pH, metals precipitation and, in some cases, fish kills (GHD, 2013a). As noted in Section 3.1.3, the surface water acidity at the lower end of the catchments commonly has a pH <4, since monitoring began in 1969.

The conceptualisation of acid generation in the catchments (GHD, 2013a) is that the source of acidity in the catchments is naturally occurring sulphides (pyrites) present within the main swamps and possibly coal and other pyritic sediments in the upstream catchments. It is conceptualised that as the water table rises and falls over the year, the pyritic sediments and coals are subjected to wetting and drying cycles, which oxidise the sediments and causes acid generation within the swamplands. The acid is released from the swamp when there is a major rainfall event or consistent rainfall, which fills the water table aquifer in the swamp and flushes the stored acid (and dissolved metals and salts) from the downstream end of the swamp and into the Estuary, which may result in fish kill events. The low pH water may also mobilise additional metals from the catchment (i.e., aluminium) which also may contribute to the fish kills (refer Pope, 2010). GHD (2013a) also reviewed historical fish kill events, and concluded that there were two key processes required to result in a fish kill event associated with an acid flush event:

- The duration between flushing events in the Salt Creek Swamp needs to have been long enough to generate significant acid and metals storage in the ASA.
- The first flush of Salt Creek Swamps needs to be of sufficient volume to affect the estuary (i.e., a small flush volume would be diluted within the estuary).

It was concluded that fish kill events may potentially occur when Salt Creek has had no significant outflow (i.e., >1 ML/day) for longer than 15 months, which is then followed by a first flush event of greater than 4-5 ML/day (GHD,2013a).

This acid generation conceptualisation in GHD (2013a) was based on limited data however has subsequently been confirmed by studies completed by Monash University (2020), which completed an investigation of the acid sulphate soils throughout the Salt Creek and Anglesea catchments and found both Salt Creek and Marshy Creek (i.e., Anglesea River) contain substantial volumes of acidity in a form that can be mobilised rapidly. Marshy Creek contains higher concentrations of labile acidity which can be transported readily in surface water and groundwater, whereas Salt Creek contains higher concentrations of retained acidity which can be slowly released over time. Both catchments were assessed as significant acidification, metal mobilisation and monosulfide formation hazards.

Further updated detail on the conceptual model of acid generation is included in EHS (2022a), and this latest data review suggests that significant low pH conditions from the catchments occur when the no flow period approximately exceeds 180 days and the magnitude of first flush flows is >5 ML/day (AV2 gauge).

With respect to assessment of potential acid generation impacts within the swamplands, two key hydrologic responses that have the potential to increase the rate and extent of acid generation and export are thought to exist:

- The lowering (drawdown) of groundwater levels (and frequency) in the swampland that may increase the exposure of PASS sediments, to oxygen, where present.
- Longer cease-to to-flow periods, where there will be a longer period with no export or dilution of any acid stored in the system and potentially more acid could also be generated by dryer conditions and greater groundwater level fluctuations promoting further oxidation of PASS, where present.

The numerical modelling of hydrologic impacts as outlined in Section 2.2.1 is proposed for initial assessment of impacts on acid generation. Based on these results, and considering the risk of significant impacts, then further geochemical assessment may be required, using sperate geochemical models.

It is also noted that another source of water inflow to the Estuary up until 2016 was treated process water from Alcoa. The cessation of this continual process water flow (around 2.9ML/day at pH ~8) has resulted in lower surface water levels in the estuary, a lower pH and changing ecosystem communities. These changes are detailed further in Section 3.11.

3.10.2 Anglesea Swamplands Hydrogeological Conceptualisation: Interaction with Underlying Aquifers

As noted previously, the Anglesea Swampland hydrogeological conceptualisation (GHD, 2013a) has been split into two main areas; the upper Anglesea Swampland overlying the Jan Juc Syncline and the lower Anglesea River Swampland overlying the Anglesea Syncline (refer Figure 3-1). These conceptualisations focus on specific catchment areas where data is available (i.e., nested bore sites). As described in greater detail in Section 3.3.2, the magnitude and direction of interaction between the ASA and underlying aquifers across the catchments will be dependent on:

- The level of connection with the underlying aquifers, which is dependent on vertical hydraulic gradient and the thickness and conductivity of intervening aquitards. These factors will vary across the Salt Creek and Anglesea River catchments, and therefore the ASA will be potentially gaining in some areas and potentially losing in others.
- Climatic conditions, and mining and groundwater abstraction activities (such as Alcoa's and Barwon waters abstraction) in different catchment areas. This will variably affect the nature of interaction between the ASA and underlying aquifers not only in a spatial sense, but also (perhaps primarily) in a temporal sense.

Readers should therefore try to avoid the temptation to compartmentalise the behaviour of the ASA; its behaviour is complex and varies widely across different areas at different times. The next five sub-sections aim to provide a summary overview of the current understanding of the *typical* behaviour of the ASA in five specific areas (Upper and Lower Anglesea River, Lower Salt Creek, Upper salt Creek/ Breakfast Creek Tributary and around the Alcoa mine), from the available observation data.

3.10.2.1 Upper Anglesea River Swamplands

In the Jan Juc Syncline there is a significant upwards vertical hydraulic gradient from the LEVF towards the UEVF and the ASA (refer Figure 3-13, Figure 3-14 and the Figure 3-10 hydrograph). The MEVF aquitard will limit the connectivity between the UEVF and LEVF (its effectiveness reflected in the LEVF artesian head), and similarly clays at the base of the ASA will limit the connectivity between the UEVF and the ASA. However, the upward groundwater gradient suggests that there is potential for some baseflow from the UEVF to the ASA in this region.

As shown in Figure 3-11 previous modelling (under a proposed LEVF abstraction scenario) showed that over a 5-year period of continuous pumping at 7,000 ML/year, drawdown impacts in this area of the ASA aquifer may occur. Drawdown in the ASA aquifer may then potentially impact on the stream flows from the swamp, which may subsequently influence acid generation. Recognising this risk, a trigger level was developed in this area (Bore P19 and P8) as part of Barwon Water's BE. The trigger level is designed to minimise any drawdown in the ASA aquifer system, and therefore prevent potential impacts on the swampland GDE and potential subsequent downstream impacts. The trigger level response will be predicted under different modelled extraction scenarios using the updated model described in this report.

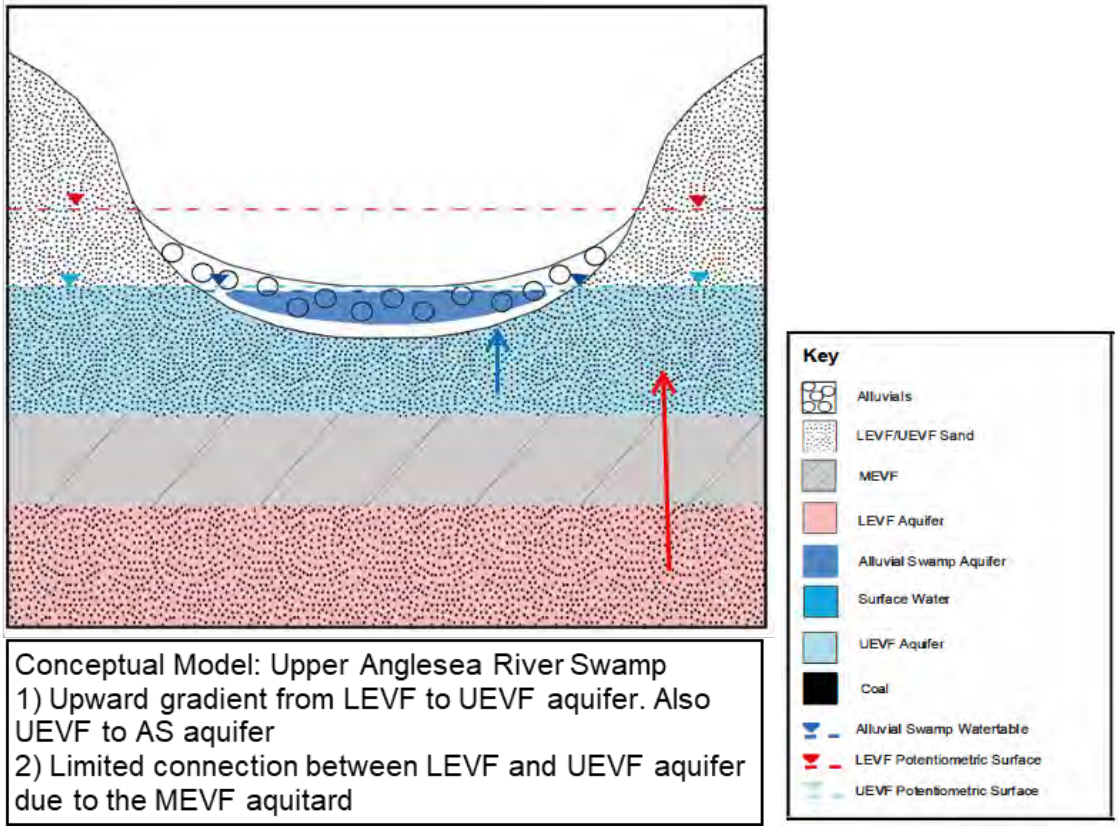

Figure 3-13 Conceptual Model: Upper Anglesea River Swamp (Jan Juc Syncline) (GHD, 2013a)

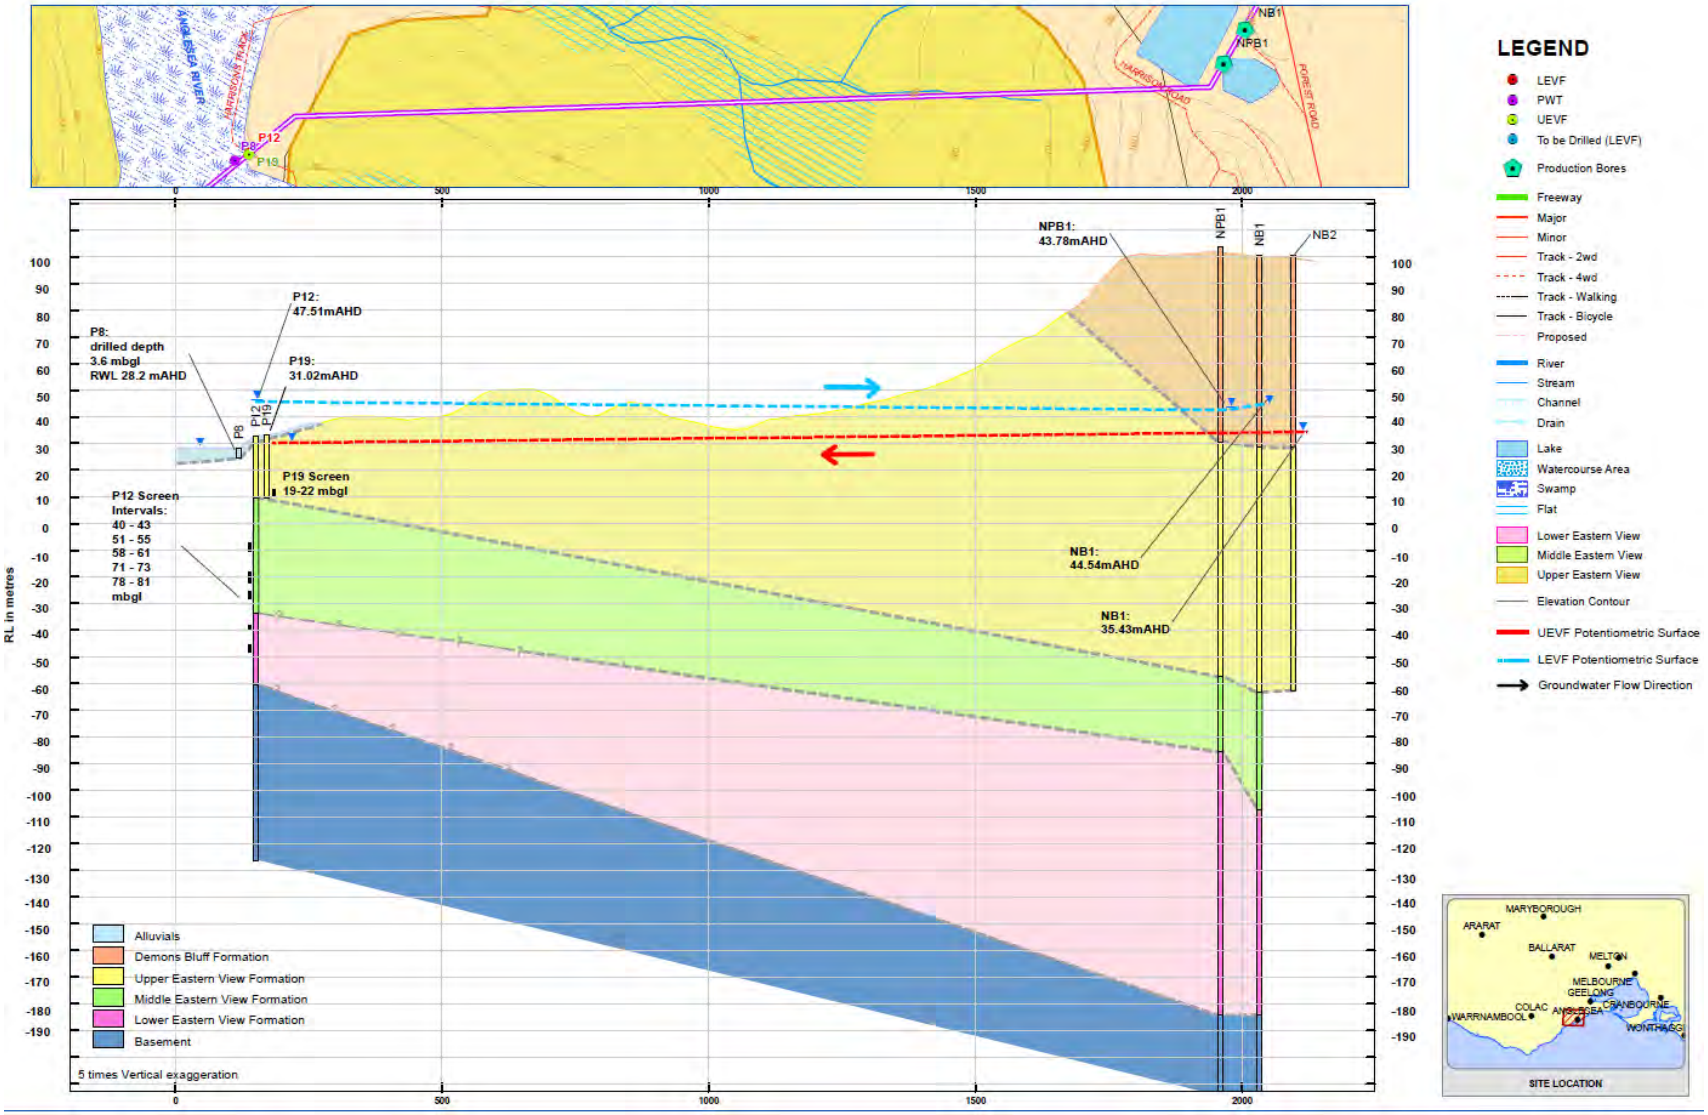

Figure 3-14 Cross Section: Trigger Bores to Barwon Water Northern Pump Bore (GHD, 2013a)

3.10.2.2 Lower Anglesea River Swamplands

The conceptualisation of groundwater interaction with the lower Anglesea River Swamp is shown in Figure 3-15. In this section of the swamp, the LEVF aquifer again commonly has higher heads than the UEVF aquifer and therefore there is an upwards gradient from LEVF to UEVF (although as noted in 3.8, this vertical gradient may reverse depending on whether Alcoa and/or Barwon Water are extracting).

The UEVF lower aquifer, has been drawn down due to the historical pumping from the former Power Station supply bores, and there is also a downward hydraulic gradient from the ASA to the UEVF. The head difference between WTOB2 (ASA) and WB4 (UEVF lower) was approximately 20m as shown in Figure 3-16 prior to the WB16 pumping test and was in the order of 60m while Alcoa was pumping (pre-2016). This downwards gradient is also noted from the ASA to the Boonah Formation aquifer, where saturated around the former power station (EHS, 2022a).

Therefore, as shown by the relative groundwater levels in Figure 3-16 over the last 13 years at least, the ASA aquifer, which supports the swamplands, is generally hydraulically separated from the underlying UEVF lower sands aquifer in the lower reaches adjacent the pit. (i.e. >20m head difference between 2009 and 2022). With the data available (2009-2022), there is no obvious evidence of desaturation of the ASA near the mine pit (in both Anglesea River and Salt Creek catchments), associated with pit dewatering and UEVF extraction, with groundwater levels in the ASA in bores WTOB1 and WTOB2 generally fluctuating between 0.5m and 6m below ground level. In addition, the swamp vegetation and associated ecology has persisted, indicating that the ASA has remained sufficiently saturated to support the vegetation over the long term (i.e. 40 years +) Alcoa operations, and that rainfall/rainfall runoff are the main recharge mechanism for the ASA. This cannot rule out the potential for a subtle influence on the frequency of wetting and drying of the swamplands and the water table depth associated with Alcoa operation. This is also discussed further in Section 4.5.8 and shown in Figure 4-13.

The downward vertical gradient suggests the potential for some diffuse leakage from the ASA towards underlying aquifers over time, however the low permeability coals and clays in the Anglesea Syncline provide an aquitard between the UEVF sands and the ASA in the lower reaches. There is also a degree of hydraulic separation between the ASA and the underlying Boonah Formation aquifer (which is saturated on the eastern side of the mine void) due to the DBF aquitard (refer EHS, 2022a). The interaction between these aquifer systems will vary over time, as potentiometric heads recovery in the UEVF aquifer, and other pumping scenarios occur.

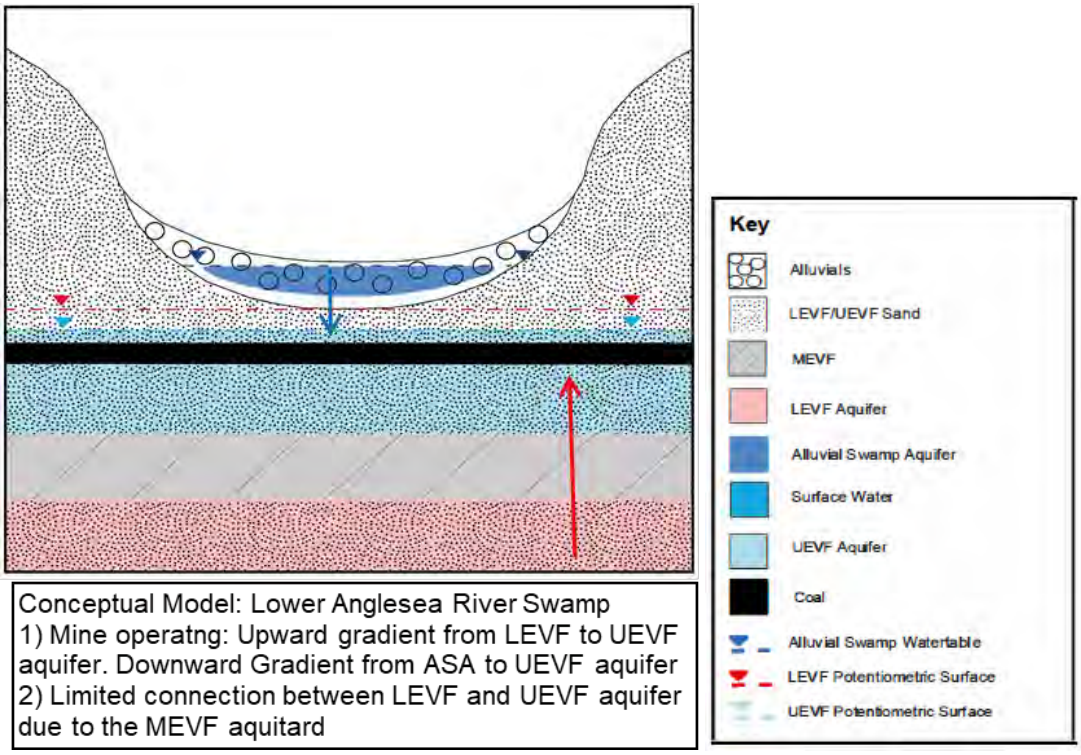

Figure 3-15 Conceptual Model: Lower Anglesea River Swamp (Anglesea Syncline) (GHD, 2013a)

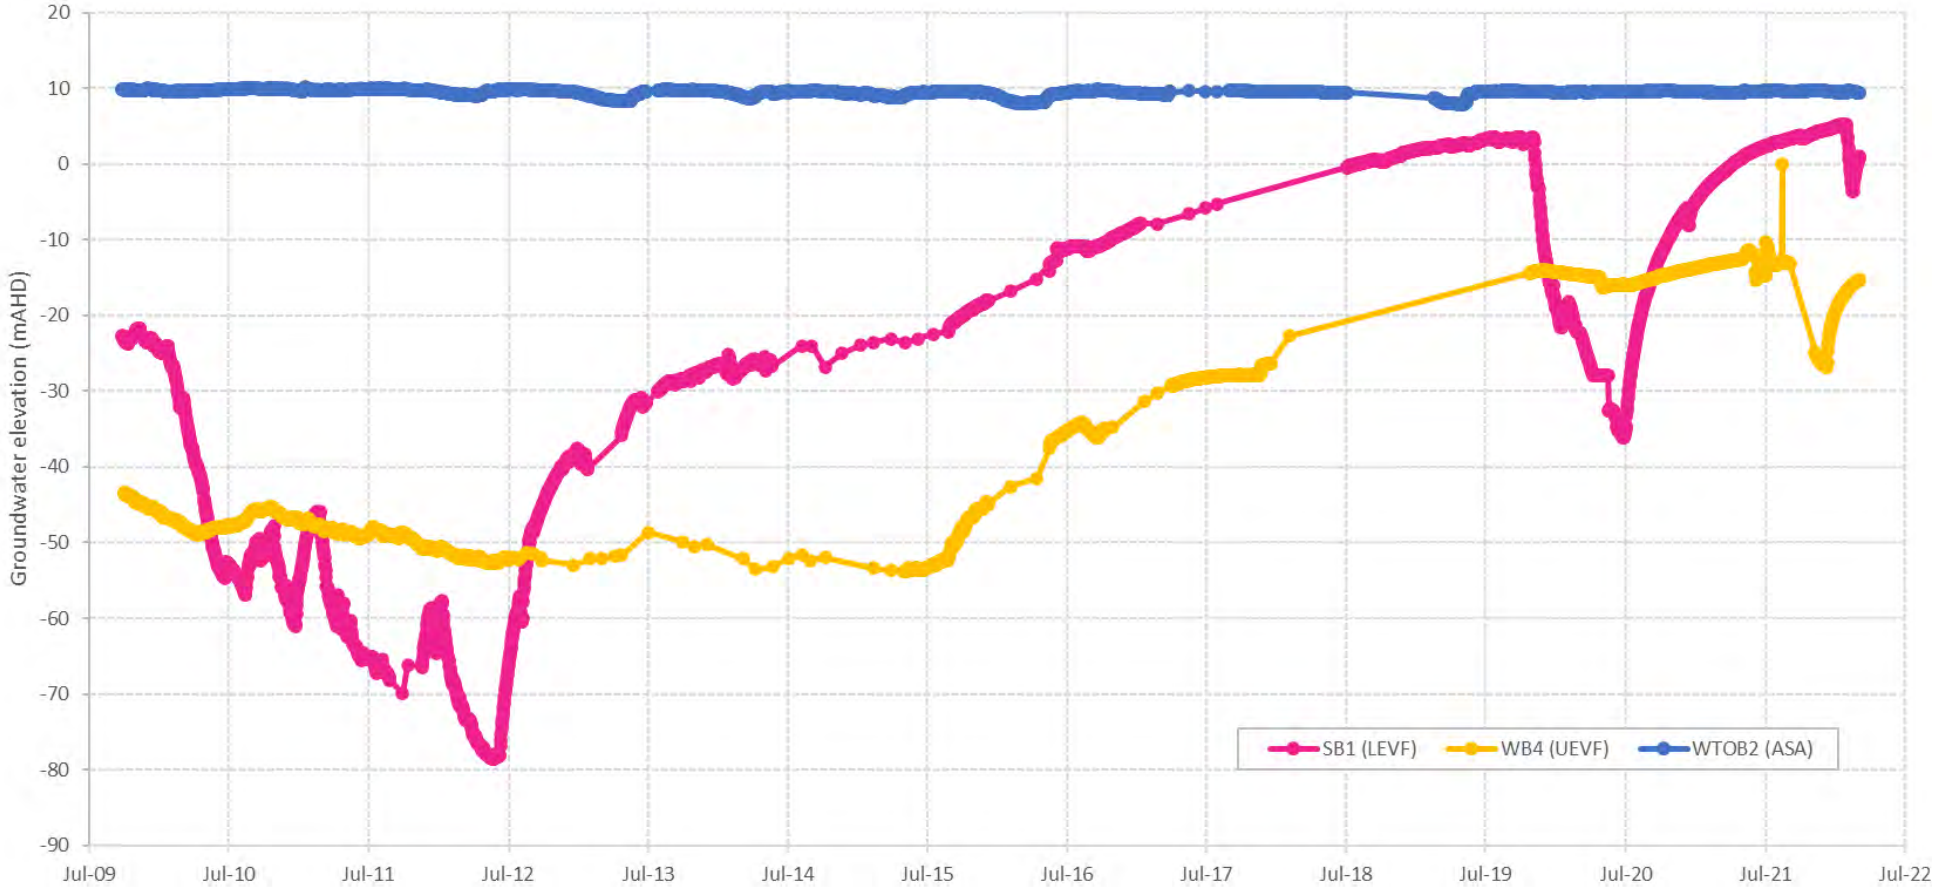

Figure 3-16 Lower Anglesea Swampland: WTOB2 (ASA,)WB4 (UEVF) & SB1 (LEVF) Nested Hydrograph

3.10.3 Salt Creek Swamp (Anglesea Syncline): Interaction with Underlying Aquifers

The Salt Creek Swamp has a similar conceptualisation to the lower Anglesea Swamp (Figure 3-15), with the ASA in the lower section near the mine being generally hydraulically separated from the UEVF lower sands due to long-term drawdown in the UEVF aquifer by the Power Station supply bores and numerous aquitard layers. Like the Anglesea River Swamplands, there is no obvious evidence of desaturation of the ASA in Salt Creek near the mine pit (i.e., bore WTOB1), and the swamp vegetation and associated ecology has persisted throughout the long-term Alcoa operations.

Further upstream where the UEVF drawdown cone is less, there is still an upwards gradient from the UEVF lower sands to the ASA. However, the low permeability coals and clays of the UEVF intermediate unit provide a sequence of aquitards separating the UEVF aquifer from the ASA aquifer in the lower swamp area. The numerical model will be used to provide a further assessment of potential long-term impacts on the ASA, as the drawdown cone and the groundwater gradients stabilise between aquifers over the various long-term pumping scenarios and in combination with on-going recovery in the UEVF aquifer.

3.10.4 Breakfast Creek Tributary

The hydrogeological conceptualisation of interaction in the Breakfast Creek Tributary is shown in Figure 3-17. This tributary overlies the LEVF outcrop area and has near perennial flow. Monitoring site SV3 shows gaining and losing conditions during different periods throughout the year. During the drier summer periods, the tributary at this site generally becomes losing (GHD, 2013a).

The extent of the gaining and losing stretch of the tributary will vary over the year, depending on climatic conditions. Upstream of this monitoring location it can generally be concluded that the tributary continues to receive groundwater baseflow over longer periods during the dry months, which is reflected in the near-perennial flows recorded at the SV3 site. As recorded in March 2010, in occasional dry conditions the tributary ceases to flow at this point as the gaining sections of the creek either retract much further upstream and/or baseflow to the creek ceases altogether.

This tributary supports a pygmy perch population in the Salt Creek catchment, which is an important GDE which requires protection. Modelling of Barwon Water's abstraction from the LEVF (GHD, 2013a) forecast that the drawdown cone would not extend to this location under long-term abstraction and therefore the risk of impacting the GDE was assessed as being moderate.

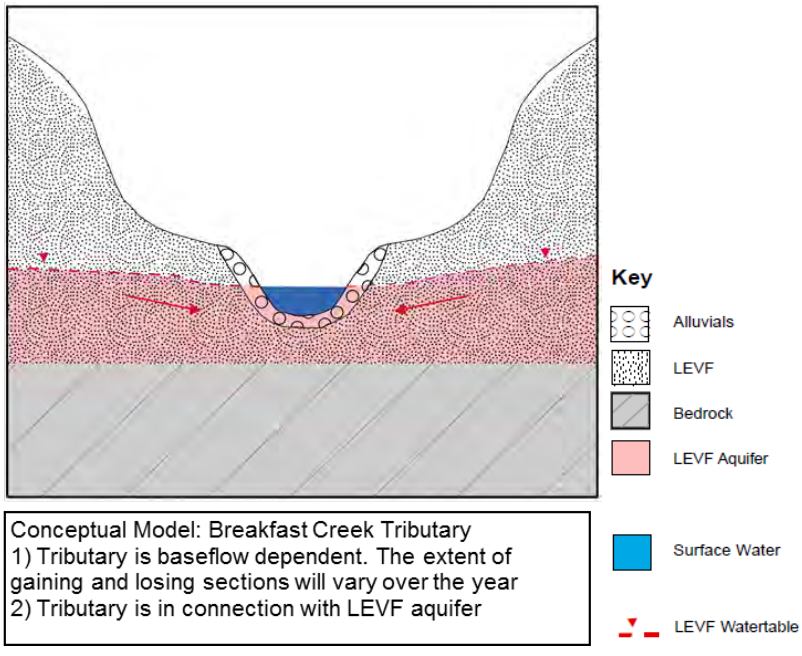

Figure 3-17 Conceptual Model at Breakfast Creek Tributary

3.10.5 Mine Void

In 2020/21, Alcoa installed 16 bores at 8 nested bore sites around the mine void to gather additional information regarding the geology around the pit and groundwater levels in the DBF aquitard, Boonah Sands aquifer and the UEVF Upper sands aquifer. The mine void conceptualisation is shown in Figure 3-19 (EHS, 2022a), including the local lithological units and groundwater levels in the shallow aquifer systems. The information shown in this figure, and the current conceptual understanding of surface water and groundwater interaction around the mine void is summarised below:

- The mine void acts as a groundwater sink to the unconfined Boonah Formation aquifer (EHS, 2022a). Figure 3-18 shows the Boonah Formation aquifer is still saturated on the eastern side of the mine void around the former power station with a groundwater gradient towards the mine. On the western side of the mine the Boonah Formation is unsaturated.
- A discontinous artificial perched water table exists in the DBF sediment underlying the former Power Station (EHS, 2022a).
- The groundwater level in bore UEVF MB07 screened in the UEVF Upper Sands aquifer is slightly lower than the surface water level in the void. This indicates currently there is a downwards vertical gradient towards this bore, although there is expected to be a degree of hydraulic separation from the mine void due to the presence of the basal clay at the base of the pit. The low salinity in this bore ~100 mg/L TDS) suggests the bore is not influenced by the pit surface water level (EHS, 2022a). It is noted that other bores in the UEVF Upper Sands aquifer (i.e., UEVF MB2, MB3 and MB4) have potentiometric heads higher than the surface water in the mine void. Groundwater levels in the UEVF Upper Sands aquifer are likely to be impacted currently by several processes including local recharge, recovery of heads in the UEVF Lower Sands aquifer and the intermediate aquitard following Alcoa ceasing operation, as well as potential leakage to or from the mine void. EHS (2022a) noted that groundwater levels in the UEVF Upper Sands aquifer are generally rising at a similar rate of 0.02 m/month and were not impact by pumping from WB16.
- The potentiometric head in the UEVF intermediate coal (bore UEVF MB8) was approximately 20-25m higher than the UEVF Upper Sands aquifer and the pit surface water level indicating there is an upwards hydraulic gradient from these deeper units towards the shallower aquifer systems and the pit void.
- The development of catchment drains diverts local surface water into the mine void. At times the amount of water these drains can add to the void is significant (EHS, 2022a)
- A water balance for the mine void has been estimated by EHS (2022a). The groundwater baseflow component entering the mine void was estimated at approximately 0.46 to 1.4 ML/day (170-520 ML/year).

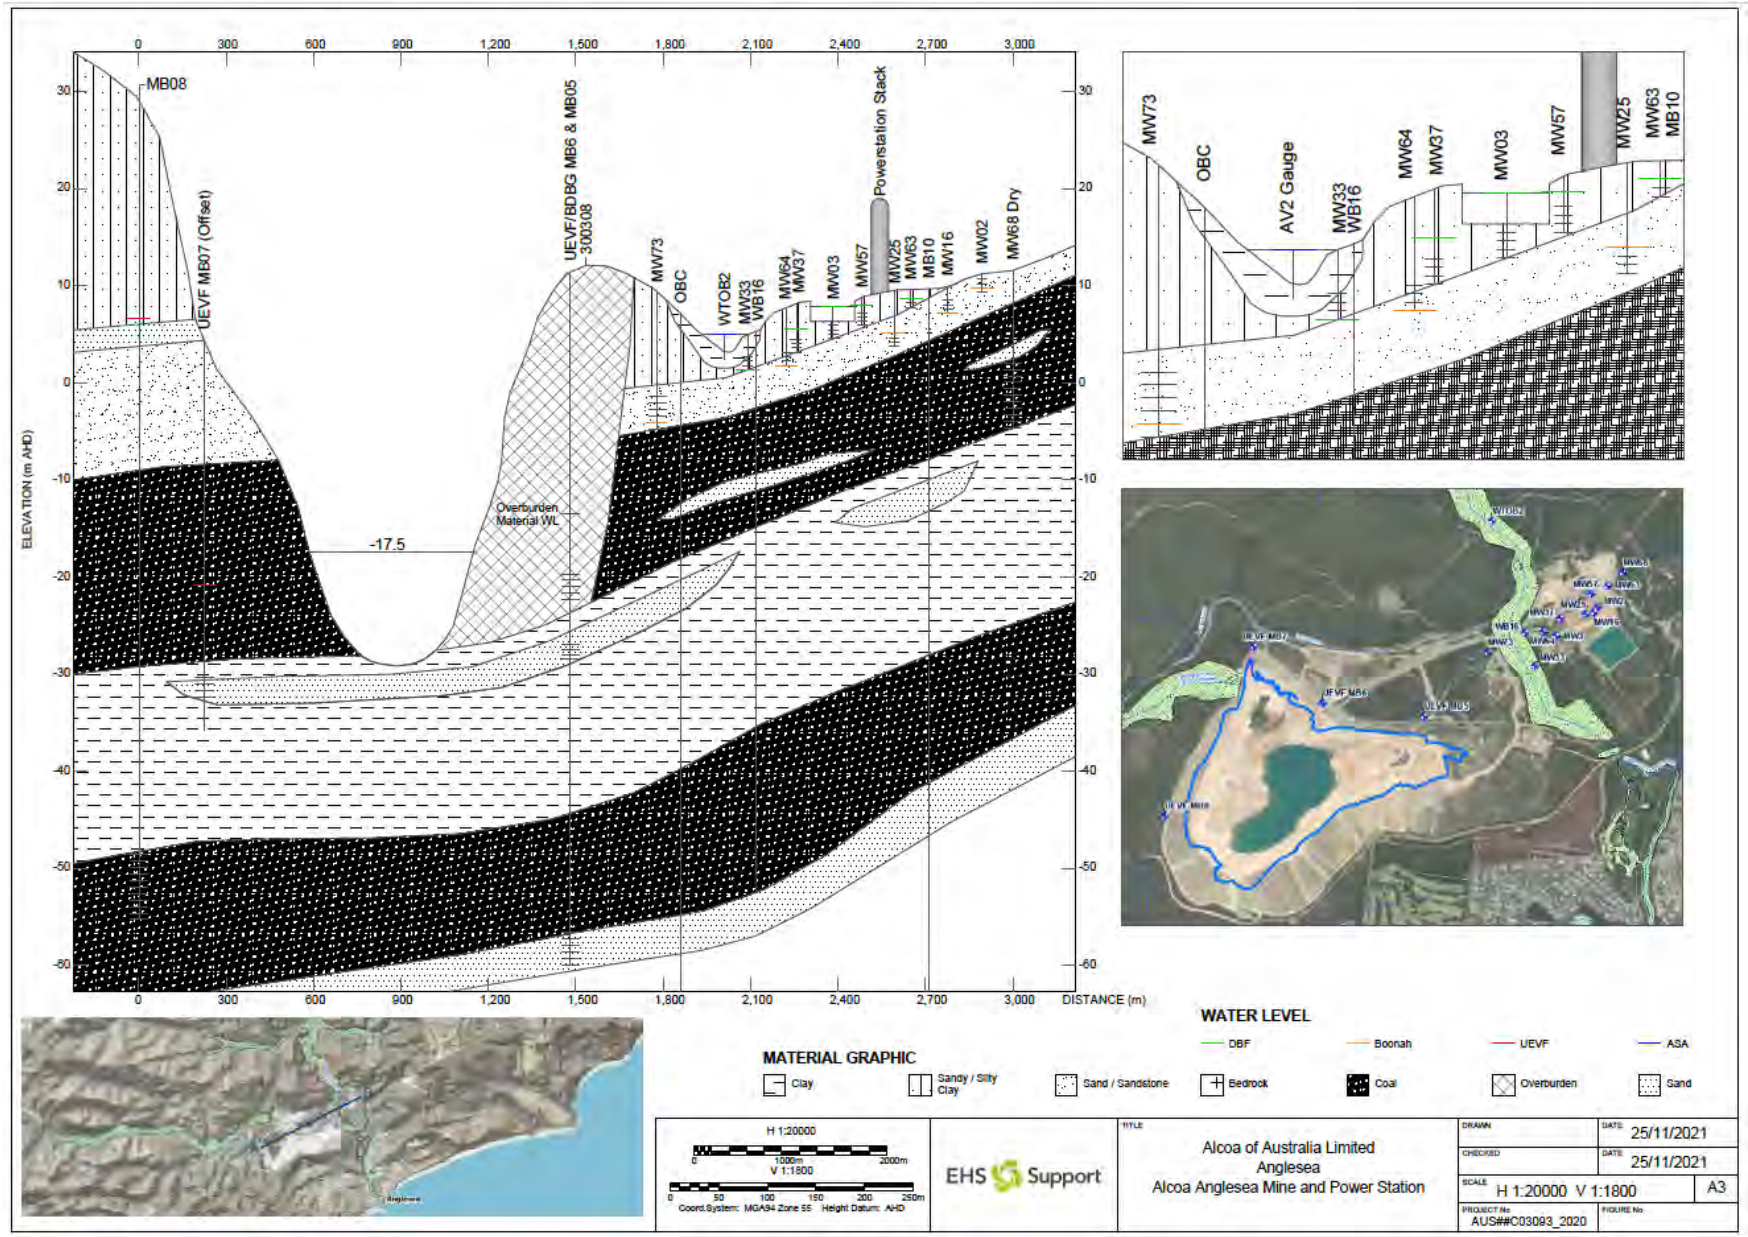

Figure 3-18 Mine Void Conceptualisation (Source EHS, 2022a)

3.11 Estuary Inflow

Historically, groundwater extracted from the UEVF production bores by Alcoa was used for process water and cooling water for the power station. The surplus (treated) process water was discharged to the lower Anglesea River and estuary under an EPA licence.

The estuary conditions have changed since 2016, primarily due to Alcoa ceasing to provide this consistent surface water flow into the estuary, in the order of 4 ML/day, from the power station.

Natural flows from the Anglesea Catchment are intermittent, and generally less than 50% of the time, and when flows occur the average is in the order of 2.9 ML/day (refer Table 3-1). During winter, when the estuary is relatively high, surface water is extracted from the estuary by Barwon Water, on behalf of DELWP, and stored in the former ash ponds adjacent the former power station. Barwon Water has an extraction licence for 126 ML/year. Stored water is then discharged back to the head of the estuary over the dry period to maintain water levels as directed by DELWP. GHD, 2021 recommended a base flow of 0.75−1 ML/day was required from December to June to maintain water levels in the estuary to reduce the potential for activation of acid sulfate soils in the artificial channels of Coogoorah Park. This minimal flow was aimed at compensating for the loss of freshwater inputs from the now-ceased mine discharge and to mitigate acidification impacts within the estuary.

It is noted that the influence of ASS in Coogoorah Park wetlands and channels is significantly less than the contribution from Salt Creek and Anglesea River (GHD, 2021). However, water level management reduces the risk of activation of ASS from Coogoorah Park in the estuary.

A conceptual model of changes in the ecological condition of the Anglesea River estuary is shown in Figure 3-19 (GHD ,2021). The model defines the changes from timing of the mine and power station discharge and the changes occurring to the estuary from:

- A reduction in freshwater flows from the catchment reducing water levels and over topping of the berm. This results in an increase in the height and width of the berm by wave action and coastal currents pushing sand further into the estuary.
- Reduced outflows from the estuary resulting in an increase in the height and width of the beach berm because of wave action and coastal currents pushing sand further into the estuary.
- Reduced buffering of moderate (5.5-7) pH catchment flows from mine and power station inflows.
- Estuary ecosystems communities transitioning to a freshwater dominated system.

The impact of the cessation of the Alcoa discharge, and the alkaline buffering capacity of the discharge, can be seen in Figure 3-20 (EHS, 2022a), the general decrease in the estuary pH since 2016 and particularly over the last 3 years.

It is noted that the estuary, like the lower portion of the Anglesea River, is hydraulically separated from the underlying main aquifers in the UEVF and LEVF. There may be the potential for some diffuse leakage from the water table aquifer towards underlying aquifers over time, however the DBF aquitard becomes thicker towards the coast providing an aquitard between the upper sand units of the UEVF and low permeability coals and the intermediate unit provide a further aquitard between the UEVF Lower Sand aquifer. Historical records of artesian conditions in the UEVF around the former power station provided further confirmation that the clay units overlying the UEVF aquifer were low permeability and confining (EHS, 2022a).

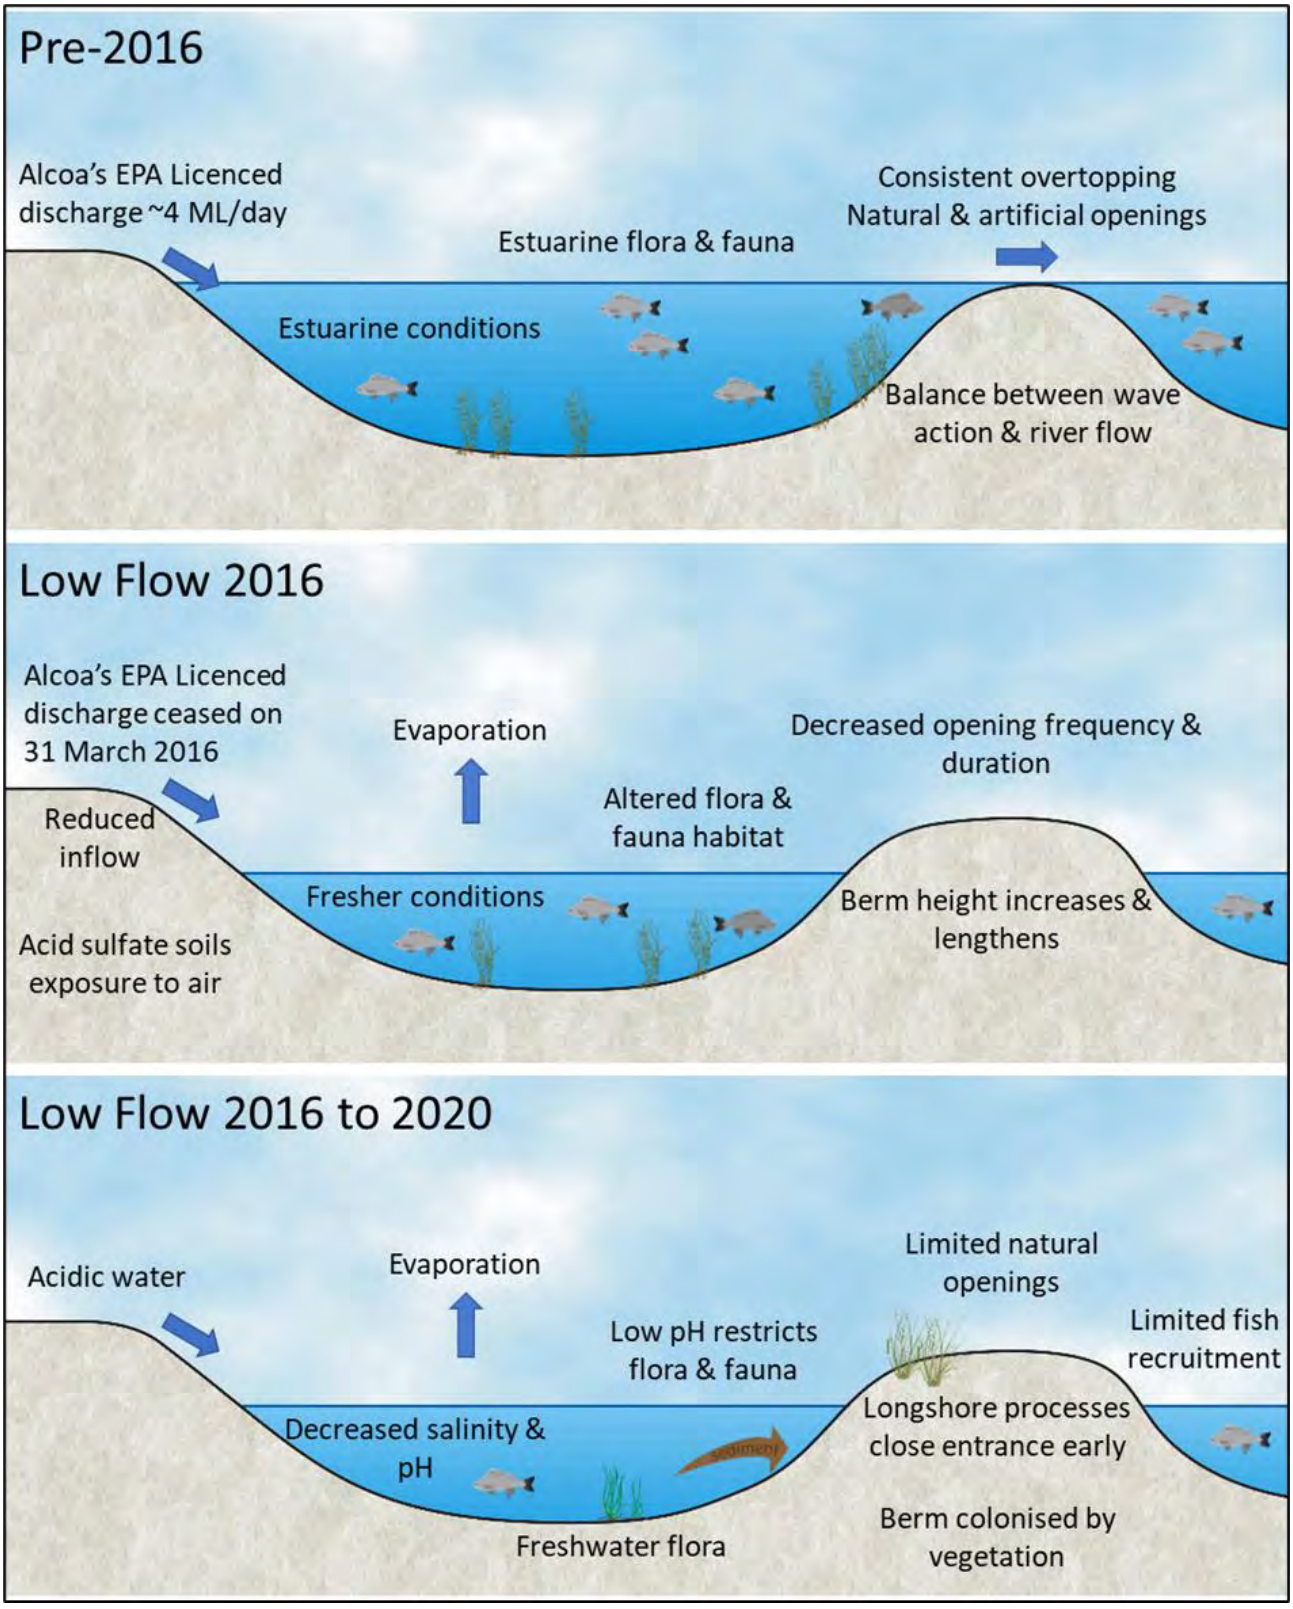

Figure 3-19 Conceptual model of changes in the Anglesea River estuary

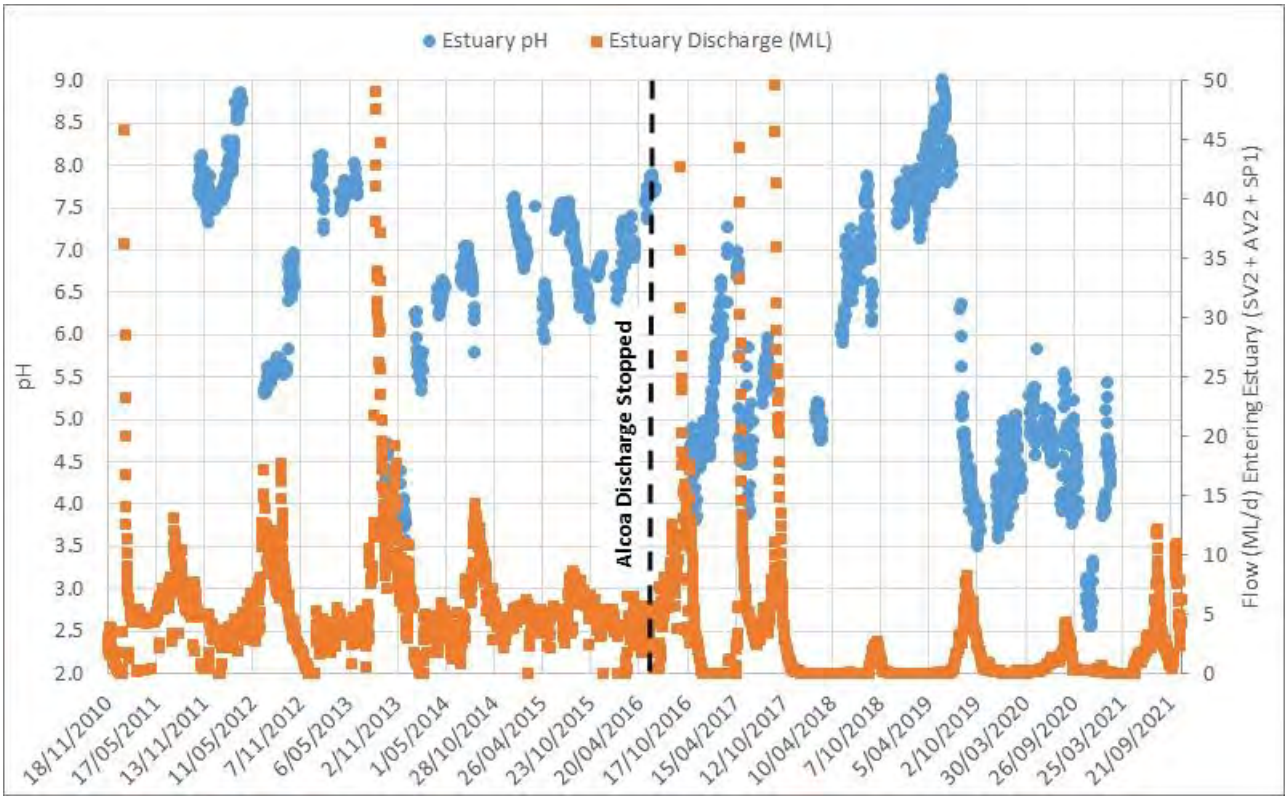

Figure 3-20 **Historical Surface Water Flows into the Anglesea River Estuary (Source EHS, 2022a)**

3.12 Regional Conceptual Hydrogeological Model

Consistent with GHD,2013a, and with reference to EHS, 2022a, the conceptual hydrogeological model for the region is presented in Figure 3-21 and the recharge and discharge processes are summarised in Table 3-7. In addition, the CHM is shown along a north-south cross section down the Anglesea River catchment, crossing from the Jan Juc Syncline to the Anglesea Syncline (Figure 3-22). Figure 3-23 graphically presents the conceptual model for the Alluvial Swamp aquifer.

Each process has been discussed in the previous sections and the numerical model will be used to quantify each of these parameters in the water balances.

Table 3-7 ***Summary of Aquifer Recharge and Discharge Processes***

Aquifer System	Recharge Process	Discharge Process
Alluvial Swamp aquifer	Direct rainfall infiltration	Evapotranspiration
	Runoff & Interflow recharge	Leakage to underlying formations
	Direct leakage from UEVF/LEVF aquifers	Swamp/Creek surface water outflow
	Baseflow (as stream inflow) from up-catchment	
Upper Eastern View	Direct rainfall infiltration	Offshore
	Runoff recharge (stream Infiltration)	Abstraction
	Upwards leakage from LEVF/ Downward leakage from overlying formations	Baseflow to Streams
	Leakage from mine void	Evapotranspiration
		Downward Leakage to the LEVF

Aquifer System	Recharge Process	Discharge Process
		During mining: Sump discharge/evaporation/storage in sediments removed Post mining: discharge to the pit waterbody /evapotranspiration
Lower Eastern View	Direct rainfall infiltration	Offshore
	Runoff recharge (stream infiltration)	Abstraction
	Downward Leakage from UEVF/MEVF	Upward leakage to UEVF
		Baseflow to Streams
		Evapotranspiration

4. Model Design and Construction

4.1 Software

The numerical groundwater flow model described in this report utilises MODFLOW-USG-Transport (version 2.1.0; Panday and others (2013) and Panday (2023)). This is a MODFLOW version that uses the Control Volume Finite Difference method, which allows for an unstructured model grid, as opposed to structured regular or irregular grids.

Features of MODFLOW-USG that are particularly suited to addressing the modelling needs and objectives of this study include:

- Robust handling of dry cells, via MODFLOW-USG's upstream weighting option, which operates in a similar way to other MODFLOW codes including MODFLOW 6 and MODFLOW-NWT.
- This is important in this case for several reasons. First, outcropping or near-surface model cells are expected to become desaturated in places in response to variable climate and historical mining operations. Second, some deeper model cells may become desaturated, with shallower cells remaining saturated, such as those in the Anglesea and Salt Creek swamplands around Alcoa's historical mining operations. It is important that the model be capable of passing vertical leakage from the base of the alluvial/swamp aquifer down through any desaturated layers, and ultimately to the next (fully- or partially-) saturated deeper layer. MODFLOW-USG with its upstream weighting option is capable of this.
- Flexible meshing (as a means of model domain discretisation), utilising a range of cell shapes and levels of refinement. This allows model cells to closely follow the geometry of features of interest, e.g., stream channels, swamps, mine pits and the coast.
- Efficient local mesh refinement around features of interest within the large regional model domain required of this study, whilst retaining larger cells elsewhere. The ability to simulate local mesh refinement within a large regional domain provides smaller, faster models, without compromising resolution in areas of interest. This has flow-on benefits in terms of more robust and efficient history-matching and uncertainty analyses.

Model boundary conditions capable of simulating the following features to a level of detail adequate for the objectives outlined in Section 2.1:

- Stream flow routing and its interaction with groundwater (the Stream Flow Routing (SFR2) package; see Niswonger and Prudic (2005), and Panday and others (2013)); and
- The Alcoa mine pit water body and its interaction with groundwater and creeks (the Lake (LAK3) package; see Merritt and Konikow (2000) and Panday and others (2013)).
- Highly efficient numerical methods, which contribute to more robust and efficient history-matching and uncertainty analyses.
- An expansive, regularly updated, regularly expanded family of open-source support tools for pre- and post-processing, and for providing linkages with the uncertainty analysis and optimisation codes used in this report.
- A mature and stable open-source (i.e., transparent and reproduceable) code base[7].
- The code is free – there are no expensive licences required, nor the associated licensing issues with running many models across many computers, as is required in a modelling workflow such as that outlined in this report.

Furthermore, the requirement for using the model to estimate the maximum extent of pit water body water migration into the groundwater system (Section 2.1), particle tracking can be undertaken on unstructured MODFLOW-USG models using the code mod-PATH3DU (Muffels and others (2020)).

Details on how MODFLOW-USG is applied are provided in the following sub-sections.

[7] https://www.gsienv.com/product/modflow-usg/

4.2 Modelling units and spatial projection

The groundwater flow model uses units of metres and days. The geographic coordinate system used is the Geographic Datum of Australia 1994 (GDA94), and the projection used is the Map Grid of Australia (MGA) zone 55 (EPSG WKID 28355).

4.3 Domain and Spatial Discretisation

The model domain and mesh discretisation are presented in Figure 4-1. The domain extends approximately 38 km by 26 km in the southwest-northeast and northwest-southeast directions respectively (Figure 4-1). It covers a 570 km^2 area, broad enough to allow simulation of potential groundwater and surface water effects from future Barwon Water and Alcoa groundwater use and mine rehabilitation activities without undue interference from model boundaries. Therefore, the domain extends some distance offshore – to avoid near-shore pumping interactions with a coastal model (head) boundary located along the shoreline. It also covers the geological extent of the key units in onshore areas for the same reason.

The domain has been laterally subdivided into a maximum of 48,525 variably sized Voronoi-shaped model cells in any one layer (Figure 4-1), and vertically subdivided into 12 layers, which are detailed in Table 4-1. These are shown in cross section view in Figure 4-2, and as thickness maps in Figure 4-4 through Figure 4-7. All layers extend over the entire domain (i.e., a 12-layer stacked mesh of 48,525 cells is used) resulting in a total number of model cells of 582,300. This is on the large side for the computing demands of modern history-matching and uncertainty analysis methods, however, many of these cells have been inactivated in the numerical solution because geologically all layers do not exist across the entire domain (they pinch out); this leaves only 261,559 active cells, which is a more practicable number given computing demands.

The reason for using a stacked mesh across all layers is that this is a requirement of MODFLOW-USG's LAK package (see Section 4.5.9); if this package were not used, the pinched-out model cells could be removed entirely from the model files. Given the inclusion of pinched out cells in the model files, the MODFLOW-USG Discretisation (DISU) package file is modified such that each active cell that is underlain by an inactive (pinched-out) cell is vertically connected down to the next active underlying cell. In addition, nodal connection lengths are adjusted accordingly, reciprocal (upward) connections are made, and connections to inactive cells are removed.

The model top (land) surface is defined using the Victorian Government's Vicmap Elevation DEM 10m (a hydrologically enforced 10 m resolution Digital Elevation Model with respective horizontal and vertical accuracy of 12.5 m and 5 m or better (DELWP, 2020a)). This is averaged across each variably sized model cell (based on the intersection of raster cell centres with model cell polygons), and hence this accuracy is variably maintained in the numerical model, with lower accuracy in large cells away from areas of interest, and higher accuracy in finer resolution cells in areas of interest.

The model mesh is refined as follows:

- Within the historical mining activity area, aligned with different pit development activities over time. This also results in a high level of refinement (20-50 m cell sizes) around the existing and future pit water body.
- Alcoa and Barwon Water groundwater abstraction bores, and ASA observation bores (approximately 5 m at the bore).
- Along creeks and rivers. Compared with other creeks, greater refinement (50 m long by 25 m wide) is implemented along the Anglesea River, Salt Creek, and their tributaries, because these are the key potential impact receptors of Alcoa and Barwon Water activities.
- Within swamps and alluvial deposits, model cells are sub-100 m resolution, and often much finer.

The mesh is also broadly aligned with other selected feature boundaries, such as the coastline and MEVF outcrop locations, which also mark the outcrop boundaries of the two important UEVF and LEVF aquifers.

Around the Alcoa Area of Interest (AOI), which is local to the Alcoa coal mine, more detailed mapping of hydrogeological units is available based on mine borehole data. These detailed AOI sub-layers are extrapolated out from the AOI as follows:

- The Boonah Formation (model layer 3) is extended to the coast, with the coastward thickening evident in the AOI mapping and as described by Holdgate and others (2002) extrapolated, broadly following the morphology of the directly underlying and closely related UEVF coal sequence in the Anglesea Syncline, as mapped by Holdgate and others (2002).
- The UEVF main coal (model layer 4) and UEVF upper sands (model layer 5) are relatively thin and pinched out around the margins of the AOI mapping.
- The UEVF (intermediate coal; model layer 5) is extended regionally across the entire UEVF extent. Within the AOI, Alcoa's detailed mapping is used to define this surface. Beyond the AOI, this unit is extrapolated using its proportion of total UEVF (intermediate) plus UEVF (lower sands) thickness mapped within the AOI. That is, this proportion is used to subdivide the total UEVF thickness in areas beyond Alcoa's AOI. A smooth (interpolated) transition between the AOI and surrounding areas is implemented, rather than a sharp boundary.

Including greater vertical discretisation through sub-layering in this area is advantageous over the simpler (more lumped) layering system of GHD (2013) for several reasons, including:

- Groundwater monitoring and pumping bores screen specific sub-layers within the broader ("bulk") UEVF and overlying formations in this area, for example the Boonah Sands, the UEVF upper sand, and the UEVF lower sand. There is important information in these sub-layer-specific groundwater data with respect to interactions between groundwater, the historical open cut coal mine, and the rehabilitated pit water body. The model can only be trained to that important information if the model is discretised to an appropriate level of detail.
- The ability to simulate vertical gradients within the bulk UEVF beneath the historical coal mine and rehabilitated pit water body.
- The ability to simulate the effects of sub-layers of differing hydraulic properties, and potentially differing water qualities, on groundwater interactions with the pit water body as its levels rise and fall.

Table 4-1 Groundwater Model layer summary

Group	Formation	Member	Model HGU code	Model Layer	Layer name	Other details
	Qa Alluvials / swamp peats		1	1	Swamp / Alluvial (ASA) Aquifer	
Demons Bluff Group	Anglesea Formation		2	2	Demons Bluff Formation (DBF)	
	Salt Creek Formation					
	Boonah Formation		20	3	Boonah Formation	These are sub-layers that are extrapolated out to varying degrees from the Alcoa AOI. See report text for details.
Eastern View Group	Upper Eastern View Formation	A Group coals	31	4	A Group coals & basal clay	Layer 4's basal clay is thin (1-4 m thick), not found everywhere, and not consistently mapped (see EHS, 2022a). Where it is recorded in logs it is included with the A group coals layer. The A Group coals are up to 45 m thick (EHS, 2022a). Spatially variable vertical hydraulic conductivity of layer 4 is used to allow for the presence of the basal clay, as inferred through observation data and the model history-matching process. A discrete basal clay layer is considered unnecessary complexity, given that: 1. There are no groundwater monitoring data on either the basal clay or the A Group coals. 2. The basal clay will act as the flow-retarding stratigraphic unit within this layer, dominating the vertical conductance term in this layer (i.e., the coal is likely to be of higher permeability). 3. Its small thickness relative to that of the A Group coals means that it would contribute very little reduction in transmissivity of this layer.
		Basal clay				
		UEVF upper sand	32	5	UEVF Upper	
		UEVF intermediate sand, coal, clay	33	6	UEVF Intermediate	
		UEVF lower sand	34	7	UEVF Lower	
	Middle Eastern View Formation		4	8, 9, 10	MEVFa, MEVFb, MEVFc	Split across three layers in subcrop for simulation of vertical gradients LEVF→UEVF. One layer in outcrop.
	Lower Eastern View Formation		5	11	LEVF	

Group	Formation	Member	Model HGU code	Model Layer	Layer name	Other details
Otway Group	Otway Group		6	12	Bedrock	Limited extent on western margin, approximately 50 m at its thickest (western) wedge, thinning to nil approximately 5 km to the east of the western model boundary.

4.4 Temporal Discretisation and Numerical Solver

Temporal model discretisation for the history-matching model is as follows:

- A single initial steady state stress period to provide initial conditions for the subsequent transient stress periods. Prior to development of the Alcoa coal mine in 1969, groundwater abstraction from the Jan Juc GMA is understood to have been minimal and hence starting conditions for the transient run were created from a steady-state simulation using long-term average recharge and assuming zero groundwater abstraction.
- 323 transient stress periods of variable duration, depending on observation data density and hydrologic stresses and change during different time periods. These cover the period from January 1969 through to the end of March 2023. Details of and rationale for stress period durations are shown in Figure 4-8. When flow gauges record peak stream flow (and recharge) events, stress periods are refined to monthly to half-monthly scale. During drier periods when there is little hydrological variability, and/or when there are limited temporally detailed observation data or hydrological change (e.g., change in borefield pumping rates), stress period durations are increased up to quarterly, or even annual further back in time towards the start of the simulation when data are very sparse. This approach provides faster-running models, which aids in history-matching and uncertainty analysis workflows, whilst not compromising the ability of the process to extract as much information as possible from the observation data, with respect to model parameters and their uncertainty.

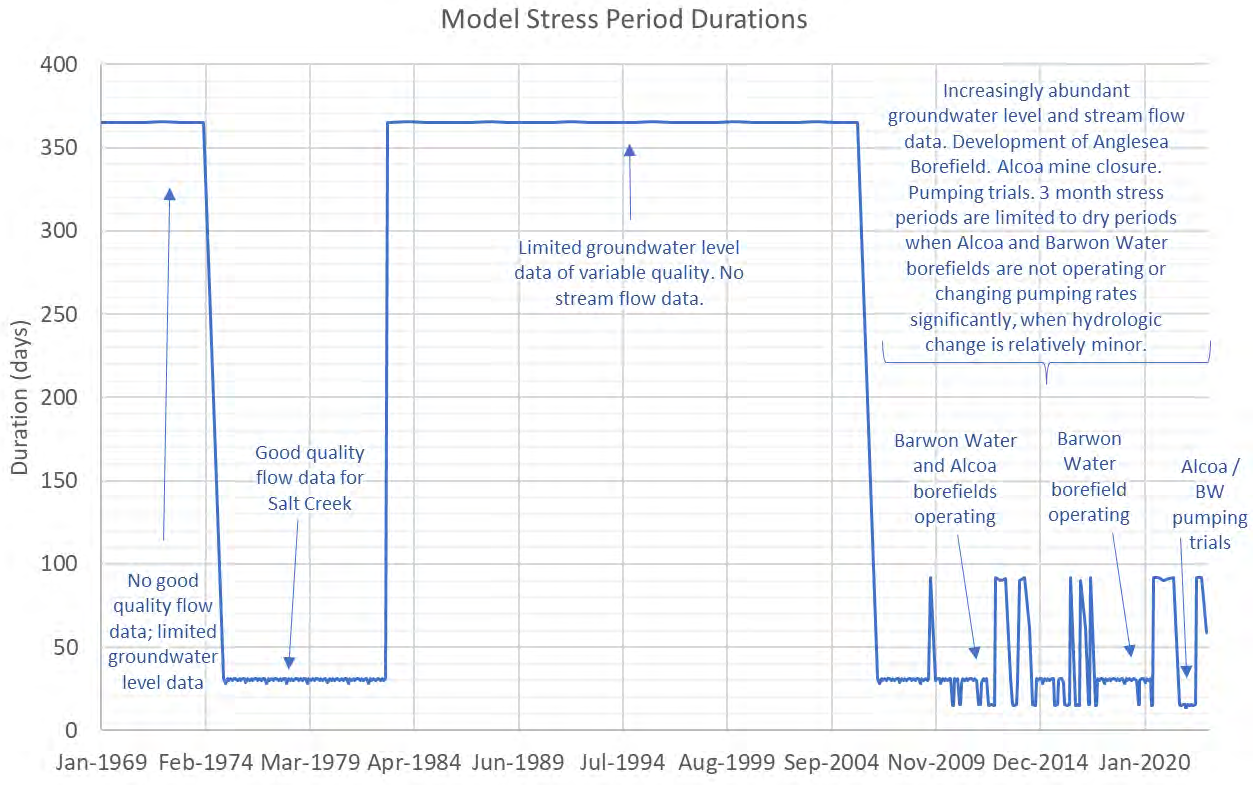

Figure 4-8 Model temporal discretisation details

Predictive models use initial conditions from the end of the transient historical model. Temporal discretisation will be confirmed in predictive model reporting that will be provided when that work is undertaken, after model history matching is completed.

Each stress period is subdivided into two time-steps, except for annual stress periods which are subdivided in three. Adaptive time stepping is however applied where numerically required to provide convergence. Outer iteration head closure tolerance is set to 0.001 m for the steady state model, and 0.01 m for the transient model. These were increased for the purposes of PESTPP-IES to 0.01 and 0.1 respectively, with no resultant increase in water balance closure error, yet appreciable gains in simulation run times; they could be reduced if desired for subsequent modelling if this is considered important. MODFLOW-USG's Sparse Matrix Solver (SMS) package is applied, with the unstructured Preconditioned Conjugate Gradient (PCGu) linear solver. Newton iterations and backtracking are activated.

4.5 Boundary Conditions and Applied Fluxes

4.5.1 Anglesea Estuary

The Anglesea Estuary is simulated using MODFLOW-USG's River (RIV) package (Figure 4-9). This is a head- and conductance-dependent flux boundary:

- When groundwater levels rise above the defined stage elevation, groundwater discharges into the RIV boundary, as a linear function of groundwater level-stage difference and boundary conductance.
- When the groundwater level is above the defined boundary bottom elevation (estuarine bathymetry) but below its stage, the flux to the boundary from groundwater is a linear function of the head difference between the boundary and groundwater levels, and boundary conductance. Bathymetry was defined through topographic interpolation from the project DEM surrounding the estuary.
- Although unlikely to occur in this model, a constant maximum loss term is applied when the groundwater level in the model cell to which the RIV boundary is applied falls below the specified base (bathymetry) of the river. At these times, the loss term is a function of the boundary stage, bottom elevation, and conductance.

The hydraulic conductivity term of RIV conductance was initially set to 0.01 m/day, and a 1 m thick bed material was assumed. This is adjusted during history-matching. Cell areas (which vary) were used to define the remainder of the conductance terms. RIV stage is defined using the observed mean freshwater head sea level of 0.1 mAHD, assuming 1 m depth; see Section 4.5.2. This stage height will be varied during predictive modelling, using the forecasts of potential future sea level rise described in Section 4.5.2.

4.5.2 Coastal Boundary

The location of the fresh-saline groundwater interface within the aquifers and aquitards along the coast and offshore is unknown. Based on the projection of groundwater contours, Hancock (1967) estimated this to be at 3,500 m from the coast in the UEVF, which is in the vicinity of the Torquay Fault.

In the Gippsland Basin's offshore area, a very similar related geological sequence, within the equivalent aquifers of the Eastern View Group (the Latrobe Group), the fresh-saline interface has been mapped as being located up to 70 km offshore, with a broad mixing zone on the landward side between 30- and 70 km offshore (Lawrence, 1992; Post and others, 2013).

Freij-Ayoub and others (2007) mapped the freshwater equivalent potentiometric surface for the pre-offshore development period of the offshore Gippsland Basin's Upper Latrobe Group; this indicates that the freshwater flow system would result in upward diffuse discharge of fresh water to the ocean from deep confined aquifers in the central parts of the offshore basin up to as far as 25-50 km offshore. In hydrostratigraphic units at shallower depths, the fresh-saline interface would be located progressively closer to the coastline (Post and others, 2013). Similar offshore groundwater system behaviour may be reasonably expected in the Anglesea area, albeit possibly closer to shore, at least in the UEVF, as suggested by Hancock (1967).

The offshore area in the Anglesea groundwater model is simulated using MODFLOW USG's General Head Boundary (GHB) package (Figure 4-9). This operates in a very similar way to the RIV package described in Section 4.5.1, except that the maximum loss term is not applied; gain and loss from and to groundwater is a constant linear function of the head difference between boundary stage, groundwater levels, and boundary conductance.

GHBs are applied to all outcropping (surficial) layer cells in the offshore area – in this case, these are all in model layer 2 (DBF). GHB stage varies from 0.080 to 1.46 mAHD – approximately reflective of mean sea level[8], as corrected for the density of seawater over the mapped offshore bathymetric depth, which varies from 0-50 m. These boundaries extend 5-7 km offshore. The sensitivity of selected forecast model outputs to likely future sea level rise will be assessed using the very high greenhouse gas scenario (RCP8.5) projections for the Surf Coast (median estimate of 0.24 m rise at 2050 relative to the 1986-2005 average)[9].

Beneath these GHB cells in other layers, no boundary conditions are applied, but groundwater flow is simulated through them. At the furthest offshore (south-eastern) edge of the model, a no flow boundary is applied in all layers. This forces groundwater flow within the model domain in the offshore area up into the surficial GHB cells representing the overlying ocean, as controlled by the vertical hydraulic conductivity of the layers underlying the offshore area, and the GHB conductance and stage. These parameters are adjusted during history-matching, given the largely unknown nature of the fresh-saline interface. This design reflects the observations from the Gippsland Basin and Hancock (1967) noted above, whilst acknowledging and accommodating the fact that the behaviour of groundwater in the offshore area is uncertain.

The hydraulic conductivity term of GHB conductance was initially set to 0.01 m/day, and a 1 m thick bed material was assumed. Hydraulic conductivity is adjusted during history-matching. Cell areas (which vary) were used to define the remainder of the conductance terms.

4.5.3 Western Boundary Otway Group Bedrock

The western margin of the Otway Group bedrock (model layer 12) is also assigned GHB boundaries (Figure 4-9). GHB head is defined as 5 m below ground surface and is not adjusted during history matching. GHB conductance is only implicitly made adjustable during history-matching, through the explicitly adjustable hydraulic conductivity of layer 12 being used to calculate conductance, along with an assumed length term of 1 m, and lateral cell face areas.

[8] 0.077 mAHD given a gauge zero elevation of -1.423 mAHD and mean gauged level of 1.5 m. See: http://www.bom.gov.au/ntc/IDO71056/IDO71056SLD.shtml and http://www.bom.gov.au/ntc/IDO50000/IDO50000_60790.pdf
[9] https://coastadapt.com.au/sea-level-rise-information-all-australian-coastal-councils#VIC_SURF_COAST

4.5.4 Northern Boundary

Much of the northern model boundary is defined by a major river valley filled with alluvium, is generally a topographic low point, and is hence considered a net discharge area. Model layers in this area are generally thin, often close to or at minimum thickness (see figures discussed in Section 4.3). The geology in this area is not well explored and therefore not as deeply understood as in areas to the south. It was found during earlier model runs that groundwater was artificially building up against this boundary, particularly in deeper layers, because of the low permeability MEVF and DBF layers; this seemed to cause numerical difficulties and slow model run times, and it adversely affected history match quality to the BW ASR bores to the south.

On this basis, the northern model margin is assigned Specified Gradient Boundaries (SGBs) in all layers (Figure 4-9). SGBs are useful in that groundwater head along the boundary condition is naturally computed on a transient basis by the model given aquifer properties and recharge (and other input forcing) dynamics, which continually change during history matching. That is, groundwater levels do not need to be defined as they do for head-based boundary conditions. This is considered an appropriate approach along this boundary given the relative lack of geological and groundwater level data in the area.

SGB gradients are initially defined as -5e-4 (m/m; negative values meaning out of the model) and are adjusted during history matching using spatially varying pilot points, with an allowable range of -1e-5 to -5e-3 m/m. The area component of the SGB input term is computed as cell thickness multiplied by the square root of the cell surface area; this does not change during history matching.

4.5.5 Groundwater Recharge

For the purposes of estimating groundwater recharge for input to the groundwater model, in addition to runoff and interflow (“quickflow”) to modelled streams, the one-dimensional soil moisture model PERFECT (Littleboy and others, 1989) is applied. Although PERFECT has typically been used for agricultural applications, and occasionally land use change (reforestation or clearing) studies, in this case it is used in its simplest form – the “crop factor model”.

This simple approach is used to provide an assessment of recharge and quickflow variability given climatic variability and its effect on soil moisture deficits, for a groundwater-focussed model of temporal discretisation that is relatively coarse compared with surface water-focussed models. For the purposes of this study, whatever approach is taken to estimate these hydrologic components should preferably be fast-running, adjustable through history matching, and sufficiently flexible to facilitate observed groundwater level and stream flow variability simulation to a level of temporal and spatial detail commensurate with the model’s intended purposes (Section 2.1).

PERFECT simulates near-surface water balance components. It partitions effective rainfall into components including surface runoff, movement through soil moisture stores, soil water uptake by vegetation, and deep drainage from the soil profile. A schematic overview of PERFECT and its linkages to the groundwater model of this study is presented in Figure 4-10.

In this case, the simplest vegetation water use model offered by PERFECT was used, the “crop factor model”. The crop factor model estimates transpiration using a user-defined annual (monthly) distribution of green cover, pan evaporation, and a crop factor. Transpiration is then removed from individual layers of the soil profile using a generic root penetration and density equation. See Littleboy and others (1989) for further details.

PERFECT estimates runoff using a modified form of the US Soil Conservation Service’s (SCS) runoff curve number method; to summarise, this applies a higher curve number when vegetation cover is lower (see Littleboy et al, 1989 for details).

As is shown in Figure 4-10, a proportion of deep drainage from PERFECT is diverted laterally to streams as interflow. This is estimated external to PERFECT using the method of Rassam and Littleboy (2003), and the remaining deep drainage is applied to the groundwater model as watertable recharge. The Rassam and Littleboy (2003) method uses topographic slope and the ratio of upper to lower soil horizon permeability to estimate the fraction of deep drainage that is diverted laterally within the unsaturated zone as interflow; the steeper the slope, and the higher the upper soil horizon permeability relative to that of the lower soil horizon, the greater the proportion of deep drainage from PERFECT that is diverted laterally to streams as interflow, along with the runoff, which are together defined as "quickflow" here; this is also described further in Section 4.5.8.

Sources of input data for the PERFECT models are outlined as follows:

- Rainfall and pan evaporation data are from the SILO patched point data service[10], which provides temporally infilled and extrapolated climatic data at all available gauges across the model domain. This is augmented by two Barwon Water-owned rainfall gauges (235805 at AARC and the 235806 at Breakfast Creek). Rainfall records at these gauges were interpolated to the full period of other SILO data (1950 to current) using the highest quality monthly total rainfall linear regression with all SILO gauges, which is the closest SILO gauge (87119) in both cases (Appendix A). The regression-derived estimates of total monthly rainfall were disaggregated to daily scale according to the distribution of daily rainfall across each month at gauge 87119. Pan evaporation data for the two Barwon Water's gauges, also required by PERFECT, was taken directly from gauge 87119 because no pan evaporation records are available for the Barwon Water's gauges.
- Soil hydraulic properties and estimates of allowable upper and lower bounds for the purpose of model history-matching are from the Soil Hydrologic Properties of Australia data set (Western and Mackenzie, 2004).
- An additional bottom soil horizon was added to these soil profile data where aquitards and poorly permeable aquifers (DBF, MEVF, bedrock) are modelled to occur at outcrop; this bottom horizon is given the same properties of that of the SHPA data set, except for vertical permeability, which is adjustable during history matching and uncertainty analysis. The reason for doing this is to avoid excessively high recharge rates being applied to groundwater model aquitard layers, which is both unrealistic and numerically challenging.
- Initial runoff curve number values and allowable ranges for use in history-matching were obtained from USSCS (1989), for grassed and forested land.
- Monthly average LAIs are taken from the CSIRO data set described in Lu and others, 2001.

One PERFECT model is built and run for the combination of soil types (including outcrop aquitard layers), land covers, and climate gauges[11] mapped across the model domain (Figure 4-11). This equates to a total of 237 PERFECT models. Each model uses the three nearest climatic time series from the SILO / Barwon Water data. Data from the three nearest gauges are linearly interpolated to the centroid of each PERFECT model polygon, with weights initially set using linear distance between each gauge and the centroid; these weights are however adjustable during history matching, to account for the potential local dominance of one more distal gauge over the closest. The interpolated time series is then scaled by the Bureau of Meteorology's (BoM's) long-term average rainfall distribution map for 1980-2010 resampled to 10 m resolution[12]. For each mapped polygon, this scaling is implemented using the ratio of the BoM's mapped average rainfall with the corresponding period average rainfall interpolated from the three relevant climate gauges. This introduces greater accounting for local-scale topographic effects on spatial climate (and runoff/recharge) variability.

[10] https://www.longpaddock.qld.gov.au/silo/

[11] Climate gauge zones are mapped as theissen polygons around each gauge across the model domain. Linear spatial interpolation is conducted, using the three nearest climate gauges, for each PERFECT model polygon within each theissen climate polygon. The linear interpolation (weighting) factors between these three gauges are adjusted during history-matching, in recognition of uncertainty in which gauge is most representative of climatic conditions within each PERFECT model polygon.

[12] http://www.bom.gov.au/jsp/ncc/climate_averages/rainfall/index.jsp?period=an&area=vc#maps. The BoM data are provided on an approximate 4.5 by 5 km resolution grid. Given that this is quite coarse compared to the scale of significant topographic (and by implication climatic) variability across the model domain, ArcGIS's Empirical Bayesian Kriging (EBK) Regression tool was used to resample the BoM grid to the 10 m resolution of the project DEM. This tool uses the project DEM as a secondary (regression) variable that is known to influence spatial rainfall variability. Inspection of the BoM rainfall map confirms this.

Each PERFECT model simulates the near-surface water balance on a daily time step from 1960 through to January 2022 for different sets of climatic sequences, land cover, soil type and topographic slope. Once each PERFECT model is run, interflow is estimated based on topographic slope and vertical soil hydraulic conductivity contrast as per Rassam and Littleboy (2003). Example output recharge and quickflow timeseries are shown in Figure 4-12 to illustrate their variability.

Recharge and quickflow data from these models, which represent initial estimated recharge and quickflow within each soil type, land use, and climate gauge combination, are then spatially aggregated and applied to groundwater model cells (RCH package) and stream or water body boundary conditions (SFR2 package reaches and LAK3 package lakes; see Sections 4.5.8 and 0).

Spatial scaling of applied recharge is implemented at the groundwater model cell scale, accounting for the finer cell resolution (and therefore topographic and climatic variability) relative to that represented by the PERFECT models (i.e., soil and land cover combination polygons). This is done as follows:

1. Using annual deep drainage (recharge plus interflow)[13] versus rainfall linear regression statistics from the initial PERFECT models. The regressions suggest an approximate 64% change in annual deep drainage relative to changes in annual rainfall (this is mean of the linear regression slopes presented in Appendix A, limited to those with correlation coefficients of at least 0.75); for example, a mapped 100 mm/year rainfall difference between one area and another is estimated to result in a 64 mm/year deep drainage reduction. A similar regression approach was investigated for runoff, but this was abandoned due to comparatively poor correlation between rainfall and runoff changes (see Appendix A and Section 4.5.8 for details).
2. Scaling via interpolated pilot point multipliers, with initial values of 1. These allow for the model history matching and uncertainty analysis processes to adjust the initially estimated spatial recharge (and interflow) variability, as informed (or not) by the available observation data.

In historically mined areas, land cover is modelled to change from vegetated to cleared condition from the onset of mining, and back to vegetated condition at the onset of pit backfilling. Spatial mapping and dates of mining and backfilling operations were provided by Alcoa. During mining, recharge is directly applied to the model layer containing the mined seam (typically model layer 4); at other times (and in all other areas), it is applied to the upper most active layer.

For the purposes of defining recharge rates to the initial steady state model stress period described in Section 4.4, PERFECT's estimates from 1960 through 2023 are applied (excluding mined land cover models). A single model-wide scaling factor of these recharge rates is then applied and made adjustable during calibration. This is in recognition of the initial stress period's potentially important but unknown abstract role in defining initial conditions for the subsequent transient stress periods. In effect, the steady-state stress period is an abstract representation of past climate that has led to the initial transient groundwater conditions in 1960, setting the transient period up for its pre-conditioned response to subsequent climatic variability.

4.5.6 Climate Change Sensitivity Scenarios

The adopted approach to runoff and recharge estimation for this project provides a suitable basis from which forthcoming predictive modelling can be undertaken whilst considering potential future climate change effects. DELWP (2020b) provides guidance around approaches to such scenarios for both stream flow and groundwater recharge. This is summarised as follows:

Use two historical climate reference periods as a basis for future rainfall, runoff, and recharge projections:

- The post-1975 reference period; and
- The post-1997 reference period.

[13] Recharge plus interflow (deep drainage) is used because recharge and interflow are both derived from the same PERFECT output (deep drainage). Therefore, the same scaling factors (per change in rainfall) apply equally to recharge and interflow.

- The post-1997 reference period is directly applied to the recharge/runoff models, without any ongoing or future climate changes, i.e., Global Climate Model (GCM) projections are not used, and this scenario represents a step change that started in 1997. If longer simulation periods are required, longer historical data sets can be adjusted to match the statistical properties of the post-1997 period using percentile-based scaling.
- The post-1975 reference period is scaled according to the RCP8.5 (conservative) GCM-projected changes between 1995 and the year of interest, assuming a linear progression over time between the GCM time slice projections for the Otway Coast as presented by DELWP (2020b). For example, to model the medium-term climate (over the next 25 years), the 1975-2000 climate (rainfall and potential evapotranspiration) sequence used as input to the PERFECT models is scaled by the GCM-projected changes between 1995 and 2047 (i.e., 25 years beyond 2022), using a linear interpolation between the GCMs' 2040 and 2065 projections. For evapotranspiration under the medium climate change projection, this would be a 4.5% increase (3.7% in 2040 to 6.4% in 2065); for rainfall, this would be a -3.9% change (-3.6% in 2040 to -5.8% in 2065). These factors would be applied directly to the 1975 to 2000 climate sequence before application to the PERFECT models.

Figure 4-12 Example preliminary PERFECT mode outputs for selected soil types and land covers

4.5.7 Evapotranspiration from Groundwater

Evapotranspiration from groundwater is modelled using MODFLOW-USG's EVT package. This simulates uptake of groundwater through evaporation and transpiration, from within a defined "extinction depth" below the defined "evapotranspiration surface" (normally defined as the land surface, or top of the model). A simple linear function of the extinction depth is used to take evapotranspiration from groundwater at a linearly declining rate with depth. The user-defined maximum rate is applied when groundwater levels are at or above the defined evapotranspiration surface, and this rate is linearly reduced to zero as groundwater levels fall to or below the extinction depth.

The applied maximum rate was defined as pan evaporation ***minus*** the near-surface actual evapotranspiration modelled by PERFECT ("PE-AE"). Spatial aggregation from PERFECT to groundwater model cells is as described for recharge in Section 4.5.5. However, further spatially variable adjustment of the estimated maximum EVT rates is implemented using pilot points and kriging (via PLPROC's calc_kriging_factors_auto_2d function; see Doherty, 2016c and Doherty, 2003). These EVT adjustment factors are initially set to a value of one but can vary from 0.5 to 1.2 during history matching; this range remains consistent in the post-history matching (optimised) parameter realisations (see Section 6.1.7 and Figure 6-32).

Applied extinction depths are initially set to values of 5 m for natural areas outside of the swamps (a mix of heath, eucalypt, and many other species), 2.5 m for swamp and alluvial areas (mixed species but largely melaleuca scrub), and 1 m for areas of pasture. Allowable extinction depth ranges for history-matching are set wide however, in recognition of the wide variety of landscapes and vegetation within the domain, and the inherent variability and uncertainty of this parameter. These ranges are loosely based on the global data of Canadell and others (1996) and Fan and others (2017) and are outlined in Table 4-2, recognising that:

- There are no known Anglesea-specific species rooting depth or water use data.
- The strong sensitivity of rooting system depth to local topographic, soil, climatic and hydrologic conditions (see Fan and others, 2017).
- The heavily simplified representation of saturated zone evapotranspiration in MODFLOW-USG.
- The same set of pilot points as is used to scale the maximum EVT rate are also used to spatially scale extinction depths across the domain during history-matching.

Table 4-2 Maximum Evapotranspiration Extinction Depths

Land Cover Type	Initial Value [m]	Minimum Value [m]	Maximum Value [m]
Natural (uncleared) areas	5	1	20
Swamp and alluvial	2	0.5	5
Pasture / grassland	1	0.5	2
Bare ground (open mine pit)	1	0.5	2

Within the historical Alcoa coal mine void, the evapotranspiration surface is changed over time according to the area of open cut mine developed at any given time. It is assumed in these areas that the evapotranspiration surface is the same as the Drain boundary elevations, which can change during history matching (see Section 4.5.9). When (if) these open cut areas are subsequently backfilled, the evapotranspiration surface is set at the pit floor elevation as recorded in the 2021 project DEM, which reflects rehabilitated mine pit conditions.

An attempt was made to make the EVT surface adjustable during history matching; however, this was found to instil too much instability in the models, and therefore adversely affected the model history matching and uncertainty analysis processes. It was therefore abandoned.

The sensitivity of groundwater evapotranspiration rates to projected future climate changes will be assessed using the PERFECT model climate scenarios described in Section 4.5.6. To be clear, PE-AE from versions of the PERFECT models with altered rates of potential evaporation will be used to define maximum evapotranspiration rates in MODFLOW-USG's EVT package in each climate scenario, just as they are for the history-matching models.

4.5.8 Creeks and Rivers

MODFLOW-USG's Streamflow Routing (SFR2) package is used to simulate stream flows through the modelled catchment (Figure 4-9), and stream interaction with groundwater. This package accumulates and routes applied quickflow (Section 4.5.5) and baseflows from headwaters down the length of each stream. With MODFLOW-USG's upstream weighting option invoked, this package can pass leakage from the stream down to underlying partially- or fully saturated layers via completely unsaturated ("dry") layers; this may be important for the Anglesea model but was not available in most older versions of MODFLOW. This functionality holds true for any applied flux and/or boundary condition in MODFLOW-USG when the upstream weighting option is used.

The package as applied here uses Manning's equation to simulate time-varying stream stage in response to variable flow routing volumes; Manning's n is set to a value of 0.1, which is not adjusted during history-matching. A simple rectangular channel cross section is applied, with widths as defined in Table 4-3. The location of all SFR nodes in the model is presented in Figure 4-9.

Streambed hydraulic conductivity, which controls the degree of channel leakage to and/or from the groundwater system, is made adjustable for model history-matching. This is implemented using pilot points and kriging (via PLPROC's calc_kriging_factors_auto_2d function; see Doherty, 2016c and Doherty, 2003). This is initially set to 0.1 m/day, based on initial manual history-matching. The optimised base realisation of optimised bed hydraulic conductivity and the range of optimised uncertainty is discussed and shown later in this report, in Section 6.1.7 and Figure 6-34.

Table 4-3 Modelled Initial Stream Properties

Strahler Stream Order	Stream Base Width (m)	Stream Bed Thickness (m)	Manning's n (/m)
1	0.5	1	0.1
2	0.5	1	0.1
3	2.5	1	0.1
4	5	1	0.1

Some of the outputs from PERFECT are used to define inputs to the MODFLOW-USG groundwater model. Quickflow (runoff plus interflow) estimated by PERFECT (see Section 4.5.5) is directly passed, with adjustable time lag factors (see below), to the downslope receiving Streamflow Routing (SFR2) package reach of the MODFLOW-USG groundwater model. This depends on the proportional area of soil type and land use (i.e., PERFECT model polygons; see Section 4.5.5) within the contributing watershed area for each SFR2 reach and is implemented using a Python script. Note that SFR2 reaches are shown as model cells in Figure 4-9 – so there are many small watersheds within which PERFECT's quickflow estimates are accumulated for.

Daily runoff and interflow estimated by the PERFECT models is delayed using simple linear decay stores with daily release factors that are made adjustable during model history matching. These stores work by releasing only a defined fraction of the runoff and interflow from PERFECT to the SFR2 network per day; the residual is accumulated over into the next day, when the same fraction of the residual, plus additional runoff, and interflow from that day, is released to the SFR2 network. Initial runoff decay is 0.95, and that for interflow is 0.9, for all PERFECT models, however these can differ from one another during history matching.

Spatial scaling of applied interflow is implemented at the groundwater model cell scale as is described for recharge in Section 4.5.5, but this is not applied to runoff given the poor regression quality between rainfall and runoff variability (see the second figure in Appendix A). Cell-scale spatial variability[14] in applied runoff and interflow from PERFECT is implemented using pilot points as was described for recharge in Section 4.5.5; these are scaling parameters with an initial value of 1, and are adjusted during history matching and uncertainty analyses, as informed (or not) by the observation data.

For the initial steady state model, PERFECT's estimate of average inflows to the stream network over the same period as that used to define steady state recharge is applied (1960 through 2021; Section 4.5.5).

[14] I.e., beyond the variability represented by the 237 land cover / soil type / climate gauge (PERFECT model) polygons.

MODFLOW USG's GAGE package is used to record modelled flow timeseries at the SFR2 reach locations of flow gauges for history-matching (see Section 5).

During model design, consideration was given to the need to simulate drying and rewetting of model cells beneath modelled streams; in earlier versions of MODFLOW, if a cell beneath a stream became desaturated (because of low rainfall and/or other factors), then the modelled stream flowing over the top of the cell would (unrealistically) stop interacting with the underlying groundwater. The software used for this model, USG-Transport, caters for such situations if upstream-weighting and Newton-Raphson iterations are activated - which they are - by never removing dry model cells from the groundwater flow equations. That is, in this model, streams can always lose water to underlying desaturated aquifers, which is potentially an important requirement in the modelled Anglesea catchments.

Related to this question, consideration was also given to model capability in simulating delayed leakage from streams to the watertable via the vadose zone, given the potential for very deep watertable levels around the Alcoa mine void and lower Anglesea and Salt Creek swamplands. Whilst MODFLOW-USG can simulate such vadose zone processes beneath losing streams, it is considered an unnecessary complexity, and best practice modelling suggests that complexity should be avoided unless that complexity is of direct relevance to required model forecasts (Doherty and Moore, 2021).

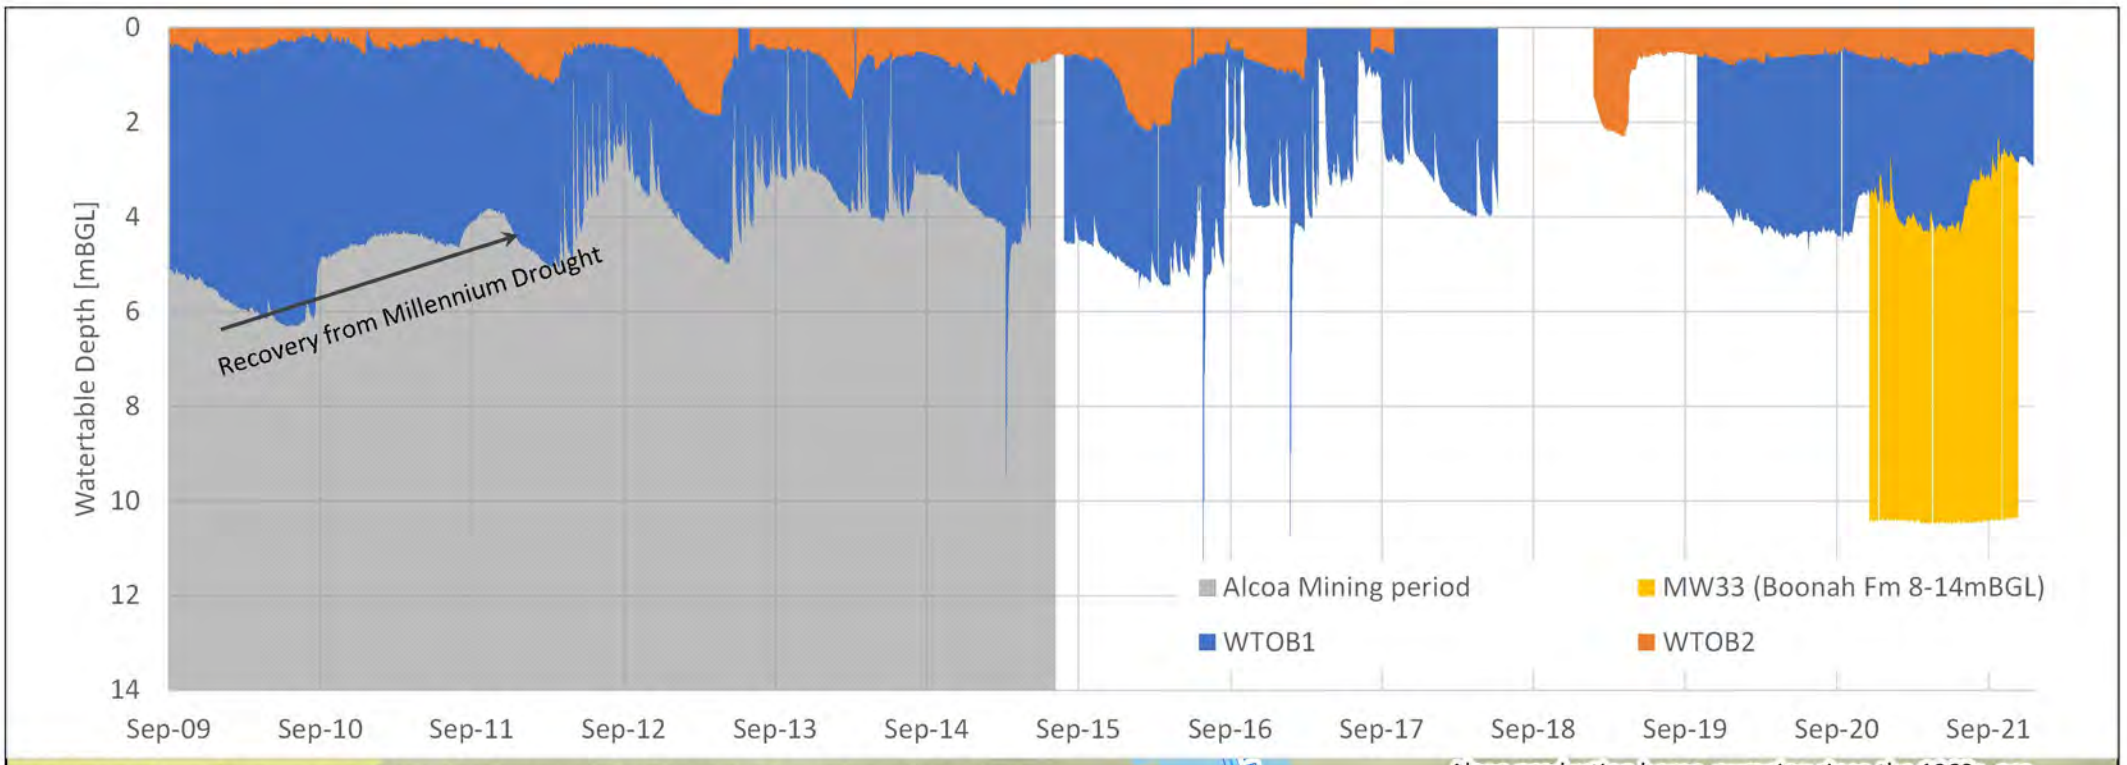
Figure 4-13 presents a series of observations relating to the issue. In summary, there is no evidence of a very deep watertable in the swamps and/or other sediments underlying the lower Anglesea River and/or Salt Creek. To the contrary, the watertable is observed to be consistently shallow (typically less than 5-10 m) throughout this area, with no evidence that historical mine pit dewatering and/or UEVF groundwater pumping has desaturated the shallow watertable around the Alcoa mine; of course, immediately adjacent the pit, this is unlikely to hold true, but from the evidence presented, it appears that any desaturation must only exist within very close proximity to the pit. This is consistent with the conceptualisation of the swamp groundwater system as presented by GHD (2013) and is the reason why the swamp/alluvial watertable aquifer was originally named the "Perched Watertable" (PWT) by GHD (2013)[15]. This is also consistent with the clear long-term evidence of the extensive swamplands remaining swamplands, with periodically groundwater-dependent vegetation, despite Alcoa mine void development since the 1970s, and despite the Millennium Drought.

However, it is important to understand that this is not to say that deeper sediments (e.g., UEVF sub-units) *underlying shallow saturated sediments* (i.e., the ASA) in the lower catchment area are not or have not ever become desaturated in response to mine void development and/or groundwater abstraction. To the contrary, the observation data suggests that this is a near certainty in some places, *must* be true in the immediate vicinity of the (dewatered) pit, and may also have occurred naturally in places in the pre-mining period. This is also consistent with the conceptualisation of GHD (2013).

Based on the available evidence, there is no need to introduce the added unnecessary complexity to the model to simulate delayed and attenuated leakage from streams to the watertable around the Alcoa mine void in the lower catchment, because the watertable in this area beneath streams is typically within 5-10 m of land surface, if not shallower. MODFLOW-USG's SFR2 package in its basic form as used here operates under the same assumption as similar head-dependent boundary conditions such as the River package; that is, "*that flow across the streambed sediments is translated directly to the water table without delay, and that the leakage rate does not exceed the saturated hydraulic conductivity of the deposits or rocks that occupy the interval between the bottom of the streambed sediments and water table*" (see Langevin and others, 2021). Given the observed shallow watertable beneath streams and the relatively coarse temporal model discretisation, this is considered a reasonable simplifying assumption for the Anglesea groundwater model.

The sensitivity of groundwater runoff and interflow rates to projected future climate changes will be assessed using the PERFECT model climate scenarios described in Section 4.5.6.

[15] Since renamed to the Alluvial / Swamp Aquifer (ASA)



Historical observed swamp watertable depths around the Alcoa mine have always been shallow (typically less than 5 m below ground). Bores WTOB1 and WTOB2, located 400 and 600m from the mine void, provide evidence of this (above). This holds true over the relatively dry period from 2009 until August 2016 when Alcoa ceased groundwater pumping and pit sump dewatering. The early part of the active mine operations period shown above was also recovering from the extremely dry period of the Millennium Drought.

On this basis, there is no need to simulate delayed leakage from streams to the watertable via the vadose zone in these areas, because the watertable is and always has been consistently shallow in the available historical record.

Further evidence of this is the fact that the Anglesea and Salt Creek swamps remain and have always been swamps - i.e., areas of shallow watertable with periodically groundwater-dependent vegetation.

There is no evidence of swamp watertable desaturation in response to mine void dewatering that has occurred since the 1970s within 1km of bore WTOB1. The deepest, most recent area of mine void development is 500m from WTOB1, yet the observed data show no desaturation. The watertable has always been within 6m depth from ground surface.

Alcoa production bores, pumping since the 1960s, are located 500m south of WTOB2. The current production bore being used for the 12-month pumping test is also in this area. To date, there is no evidence of desaturation impacts in the swamp watertable at this bore. Nor is there evidence of watertable desaturation from mine void dewatering that has occurred since the 1970s within 1km of bore WTOB2.

Shallow Alcoa bores in this area also exhibit shallow perched watertable within the shallow DBF. Shallow water levels in this area are known to be contributed to by leakage from the Alcoa ash ponds and potentially mains leakage (EHS, 2021).

Watertable depths increasingly likely to be shallow closer to Anglesea Estuary and the coastal boundary.

Alcoa bore MW33 in this area, screening the Boonah Fm from 8-14m below ground, indicates a watertable depth of around 10m below ground over the bore's life from 2020-present. This is showing a rising trend since July 2021, despite the ongoing UEVF pumping test.

4.5.9 Alcoa Coal Mine, Sump, and Rehabilitated Pit Water Body

The Mining Period

Historical mine drainage from groundwater into the mine sump is simulated using MODFLOW USG's Drain (DRN) boundary[16]. Drains are located across the actively mined pit floor locations, which vary over time according to information provided by Alcoa. Drain elevation is initially assigned using a single mine floor elevation estimate for each major mining block within the mined area, as provided by Alcoa. However, the elevations and therefore layers intersected by the Drain boundaries are allowed to vary at a finer spatial scale than the mining block during model history-matching - by +/-10 m from Alcoa's block-based estimates. This is achieved using pilot points scattered throughout the historically mined area.

Drain conductance is initially defined using:

- The vertical permeability of the model layer that each Drain boundary cell intersects (as defined by its elevation),
- Intersected cell areas, and
- An assumed clogging layer thickness of 1 m.

Conductance is however adjusted during history-matching as a factor of the initial estimate, as informed by recorded mine sump pumping rates, noting that sump pumping includes runoff into the mine void, and Alcoa has historically estimated the proportion of runoff versus groundwater at certain times; uncertainty arising from this is accounted for through the inclusion of significant error (noise) on these observations as described in Section 5.2, and relatively little weight should be placed on them in the history-matching process. Optimised Drain conductance values for the base model realisation are presented in Figure 4-14.

Evapotranspiration of shallow groundwater from the historical mine pit floor is simulated using the EVT package as is described in Section 4.5.7.

Drain boundaries are also applied to layers overlying the mined seam; DRN elevations for these are set to the cell floor elevation, and conductance is calculated in the same way as the mined layer but using the respective layers' hydraulic conductivity. In practice, these overlying DRN cells represent removal of water from storage as overburden is removed from the excavated pit. As time progresses, flux into these layers will comprise lateral and vertical inflow to the pit sides and floor (seepage), much of which is likely to evaporate on the pit walls and floor before reaching the sump; over the entire historically mined area (1.68 km^2), evaporation could range from approximately 3.5 to 4.8 ML/day, for an average annual evaporation rate of 1050 mm/year.

At the times and locations of mining initiation, aquifer properties are altered to reflect their (subsequently) backfilled and/or mining-modified hydraulic properties (vertical and horizontal hydraulic conductivity, specific yield, and specific storage). This is achieved using USG-Transport's Time-Varying Materials (TVM2) package (Panday, 2023). Note that the Drain conductance calculations described above are however made using "host" (pre-TVM application, or pre-mining) properties. Initial TVM properties for each layer are provided in Table 4-4; in practice during history matching, these values are variably changed at a fine spatial scale using pilot points. Some areas of the pit were never backfilled, and they remain open void; these areas are still assigned the TVM properties outlined in Table 4-4, however, they generally do not ultimately affect the simulation, because the Lake (LAK) package inactivates these model cells in the post-mining period in terms of groundwater flow, instead simulating the pit water body here as a time-varying head boundary based on the pit water balance (see discussion below) [17]. Maps showing the optimised base model realisation hydraulic properties for the mined area are presented in Figure 4-15 through Figure 4-18.

[16] Although it would be possible to simulate the historical mine pit using the LAK3 package, this was considered unnecessarily complicated and prone to significant data limitations. We instead chose to focus history matching of water body behaviour and LAK3 package parameters on the post-mining (rehabilitation) period, given that this relates to many key model forecasts of interest (see Section 2.1), and is the period over which we have more robust data with which to constrain water body hydrology.

[17] In places, they may affect LAK-groundwater conductance values in the post-mining period.

Table 4-4 Simulated Alcoa Mine Excavation and Backfill Properties

Model Layer	Kh [m/day]	Kv [factor of Kh; -]	Ss [/m]	Sy [-]
1	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]
2	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]
3	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]
4	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]
5	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]
6	10 [0.001 - 30]	1 [0.001 - 1]	0.0001 [0.000001 - 0.001]	0.2 [0.01 - 0.5]

Note: Values show are the initial value used in history matching, with the allowable range shown in brackets.

The Post-Mining Period

MODFLOW USG's Lake package (LAK3; Merritt and Konikow (2000); Panday and others (2013)) is used to dynamically simulate Alcoa's rehabilitated pit water body water balance and hydraulics, in response to underlying and surrounding groundwater pressures and aquifer properties. It is shown in Figure 4-9.

In the simulated post-mining period, the LAK3 package is assigned to model layers 2, 3, 4 and 5 (DBF through to the UEVF Upper Sands), as dictated by pit floor geometry (bathymetry) and history matching. The top of layer 2 within the water body is set to 7 mAHD – the maximum achievable final pit water body level given current spill levels. The Lake package as applied here uses specified water body (pit) bathymetry within mined areas; this defines modelled water body level- volume and area curves. Bathymetry is defined using a combination of the 2021 and 2017[18] project DEM elevation data sets.

For wetted water body areas, groundwater flow is internally deactivated by MODFLOW-USG, as is the EVT package (evapotranspiration from shallow groundwater) and recharge (RCH) package. When these areas of water body bed dry out, applied recharge and groundwater evapotranspiration are reactivated and applied to the cell underlying the water body bed. The maximum extent of the modelled water body boundary is shown in Figure 4-9.

- Modelled water inflows to the pit water body boundary condition include the following:
    - Upward seepage from groundwater through the water body bed.
    - Runoff and interflow from the local pit catchment, as estimated using the project Digital Elevation Model (DEM) and recently installed surface drain information (EHS, 2022a).
    - Direct rainfall.
    - Artificial augmentation, for example as occurred during Alcoa's 6-month UEVF pumping trial in 2021.
- Pit water body outflows include:
    - Evaporation from the water body water surface. This will increase with increasing pit water body surface area (I.e., as the pit water body level rises).
    - Potential leakage to groundwater at times.
    - (Potentially) water body spill outflow to the Anglesea River.

Runoff and interflow components are defined using the outputs of the recharge-runoff model as is described for SFR2 reaches in Section 4.5.8. Potential water body evaporation rates are derived from the evaporation gauge closest to the mine (Anglesea). An initial pit water body pan evaporation factor of 0.75 was applied based on EHS (2022a) but is made adjustable during history matching. Allowable ranges for history matching consider alternative estimates including those using Morton's water body evaporation, which is included with SILO.

The sensitivity of groundwater runoff and interflow rates to projected future climate changes will be assessed using the PERFECT model climate scenarios described in Section 4.5.6.

Initial water body bed leakance values were defined using the vertical hydraulic conductivity values of the underlying groundwater model cell for both horizontal and vertical connections, because in practice modelled horizontal connections from the lake to surrounding groundwater are sub-vertical. This is adjusted during history matching, as the properties of the water body bed material can only be inferred through the observed groundwater and water body level data.

The sensitivity of groundwater runoff and interflow rates to projected future climate changes will be assessed using the PERFECT model climate scenarios described in Section 4.5.6. Potential pit water body evaporation rates will be scaled accordingly.

[18] The 2017 DEM is used where the 2021 DEM represents the submerged pit water body area.

4.5.10 Groundwater Abstraction

All groundwater users' bores were simulated using MODFLOW USG's Well (WEL) package (Panday and others, 2013). These bores are presented in Figure 4-9. For all Alcoa and Barwon Water production bores, these WEL boundaries are simulated within MODFLOW-USG Connected Linear Networks (CLNs). The CLN package allows a bore to pump from more than one screened aquifer, which was historically the case in at least one Alcoa production bore. It also simulates head and storage within the bore itself, as affected by well losses and the conductance between the bore and the aquifer.

Bore construction details are used to define the radius and length terms CLN package where available, and the Thiem equation with no skin is used to estimate CLN to groundwater cell conductance.

Actual groundwater abstraction data are available for the Alcoa power station extraction boreholes for the period April 1970 to 2022 and these data are used to calculate average monthly rates for each of the bores. All recorded historical groundwater abstraction data are presented in Appendix B. It is worth noting that the Alcoa bores were often historically used on a sub-daily (on/off) basis, and that recorded production bore groundwater levels comprise a mix of static (no pumping) and pumped levels. This means that when fine temporal scale historical pumping data are aggregated up to coarser model stress periods (often monthly or longer), there is often a conflict between model temporal resolution, the resolution at which observed production bore groundwater levels are recorded, depending on whether those bores were actively pumped at the time of each groundwater level record. This conflict is considered in design of the model history matching process in terms of groundwater level data from intermittently pumped production bores (see Section 5.2.1).

Also of note for the Alcoa production bores is that the construction details of some are not well known. At least one is known to have screened both the LEVF and UEVF aquifers (WB9), whilst others are thought to *possibly* screen both aquifers (WB10 and WB4). Other factors that are known to affect a bore's connection to the screened sub-strata are screen and bore integrity. In recognition of these uncertainties, adjustable model parameters are introduced to the history matching process that allow a fraction of the initial (best guess) screened LEVF length to be reassigned to the bore's (CLN) connection to the UEVF aquifer. Initial LEVF screen length factors for these three bores are 0.9, based on initial manual history matching efforts and available data along with the geological model; allowable ranges are 0.001 to 0.98. Optimised LEVF screen length factors for WB10, WB9 and WB4 are 0.69, 0.34 and 0.16, respectively.

Furthermore, several of the Alcoa production bores that may intersect multiple aquifers have been decommissioned in recent years; this cessation of potential inter-aquifer connection via the bore is simulated in the model using USG-Transport's Transient Ibound (TIB) package (Panday, 2023). Using the same package, these bores' time of construction is used to define the stress period in which each bore (and the associated potential aquifer inter-connectivity) is activated in the model.

No actual abstraction data are available for the Moriac Quarry or the other agricultural and domestic groundwater users and hence steady extraction at licensed quantities or 2 ML/year for stock and domestic bores are assumed.

Current licensed extraction from the LEVF is limited to around 0.7 ML/day in total from the Moriac Quarry and one minor agricultural abstractor. Total licensed abstraction from the UEVF totals approximately 11.9 ML/day pre-Alcoa mine closure. Modelled abstraction locations are shown in Figure 4-9, and summarised in Table 4-5. There are estimated to be approximately 53 stock and domestic bore users within the model domain, most of which are (or were) located near Jan Juc and Torquay in the east. These bores largely extract from the Torquay Group (model layer 2).

Table 4-5 Modelled Long-Term Average Groundwater Abstraction Rates during Historical Operational Periods

Bore	Modelled Layer
Barwon Water ASR	Upper Eastern View (Layer 7)
Barwon Water GW1	Lower Eastern View (Layer 11)
Barwon Water GW2	Lower Eastern View (Layer 11)
Barwon Water GW3	Lower Eastern View (Layer 11)
Barwon Water GW4	Lower Eastern View (Layer 11)
Barwon Water GW5	Lower Eastern View (Layer 11)
Barwon Water GW6	Lower Eastern View (Layer 11)
Barwon Water GW7	Lower Eastern View (Layer 11)
Alcoa WB10	Upper & Lower Eastern View (Layer 7, 11)
Alcoa WB12	Upper Eastern View (Layer 7)
Alcoa WB13	Upper Eastern View (Layer 7)
Alcoa WB14	Upper Eastern View (Layer 7)
Alcoa WB15	Upper Eastern View (Layer 7)
Alcoa WB16	Upper Eastern View (Layer 7)
Alcoa WB17	Upper & Lower Eastern View (Layer 7, 11)
Alcoa WB4	Upper & Lower Eastern View (Layer 7, 11)
Alcoa WB5	Upper Eastern View (Layer 7)
Alcoa WB9	Upper / Lower Eastern View (Layer 7 / 11)
Moriac Quarry	Lower Eastern View (Layer 11)
Buchanan Irrigation Bore	Lower Eastern View (Layer 11)
Stock and domestic users	Primarily Torquay Group (Layer 2) and other shallow formations

4.6 Hydraulic Properties

MODFLOW-USG's Layer Property Flow (LPF) package is used with upstream weighting (layer type 4) for calculating groundwater flow components in the model. This requires definition of aquifer hydraulic properties, parameterisation of which is now outlined.

Table 4-6 presents initial (pre-history-matching, or "prior") horizontal and vertical hydraulic conductivity parameters, and their allowable upper and lower bounds for history-matching. Table 4-7 presents the same information, but for aquifer storage parameters.

These are presented for each model layer (which are described in Table 4-1) and are based on field data from Alcoa and Barwon Water where available, and/or the available literature (primarily Rau and others (2018), and Chowdhury and others (2020)), along with the application of conceptual judgement and experience. It is important to note that these parameters are for input to the numerical model's history-matching process; there are therefore several points of important note regarding their definition and use in the modelling context:

- Initial values and allowable ranges need to reflect what each model layer represents in reality - i.e., highly variable lithologic units - versus its simplified, discretised form (a single model layer, with each model cell representing variable-sized portions of that highly variable geological material).
- Allowable ranges need to be wider than field test data might indicate. This is because of the variable materials that each model cell represents, and because field test data is subject to bias. Both observation and production bores tend to be screened in the most permeable (highest yielding) portions of aquifer material. Furthermore, several bores screened within the same model layer will often likely screen different sub-units within that layer; this is likely to be a major contributor to model structural noise in this model. Bores are also only sparsely located across the model domain, relative to the scale of true geological variability.

Figure 4-19 through Figure 4-23 present maps of modelled horizontal hydraulic conductivity, for the history-matched "base" realisation[19]. The prior realisation is not presented here because there is little spatial variability, so little of interest to display; local prior variability is only present at the Barwon Water and Alcoa production bores, primarily within the UEVF and LEVF aquifers.

Figure 4-19 through Figure 4-23 show the "pilot point" parameters (red dots; see Doherty (2003)) that are used to introduce spatial aquifer parameter variability to model parameters for each layer. Interpolation from these pilot point parameter locations to the model mesh is undertaken for each layer and parameter type using kriging, via PLPROC's calc_kriging_factors_auto_2d function (see Doherty, 2016c). Kriging ranges are defined using MKPPSTAT (Doherty, 2016d), with ranges defined as twice the average distance from each pilot point to its closest eight neighbouring pilot points, in the same layer. Kriging sills are defined as one; all parameters are log-transformed, so this equates to one order of magnitude sill variability at and beyond the (spatially-variable) range distance. No kriging anisotropy is implemented.

Horizontal and vertical hydraulic conductivity (its ratio to hk), specific storage, and specific yield were all parameterised in this way. Specific yield parameters in areas that never become unconfined (offshore) are not adjusted during history matching. Maps of optimised base realisation parameter sets for vertical hydraulic conductivity are presented in Figure 4-24 through Figure 4-28. Corresponding maps for specific storage are presented in Figure 4-29 through Figure 4-32, and for specific yield in Figure 4-33 through Figure 4-37. Parameter range reductions from the prior (pre-history matching) realisations to those of the posterior are discussed and presented in Section 6.1.7.

The same set of pilot points are used for all layers but are limited to the spatial extent of each active model layer area, as shown in Figure 4-19 through Figure 4-37. Pilot point locations were defined using a combination of the following:

- A selection of regularly spaced SFR package nodes, and the ASA extent polygon, to ensure spatial parameter flexibility in the important stream valley floors.
- A custom Python script to build regularly spaced and aligned point data sets along and within the Jan Juc anticline, to allow flexibility in hydraulic connectivity (or lack thereof) across the anticline within the LEVF (see the area of low hydraulic conductivity across the anticline in Figure 4-23, which is not present in the other layers, because those layers are known to be thick and continuous over the anticline).
- Production and observation bore locations – to encourage a variable density of pilot points (and spatial variability) depending on observation and production bore density in different areas of the model.
- The historical Alcoa coal mine polygon – to ensure sufficient pilot points in and around this important feature.
- Triangulation within the domain using Algomesh (HydroAlgorithmics, 2020), using the input points and polygons defined above. It can be seen in Figure 4-19 through Figure 4-23 that there is reduced pilot point density further from areas of interest, aquifer stress, and monitoring; for example offshore and to the east.

[19] The "base" realisation in PESTPP parlance is the model parameter realisation (one of many) that is either the history-matched (posterior) parameter set derived from the initial (prior, expert knowledge-based) parameter set, or the prior itself. In this case, all other model realisations are centred around the base realisation, for both prior (un-optimised), and posterior (optimised / history-matched) realisations.

Table 4-6 Initial modelled aquifer hydraulic conductivity parameter values and allowable ranges per model layer

Parameter	Layer	Initial Value	Min Value	Max Value	Initial Value Basis
Horizontal Hydraulic Conductivity (hk) [m/day]	1	1.08E+00	8.64E-05	3.00E+01	Chowdhury et al (2021) sandy material, limited maximum to 30m/day. Min reduced to account for stratigraphic variability.
	2	4.06E-03	1.73E-05	3.02E+00	Chowdhury et al (2021) clayey material. Min reduced to account for stratigraphic variability.
	3	4.32E+00	8.64E-05	5.00E+01	Chowdhury et al (2021) sandy material. Min reduced to account for stratigraphic variability.
	4	1.00E-01	8.29E-04	1.21E+01	No coal data, so author experience from pumping and drill stem tests in coals in the Surat Basin, which range from 1e-4 to 1E+1, median ~1E-1 (noting they are probably more competent, more deeply buried coals than those at Anglesea)
	5	1.47E+00	8.64E-05	5.00E+01	Average of pumping test mean and min for initial value - to account for pumping bores targeting most productive strata. Max loosely based on UEVF test data. Min from Chowdhury et al (2021), but reduced to allow for stratigraphic variability.
	6	4.92E-01	8.29E-04	3.00E+01	Chowdhury et al (2021) silty material (no tests on this less permeable UEVF unit). Min reduced to account for stratigraphic variability. Max based loosely on UEVF test data. Min reduced to account for stratigraphic variability.
	7	1.47E+00	8.64E-05	7.50E+01	Average of pumping test mean and min for initial value - to account for pumping bores targeting most productive strata. Max based on UEVF test data. Min reduced to account for stratigraphic variability.2
	8	4.06E-03	1.73E-05	3.02E-02	Chowdhury et al (2021) clayey material. Min reduced to account for stratigraphic variability.
	9				
	10				
	11	8.90E-01	8.64E-05	5.00E+01	Average of pumping test mean and min for initial value - to account for pumping bores targeting most productive strata. Min from Chowdhury et al (2021), but reduced to account for stratigraphic variability. Max also from Chowdhury but limited based on LEVF and UEVF test data.
	12	7.17E-02	1.04E-05	3.00E+01	Chowdhury et al (2021) sandstone. Min increased by two orders of magnitude, based on shallow fractured aquifer at Anglesea. Max limited based on conceptual understanding.
Vertical Hydraulic Conductivity Factor of hk (kzf) [-]	1	1.00E-03	1.00E-04	1.00E+00	Assumed; no data. But given this is a thin discrete alluvial/swamp peat unit, this seems conceptually reasonable.
	2	2.45E-03	2.50E-05	1.00E+00	Ratio of test data geomean kv to mean hk for initial value. Min value 50% of UEVF test min. Max assumed.
	3	1.00E-03	1.00E-05	1.00E+00	Assumed; no data. But given this is a thin discrete sand unit, this seems conceptually reasonable.
	4	9.27E-04	1.00E-05	1.00E+00	Assume cleats are sub-vertical so not a lot of h-->v contrast
	5	9.27E-03	1.00E-05	1.00E+00	Average of UEVF tests. Min value 20% of UEVF test min. Max assumed.
	6	9.27E-03	1.00E-05	1.00E+00	Average of UEVF tests. Min value 20% of UEVF test min. Max assumed.
	7	9.27E-02	1.00E-05	1.00E+00	Average of UEVF tests. Min value 20% of UEVF test min. Max assumed.
	8	1.00E-01	2.50E-05	2.00E+00	Assumed, no tests, but 1E-1 gives slightly lower than UEVF kv, which seems reasonable conceptually for this

Parameter	Layer	Initial Value	Min Value	Max Value	Initial Value Basis
	9				primary regional aquitard unit. Min value 50% of UEVF test min. Max assumed; allowed higher than kh to allow for potential cracks, discontinuous clay sub-units and exploration drillhole pathways.
	10				
	11	9.27E-04	1.00E-05	1.00E+00	Average of UEVF tests. Min value 20% of UEVF test min. Max assumed.
	12	1.00E-01	1.00E-05	1.00E+00	Assumed, no data

Table 4-7 Initial modelled aquifer storage parameter values and allowable ranges per model layer

Parameter	Layer	Initial Value	Min Value	Max Value	Basis
Specific Storage [/m]	1	1.20E-05	2.30E-07	2.00E-03	N/A - unconfined aquifer
	2	1.73E-06	2.30E-07	8.00E-04	DBF - assume Rau et al (2018) geomean and range from Chowdhury et al (2021).
	3	4.74E-06	2.30E-07	2.00E-03	Boonah Fm - assume similar to UEVF (so Rau et al (2018) geomean of mid-upper, and range from Chowdhury et al (2021))
	4	1.00E-05	2.30E-07	1.00E-03	Largely coal - assume higher storage
	5	4.74E-06	2.30E-07	2.00E-03	UEVF Rau et al (2018) geomean of mid-upper, and range from Chowdhury et al (2021).
	6	4.74E-06	2.30E-07	1.00E-03	UEVF Rau et al (2018) geomean of mid-upper, and range from Chowdhury et al (2021).
	7	4.74E-06	2.30E-07	2.00E-03	UEVF Rau et al (2018) geomean of mid-upper, and range from Chowdhury et al (2021).
	8	1.73E-06	2.30E-07	8.00E-04	MEVF - assume Rau at al (2018) geomean, and range from Chowdhury et al (2021).
	9				
	10				
	11	3.02E-06	2.30E-07	2.00E-03	LEVF - geomean test data mean and min --> assume that the pumping test derived values are overestimates for models (which do not need an implicit leaky term). Chowdhury et al (2021) for range.
	12	3.70E-06	2.30E-07	4.00E-04	Chowdhury et al (2021) sandstone mean and range.
Specific Yield [-]	1	1.00E-01	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	2	1.00E-02	1.00E-03	5.00E-02	No data; Johnson (1967); calibratable
	3	1.00E-01	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	4	1.00E-02	1.00E-03	1.00E-01	No data; assumed based on the QLD UWIR model; calibratable
	5	5.00E-02	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	6	5.00E-02	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	7	5.00E-02	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	8	1.00E-02	1.00E-04	5.00E-02	No data; Johnson (1967); calibratable
	9				
	10				
	11	5.00E-02	5.00E-03	3.50E-01	No data; Johnson (1967); calibratable
	12	1.00E-02	1.00E-03	1.00E-01	No data; assumed, calibratable

5. Model History Matching - Design

5.1 Approach

This section details the philosophy behind the model history-matching (previously referred to as “calibration”) and uncertainty analysis approaches applied with the numerical groundwater flow model described in earlier sections of this report, aimed at meeting the model objectives and assessing the potential effects outlined in Section 2.1. This assessment of potential effects will subsequently be used to inform potential risks, water management-related decision-making, and regulatory processes relating to both Barwon Water and Alcoa operations.

In this study, “history-matching” refers to the process of assimilating observed groundwater and surface water systems’ data into the models. The purpose of history-matching in this context is to constrain model parameters and allowable ranges, based on what is known from field testing, conceptual ideas and observed system behaviour - ideally that of direct relevance to the model forecasts of interest.

This in turn constrains the suite of parameter sets that are used to make model forecasts and to assess their uncertainty (Figure 5-1 and Figure 5-2). Such an approach provides a good basis for enhanced use and understanding of model outputs, including their limitations, in model-dependent decision-making. It should be noted that the term “calibration”, as described in the Australian Groundwater Modelling Guidelines, is intentionally avoided in this report. The traditional approach of developing a single calibrated model can give a false expectation that there is a single deterministic set of best parameters. The approach adopted and described in this report derives a suite of plausible parameters that reflects the uncertain nature of the history-matching process, which can be extended to predictive uncertainty analysis in an efficient manner. This probabilistic approach has become more widely applied in groundwater modelling since the publication of the guidelines in 2012.

Mechanisms by which observation data are used in history-matching are outlined in Section 5.2. Parameterisation schemes and strategies are outlined in the Sections 4.6, 5.3, and 6.

PEST (Doherty, 2015 and 2016a), the software platform related to much of the work presented in this report, represents a family of code and workflows for highly parameterised environmental model optimisation (inversion), uncertainty analysis and associated tasks. In addition, a large set of support utilities have been developed, primarily by John Doherty of Watermark Numerical Computing.

A code that is derived from PEST is applied in the history-matching and uncertainty analysis processes applied in this study: PESTPP-IES, an Iterative Ensemble Smoother (IES; White, 2018). This code optimises an ensemble of random model parameter realisations on an iterative basis. It makes an estimate of the Jacobian (observation-to-parameter sensitivity) matrix, which is used by the traditional PEST code. It does this using the ensemble of parameters and observations, and the modelled equivalents thereof, for each parameter upgrade iteration.

These concepts comprise the applied workflows used in this study and are shown schematically in Figure 5-1. Along with the corresponding implementation detail in Figure 5-2; these figures cross-reference one another. Note that the history-matching process shown in the left side of Figure 5-2 is undertaken iteratively, with the “posterior parameter ensemble” arising from one iteration feeding back into the start of the next; the process is repeated until the level of history-match quality and the posterior parameter uncertainty range that is obtained is satisfactory (typically only a few iterations).

Key implementation details of PESTPP-IES’ application in this case are outlined in subsequent sections of this chapter. For further information, the reader is referred to the following key texts for a full description of the applied methods and theory underpinning this report:

- PEST – The Book (Doherty, 2015; particularly Section 4), and Chen and Oliver (2013) for the theory underpinning much of the inversion and uncertainty analysis of this report. Doherty (2015) and White, (2018) extend that theory to practical application in the environmental modelling and decision support context.
- The PEST, PEST++ and PESTPP-IES manuals and associated literature (Doherty, 2016a, 2016b; White., 2018, and PEST++ Development Team, 2023) for detailed information on practical application of the PEST and PESTPP-IES software, in addition to a range of analysis concepts, workflows and processes.

In terms of PESTPP-IES usage details, PESTPP-IES was instructed to centre its Jacobian estimates on the base (prior) parameter set, and automatic localisation was activated. Interested readers are referred to the PESTPP-IES manual (PEST++ Development Team, 2023).

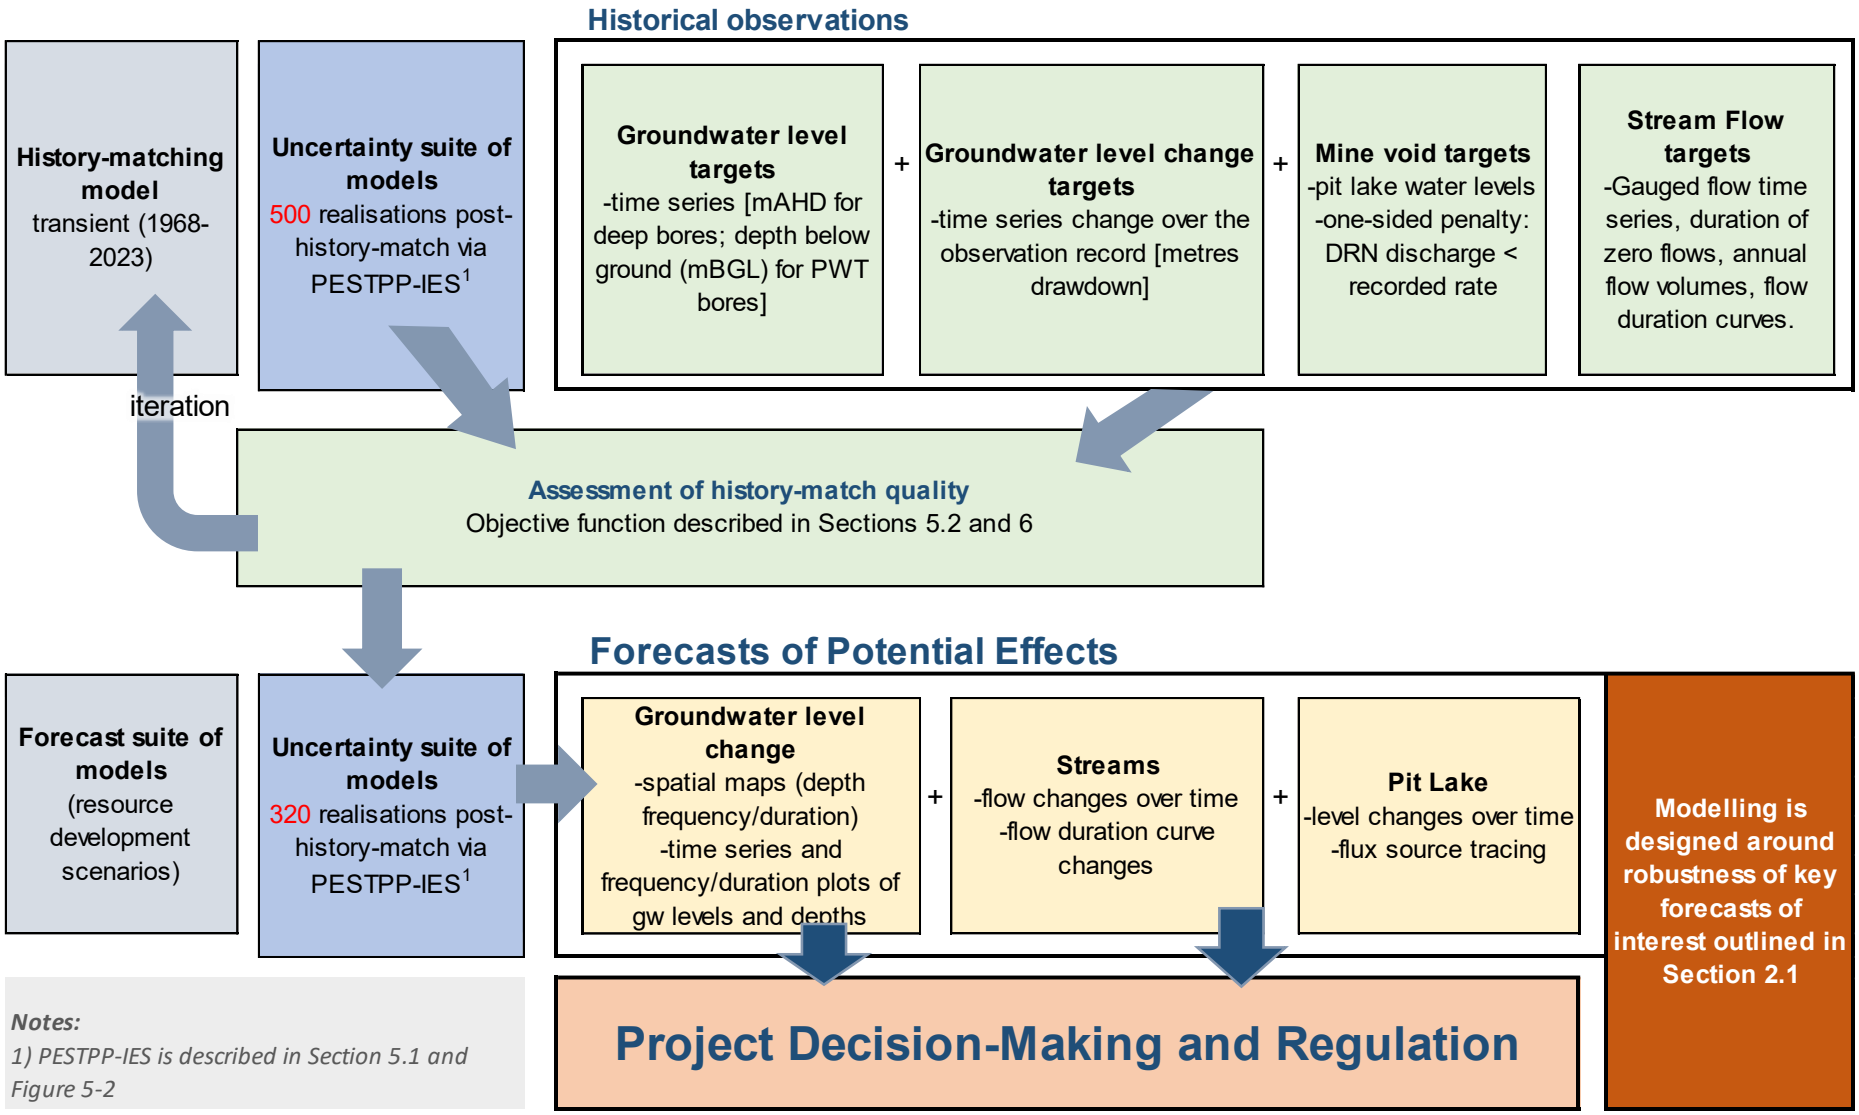

Figure 5-1 Schematic overview of the model history-match and uncertainty analysis workflows applied in this study.

PESTPP-IES estimates model parameter (and forecast) uncertainty using the principles of Bayes equation:
$P(k|h) = P(h|k)P(k)$

[A]	[B]	[C]	[D]	[E]
P(k) - Prior (pre-history-matching) probability distribution of model parameters ("prior parameter ensemble"). This is explained in Sections 4, 4.6, 5.1 and 5.3.	**P(h) - Prior (pre-history-matching) probability distribution of modelled equivalents to available observation data ("prior simulated observation ensemble"). In this case, noise is added to obs. based on estimated reliability.**	**P(h|k) - The likelihood of P(k) parameters, given the acceptability of the history-match between observation data and their modelled equivalents [P(h)], for each sample of P(k). This is explained in detail in 5 and 6.**	**P(k|h) - Posterior (post-history-matching) probability distribution of model parameters ("posterior parameter ensemble"). This is explained in detail in Sections 6.1.2 and 6.1.6.**	**P(s|h) - Posterior (post-history-matching) probability distribution of model forecasts given the posterior parameter probability distribution [P(k|h); see to left].**
				* PESTPP-IES takes semi-random samples of this, based on user-specified relevant parameter ranges, and any spatial or other parameter correlation (i.e. covariance). See Sections 4.6 and 5.3. * This collection of parameter samples is called the "prior parameter ensemble". The number of (user-specified) samples is called the "ensemble size". Each sample ("ensemble member") comprises one semi-random value for every model parameter, which are together used to parameterise a single model run.	* PESTPP-IES takes samples of this by running the user-specified number of samples of P(k) (i.e. the "prior parameter ensemble") parameters through the model. * Paired with this "simulated observation ensemble" is the equivalent "observation data ensemble" (i.e. what is used to assess the model history-match quality; see next column). * Uncertainty in the observation data ("noise") is added to each member of the observation ensemble, based on user-specified uncertainty ranges for each observation.	* Comparison of the observation data (plus noise) with their modelled equivalents [P(h)] is used to "filter out" parameters from P(k) for which the match between observations and their modelled equivalents (i.e., the "history-match") is of acceptable quality.	* This is the "filtered out" members of the prior parameter distribution [P(k)], which, when each member is run through the model, provides an acceptable level of history-match quality. * The posterior parameter distrbution from one PESTPP-IES iteration is fed back into the beginning of the next (as the prior parameter distribution).	* This is the "filtered out" members of the prior forecast distribution [P(s)] as derived by running each member of the posterior parameter ensemble [P(k|h); see to left] through the model. * As Doherty (2015) states: "*The extent to which the posterior predictive uncertainty of* ***s*** *is smaller than its prior predictive uncertainty is dependent on the information content of the data, the model parameters to which this information is pertinent, and the parameters to which* ***s*** *is most sensitive.* "
HISTORY-MATCHING (ITERATIVE)				**FORECASTING**

Figure 5-2 ***Schematic overview of implementation details for the model history-match and uncertainty analysis process applied in this study.***

5.2 Observation Data

PEST's role in model inversion is to minimise its objective function (phi) by adjusting model parameters in an iterative fashion (Doherty, 2015 and 2016a). Phi is calculated internally by PEST as the sum of squared weighted residuals between observations and their modelled counterparts. Observations used in this case are outlined in Table 5-1 and Table 5-2, and their locations are shown in Figure 5-3. PEST allows the user to group different observation data types and weight these groups (and individual observations within each group) differently. This allows the modeller to strategically (and subjectively) weight different observation types and locations according to the objectives of the modelling.

There are a whole host of reasons for weighting different data points differently, which will not be discussed in detail here; the interested reader is referred to the PEST documentation referred to earlier. To provide an example, strategic weighting may be used to account for the fact that some bores or flow gauges can have far more data than others; those with fewer observation data may be less "visible" to PEST during inversion, unless their weighting is increased relative to those sites with more data. Other reasons for different weightings may include less reliable versus more reliable data. Or maybe that bores in a particular area are more important to the project objectives than those in other areas.

In this case where PESTPP-IES is used, noise (an estimate of observation data error, including structural model error), can also be optionally added to the observation data realisations. This is implemented with the estimates of error outlined in Table 5-3. These noise estimates define the accuracy to which the model can be reasonably expected to simulate each measurement used in the history-matching, given all its assumptions and limitations. The applied noise is not just a reflection of survey error - it is in large part driven by structural model limitations and assumptions. The application of noise in this way minimises undue model parameter bias incurred through history matching, which can and often does have ramifications for model predictive bias. See White (2018) and PEST++ Development Team (2023) for further detail.

5.2.1 Implementation details

Details of the workflow and underlying utilities used to implement each observation type are presented in Figure 5-4.

All groundwater level, pit water body level, sump discharge, and flow observation data are resampled (averaged) to a single observation per model stress period; this process was used to iteratively refine model stress period discretisation, ultimately leading to the stress period definition outlined in Section 4.3. Secondary data sets such as stream flow frequency-duration curves, groundwater depth-frequency-duration curves, and annual flow volumes, were derived from these resampled data sets to ensure that observations and their modelled counterparts are directly comparable for history-matching.

Groundwater level data from bores that were and/or are used as production bores are simulated using MODFLOW-USG's Connected Linear Network (CLN) package (see Section 4.5.10). Modelled groundwater levels at these bores therefore represent groundwater levels computed within bore casing at the sub-mesh (bore-) scale. Modelled groundwater levels at all other bores are simulated by MODFLOW's groundwater flow routines (within groundwater flow model or "GWF" cells) and are extracted from the model using PEST utility USGMOD2OBS (Doherty, 2016e), using distance-weighted averaging from the bore location to each of the neighbouring groundwater model cell centres.

Two other PEST utilities (described in Doherty, 2016d and 2016e) are also used for processing different observation data counterparts from the model: SMPDIFF, and USGBUD2SMP which are used to calculate changes in computed values and extract flow budget, respectively (customised for a slightly modified form of output).

All other observation processing tasks are carried out using custom Python[20] scripts, largely relying on the Flopy[21], Numpy[22], and Pandas[23] packages.

Table 5-1 Model History-Matching - Observation Data Summary

Type	Observation Groups	Count of Sites	Count of Observations	Description
Groundwater levels	-Bores <=30m depth -Bores >30m depth -Trigger bores (shallow and deep)	147	10,675 PEST observations (resampled from many more sub-stress period scale observations)	Groundwater levels as mAHD for deeper bores or mBGL for bores shallower than 30 m depth. Modelled depth below ground is calculated as the depth below the top surface of the model, whereas that at the bore is from the surveyed ground elevation at the bore. This aims to sidestep structural model error derived from discrepancies between topographic elevation at the model cell scale versus that at the bore scale.
Groundwater levels (dry bores)		7	196	Dry bores included as one-sided penalty functions in PEST; where modelled head is below the bore bottom elevation, the modelled value is set to that bottom elevation (which is also the observed value). In this way, the history match is only penalised when those bores are simulated as being at least partially saturated. These observations are defined from December 2021 onward, when these bores were installed.
Groundwater level differences	-Trigger bores -All other bores	48	1944	Vertical (inter-aquifer) head differences at nested sites (including VWPs). A 30 m distance (cluster) limit was applied to define nested sites. Also includes head differences between the pit water body and selected nearby bores.
Groundwater level change (drawdown)	-Trigger bores (shallow and deep) -All other bores (shallow and deep)	147	9362	Change in level since first recorded (and modelled) observation.
Stream flows	-Average rate within stress period -Annual flow volume	6	1073 (resampled to model stress periods), 97 annual volume observations.	
Interstation stream flow differences	Salt Creek (SV2/SV3), Anglesea River (AV1/AV2)	4	266	Downstream flow gain/loss between gauges.
Stream flow exceedance	No sub-groups	6	102	Flow duration curve statistics.
Zero stream flow	No sub-groups	6	300	

Type	Observation Groups	Count of Sites	Count of Observations	Description
Pit water body levels	No sub-groups	1	68	Pit water body water levels
Mine pit sump pumping	No sub-groups	1	108	Highly uncertain data due to (required) historical estimation of relative components of runoff, direct rainfall, and groundwater discharge into the sump.
WEL flow reduction penalties	No sub-groups	44	21,641	One-sided penalty observation for cases in which applied WEL boundary fluxes in any model are reduced due to (stochastic) parameters.
Mass balance error penalties	No sub-groups	1 (model-wide)	676	One-sided penalty observations of mass balance error per time step. Values exceeding 1% error incur penalties to PEST's objective function. This is implemented to enable forced convergence during automated history matching.

Table 5-2 Model History-Matching – Groundwater Level Observation Data Summary by Monitoring Unit

Monitoring Unit	Count of Bores	Count of Observations (pre-resampling to model stress periods)	Minimum Date	Maximum Date
(UEVF Intermediate Coal)	1	11456	22/07/2021	20/02/2023
ASA	12	54814	24/09/2009	03/03/2023
Boonah Formation	14	59990	01/11/2006	20/02/2023
DBF	17	496	01/06/1999	19/10/2020
DBF/BF	10	2253	01/11/2006	18/03/2021
LEVF	30	212043	31/12/1968	07/03/2023
Mine Overburden	1	16641	10/12/2020	20/02/2023

UEVF	35	289789	31/12/1968	03/03/2023
UEVF (Upper Sands)	7	110266	10/12/2020	20/02/2023
UEVF_LEVF	2	2586	18/03/1969	21/05/2018

Table 5-3 Applied Observation Data Noise

Observation Data Type	Observation Noise	Rationale
Groundwater level [mAHD / mBGL]	For deep bores: 1 m (mAHD) post-mining; 2m during mining, except for Alcoa production bores (10m); trigger bores: 0.25 m. For bores less than 30 m deep: 0.1 mBGL, except	Considering model cell resolution, elevation survey error, bore water level recording error.

Observation Data Type	Observation Noise	Rationale
	for Alcoa MW* bores (0.25 m).	
Groundwater level change [m]	Deep bores: 0.5m (during mining in southern syncline); 0.25m (post-mining and in northern syncline), 0.1m (trigger bores), 0.05 (shallow bores).	Change from one reading to the next should theoretically be more accurate than a single absolute reading. Cell resolution should be sufficient to overcome issues with bores being too close to one another.
Inter-aquifer (vertical) groundwater level differences [m]	0.1m (between bores); 0.05m (between pit water body and groundwater).	Assumed; any greater could negate these observations' value in some cases.
Pit water body water level [mAHD]	0.1 m (mAHD)	Assume survey and recording error is minimal, but account for relatively coarse temporal resolution of observations, and of water body bathymetry.
Mine pit sump pumping [ML/day]	+/-10%	Account for poor early records, potential metering and recording error, and that this is a "loose" constraint given it is used as an absolute upper limit of groundwater discharge to the pit (i.e., it includes in-pit runoff).
Stream Flow and flow differences [ML/day]	+/-10% (5% for annual flow volumes; 0% for zero flow)	Error would vary with flow volume. Flows from v-notch weirs possibly affected by gauge underflow. Some gauges are known to have been affected by debris after major events. Upstream and downstream channel morphology may affect gauged flow reliability.

5.2.2 PEST's Objective Function

Groundwater level and difference (trend), drawdown and surface flow and related data were assigned to a range of observation sub-groups as outlined in Section 5.2 and Table 5-1. This was undertaken to ensure adequate weight was placed on important observation data, and that contributions to history-matching error and optimisation progress, or lack thereof, could be easily identified and rectified during optimisation.

The effect of differing relative weighting within each observation group on PEST's objective function is presented in Figure 5-5, for the pre- and post-history matching cases (top and bottom charts respectively). It should be noted that:

- Several additional sub-groups were defined during history-matching, and hence there are additional groups present in the lower pie chart. These include surface water flows greater than 1 ML/day, to better direct PEST's attention to those components of the hydrograph.
- Relative weights were increased by a factor of ten on stream flow records post-2009 for gauge SV2, the record for which comprises two main periods – 1975-1982, and 2009-current. PEST was largely focussing on the observations from the earlier period while somewhat neglecting those from the latter period in early iterations; it was however considered more important to direct history-matching efforts to more recent records given their relevance to a drier catchment in which Alcoa's (and Barwon Water's) operations have changed substantially.
- Relative weights were increased on the groundwater level depth observations (for bores <30 m deep) to increase PEST's focus on these data, as they were being somewhat neglected in earlier iterations. Therefore, their apparent relative contribution to the objective function is larger in the bottom (posterior) pie chart than it is in the upper (prior) chart.

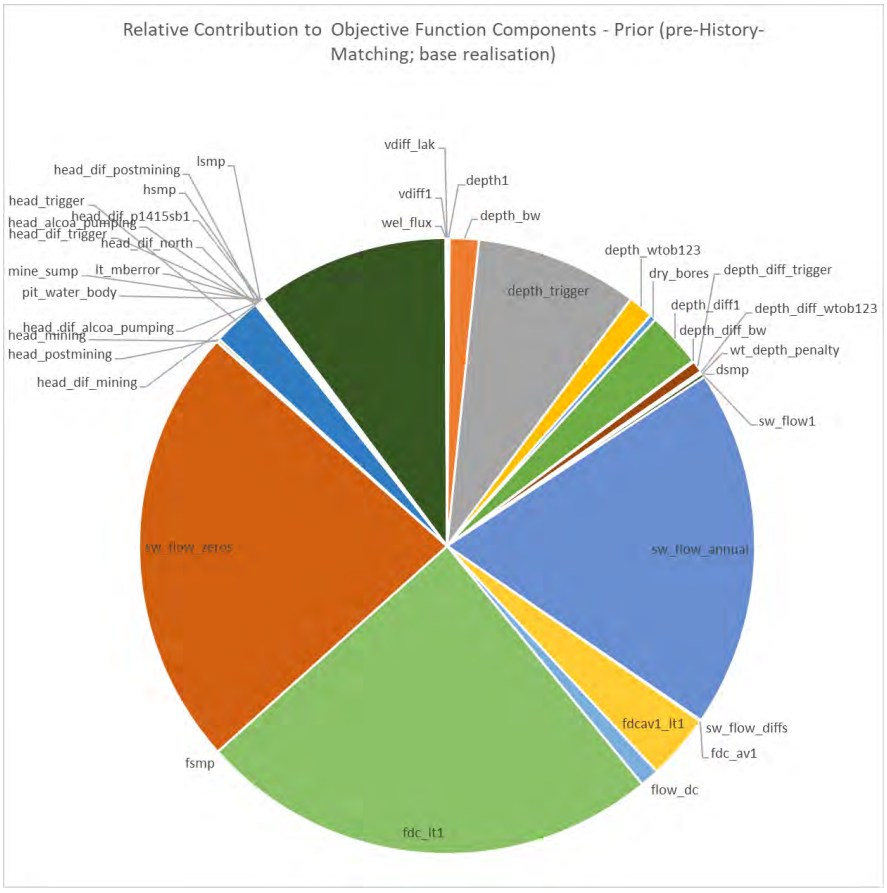
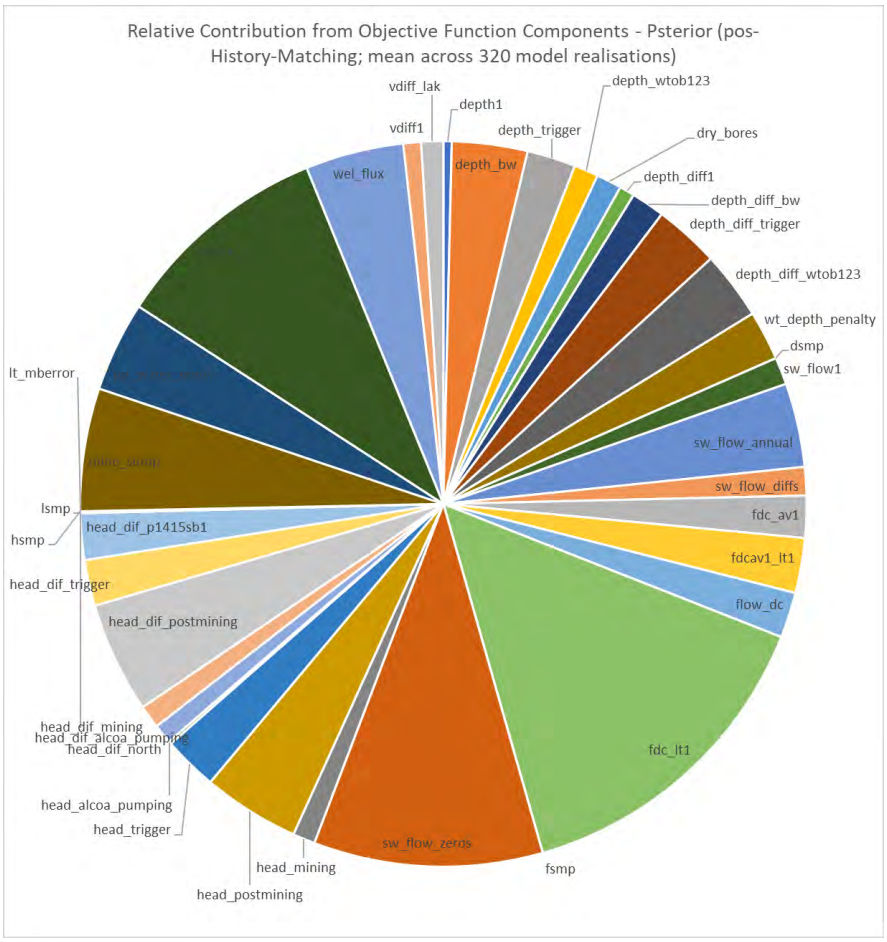
Figure 5-4 Model History Matching Workflow: Observation Data





Notes on acronyms:
wt – watertable (depth above ground penalty observations)
dif / diffs - difference (head; over time. Or Inter-station flow differences).
vdif - vertical (head) difference.
dc - duration curve (flow and watertable depth frequencies)
lt1 - less than 1 (ML/day flow)
sw - surface water

Other Notes:
1. Observation groups were refined during history matching; some groups were subdivided to focus PEST on specific observation types that were being "lost" among the broader groups. Hence the two charts' series are not identical.
2. The relative weight on depth observations (watertable; for bores <30m deep) was purposefully increased during history matching. Therefore, these group's relative size has increased between the prior (upper) and posterior (lower) charts.

Figure 5-5 Relative contribution of each observation group to PESTPP-IES' objective function

5.3 Parameterisation

Parameterisation schemes and allowable parameter ranges applied to the PESTPP-IES history matching process are outlined throughout Section 4, for boundary conditions and applied fluxes (Sections 4.5.1 through 0), and strata hydraulic properties (Section 4.6). However, some additional details with respect to PESTPP-IES in terms of model parameterisation are discussed below.

All pilot point (spatially interpolated) parameters described in earlier sections are assigned spatial covariance structures to encourage the history matching process to honour the initial ("prior", or pre-history matching) parameters and their spatial differences as closely as possibly, unless departures from this are necessary to significantly improve the simulation of historical system behaviour, as measured by PESTPP-IES against the strategically-weighted observation data outlined in the previous section.

These covariances are defined using PEST utilities MKPPSTAT and PPCOV_SVA (Doherty, 2016d). Variances are defined on the assumption that one quarter of the allowable parameter range represents on standard deviation, thereby implying a 95% confidence interval[24]. Covariances were defined using a variogram with range defined based on the mean distance from each pilot point its eight nearest neighbours. No nugget is applied.

For parameters that are not spatially correlated, standard deviations were defined in the same way (one quarter of the allowable parameter range). These standard deviations and covariance matrices were provided to PESTPP-IES via a PEST parameter uncertainty file (see Doherty, 2016b).

PESTPP-IES was instructed to optimise a total of 52,600 adjustable parameters, most of them comprising spatially variable pilot points representing a range of parameter types within each model layer.

5.3.1 The model parameterisation workflow

Figure 5-6 presents a summary schematic of the model parameterisation workflow developed and applied in the history matching process. Detailed discussion of each model package and how the conceptual model and supporting data is used to inform its' design and parameterisation is provided in Section 4 of this report (refer to each of the main sub sections).

PESTPP-IES, at the initiation of each optimisation iteration, first implements the parameterisation workflow shown in Figure 5-6 to update each model parameter of every model realisation in the model input files, and ultimately run MODFLOW-USG with those updated parameters (see the bottom of the figure).

Following parameterisation and running of the model in each optimisation iteration, the observation processing workflow discussion in Section 5.2 and shown in Figure 5-4 is executed by PESTPP-IES on each model realisation. PESTPP-IES then has the information that it needs to develop and test parameter upgrades for the next iteration.

[24] I.e., assuming a normal parameter distribution, given the 68-95-99.7% rule, these percentages of the sampled parameter set lie within 1/2/3 standard deviations of the mean. If we divide the allowable parameter range by 4, this represents two standard deviations around the mean - i.e., PEST's allowable range describes the 95th percentile interval. This is not really of great importance; the range could instead have been divided by six (implying a 99.7% confidence interval), and the sampled parameter distribution would have been narrower around the mean; but this is probably not reflective of true parameter and model uncertainty.

Figure 5-6 Model Parameterisation Workflow

6. Model History-Matching – Results

The following three subsections present and discuss history-match quality in terms of model performance, groundwater levels and stream flows. Subsequent sections present optimised parameters and their uncertainty.

6.1.1 Model performance

The model used for history matching (323 stress periods) takes anywhere from 1 to 8 hours to build, solve and post-process, depending on the model parameter realisation employed, computer hardware, and how many models are run at once per computer (many during the PESTPP-IES process, which slows the model down). The upper end of this run time is longer than ideal, and could be investigated and potentially reduced, given time and budget, to make the modelling process more efficient (and cost-effective) in future. The base model realisation however only takes only one hour to run, which is reasonable for a model of this size; gainable efficiencies may therefore be minimal.

During and at the end of the history-matching process, convergence and mass balance error details were checked, indicating generally very low mass balance errors in the combined steady-state / transient model. The mass balance errors are for the most part below the maximum 1 % error recommended by the Australian Groundwater Modelling Guidelines (Barnett et al., 2012), generally at less than 0.05% and always less than 0.3%.

PESTPP-IES semi-randomly explores the limits of parameters. On occasion this leads to numerical instability and/or failure to achieve convergence, and hardware/networking issues can also cause issues; of the 500 initial model realisations passed to PESTPP-IES, 237 were lost over the optimisation iterations (totalling thousands of model runs); this leaves a pool of 263 optimised models from which to select a subset for ongoing application in scenario modelling. From a practical point of view, this is a positive outcome considering the tens of thousands of randomly varied parameters, thousands of simulations, the application of two strongly non-linear boundary conditions (in places within the same model cell (SFR2 and EVT)), and other significant non-linear stresses associated with historical mining and groundwater pumping effects.

6.1.2 Optimised Model Realisation Sub-Setting

For the purposes of history matching, no realisation sub-setting is implemented in this case, beyond that described above for mass balance reasons. For predictive purposes however, it is expected that a smaller, more manageable number of model realisations will be selected for application in that case (e.g., the top 150 models of higher history match quality).

6.1.3 Groundwater levels

Summary history-match statistics for heads in bores deeper than 30 m are presented in Figure 6-1, and those for watertable depths in bores less than 30 m are presented in Figure 6-2. These include uncertainty across the 263 history-matched model realisations as both statistics and repeated grey chart series; statistics and series for the base realisation are also presented in these figures.

Figure 6-1 shows root mean square and absolute mean errors are reasonable for absolute levels (3.5-5.8% and 7.1-12.5 m respectively), considering the effect of recognised levels of observation noise (including recognition of aged observation bores), uncertainty in historical pumping rates and mining depths, in conjunction with model spatial resolution and its topographic errors. Also contributing to these model errors is the low weighting that was placed on Alcoa production bores' head data for periods over which they were historically pumped on a sub-daily basis, which the model cannot replicate given its temporal resolution. The full unweighted data set is presented in Figure 6-1, and are included in the statistics and plots presented throughout this report section. The cumulative residual plot on the left side of Figure 6-1 shows that approximately 75% of absolute head observations (for deeper bores) are within 10 m error, and approximately 90% are within 20 m (against observation data spanning more than 250 m range), across all 263 model realisations.

Figure 6-2 shows absolute mean error for watertable depths is small for a regional scale model (0.8-1.4 m), and the root mean square error is reasonable (7.2-13.5%) given the narrow range of observation data for groundwater depths. The cumulative residual plot on the left side of Figure 6-2 shows that 70-80% of watertable depth observations are within 1 m error, and more than 85-95% are within 5 m error, across all 263 model realisations.

The largest watertable depth outliers in Figure 6-2 tend to be for sparse (or even single) readings in the many very shallow (often sub-5 m) Alcoa observation bores around the old power station site, which may monitor shallow perched systems, and some of which are known to have been historically affected by local leakage from site infrastructure – the effect of which is not explicitly modelled, because it is not material to the model objectives. Model layering around these shallow bores, as provided by Alcoa, may also require further investigation and refinement if this is deemed an important issue. In any case, it is clear from the scatter plot on the right side of Figure 6-2 that observation bores with longer timeseries (evident as larger clumps of many points, most often with a diagonal trend) are better simulated by the model than those with far fewer sparse readings.

Maps showing the spatial distribution of mean residual (the difference between modelled and observed values) are presented in Figure 6-3 and Figure 6-4. These maps show:

- Minimal error and no evident bias in the spatial distribution of residuals for the ASA (upper map in Figure 6-3).
- Larger but still minimal error in the shallow (DBF, Boonah Formation) bores around the Alcoa site, which are known to be affected by historical leakage from site infrastructure (lower map in Figure 6-3). There is no clear pattern in their spatial distribution, and therefore no evident spatial bias. It is worth noting the very short period of record for these bores, and the relatively low weighting placed on them in the history matching process.
- A generally good groundwater level history match quality in the UEVF upper sands aquifer within and around the historical Alcoa mine pit (top left map in Figure 6-4). This is significantly improved over earlier model history matching efforts, which was enabled through more flexibility in the simulation of historical mining operations (see Section 4.5.9). Head in bore UEVF_MB8 (monitoring a UEVF intermediate coal sub-unit) to the west of the mine is however underestimated by more than 10 m; this is probably due to the discrete nature of the coal seam interval monitored within the broader and much thicker intermediate aquifer.
- A highly mixed picture of model over- and under-estimation of groundwater levels in the UEVF lower sands aquifer around the Alcoa coal mine (top right map in Figure 6-4). Whilst recognising that drawdown (stress responses, not absolute heads) is the focus of the history matching (see further discussion on this below), this possibly reflects:
    - the highly variable nature of this aquifer,
    - the various sub-units that may be screened by each of these bores,
    - the low history-match weighting placed on the Alcoa production bores during periods of historical sub-daily pumping, which the model cannot replicate due to its temporal resolution; and
    - their age, which tends to lead to poor bore condition.
- To the north of the Alcoa mine, in the northern syncline, the top right map of Figure 6-4 shows minor model residual error for most bores (e.g., NB2, 116458, P19, 121768). However, for Barwon Water's ASR bores which have very short periods of record (typically possessing only one observation each), there is a tendency for increasing model over-estimation of heads in the northerly direction; this appears to be a highly localised issue and is of no consequence to model utility.
- In the LEVF aquifer, the bottom map in Figure 6-4 shows generally negligible mean residual error in the upper catchment areas, and moderate to high levels of residual error in the deeper parts of the basin around the Alcoa coal mine; the largest outliers are generally Barwon Water production bores, with most head error occurring in some model realisations (but not all) under peak pumping stress for short periods; this is not uncommon when trying to simulate production bore heads, given model cell scale and the complexities of well efficiency losses. There is a general pattern of head over-estimation to the southeast of the Alcoa mine, and very slight under-estimation to the west. Broadly speaking, magnitudes of drawdown (i.e., pumping stress response) away from production bores are the focus of the history-matching and are generally well simulated (see Figure 6-6 and Appendix D, the further discussion on this below).

Absolute head and watertable depth hydrographs for all observation bores used in history matching are presented in Appendix D and Appendix E respectively. These include uncertainty across the 263 history-matched model realisations, shown as grey lines. *An important point to note in all model groundwater level and stream flow hydrograph figures presented in this report, is that there are periods of apparently greater variability in the late 1970's to early 1980's, and again in the late 2000's, than there is in intervening periods; readers should recall that this is driven by coarser temporal model discretisation (up to annual stress period durations) in the intervening periods, as is described in Section 4.4 and Figure 4-8.*

Modelled head hydrographs generally show a reasonable to good match to their observed counterparts, although there are exceptions where a poorer match is evident. The following general observations are made with respect to the history match quality to absolute heads (for deeper bores):

- Appendix D shows that absolute heads and more importantly drawdown trends over time (in response to groundwater pumping, primarily by Alcoa from 1968 through to 2022 and Barwon Water from 2007 to 2022), are well simulated. For example, the Alcoa WB* bores and Barwon Water bore SB2, screening the lower UEVF aquifer (see examples in Figure 6-5); and Barwon Water's GW* bores, SB1 and P* bores screening the LEVF aquifer (see examples in Figure 6-6). The broad UEVF aquifer trends in response to long-term, large-scale hydraulic stresses from Alcoa mine development and groundwater pumping for the power station and mine depressurisation are generally well simulated (Figure 6-5 and Appendix D). Similarly, the LEVF aquifer responses to historical Barwon Water borefield use are well simulated (Figure 6-6 and Appendix D). These are positive outcomes from the point of view of model performance, given that potential effects arising from these two major stressors are the primary reason for model development. As with any model, there are exceptions to the above general statement. These include:
    - Absolute heads in many model realisations for LEVF bores in the shallower western parts of the northern syncline (119347 (Figure 6-6; not all realisations), P13, 113004 and P3 (Appendix D)) tend to be over-estimated by 5 m. To the east however, in deeper parts of the syncline, head and drawdown trends are generally well simulated.
    - There is a lack of modelled drawdown at UEVF bore 115868 as compared with observed data (Appendix D): The sharp decline in 2010 coincides with LEVF Barwon Water's pumping (see nearby LEVF bore P15 in Appendix D), and the head it declines to (-25mAHD) also coincides with LEVF heads around that time. But the subsequent recovery post-Barwon Water's pumping is not observed. It is likely that this bore is of poor integrity, possibly with some connection to the LEVF (e.g., a temporary unblocking under LEVF pumping stress in 2010). *It is important to stress that DELWP have categorised this bore as having failed, and it is no longer monitored by DELWP.* It is noted that UEVF bore 116459 (located at the Alcoa pit west wall) does not draw down to anywhere near -25mAHD at this time, despite being immediately adjacent the pit; neither do those immediately around Alcoa's production bores (WB16 etc). This suggests that bore 115868 is certainly connected to the LEVF in some way but is clearly of poor integrity. The old government bores were not constructed to standard and therefore their reliability is low.
        - Similar, related issues affect other government bores: for example, 115867 (LEVF), and 116459 (UEVF); (refer Appendix F).
- Alcoa's UEVF lower sand bores (WB*) often exhibit a mix of over-and under-estimation during the active mining period (Figure 6-6 and Appendix D); at these times, the Alcoa production bores were intermittently pumped on a sub-daily basis, which the model cannot replicate given its temporal resolution. There is also uncertainty regarding historical Alcoa mining depths. A low weight was placed on these observations during history-matching (primarily because of the intermittent sub-daily pumping schedules), and a higher weight was placed on post-mining heads and recovery trends, which are better simulated.

The following general observations are made with respect to history match quality to watertable depths (for bores shallower than 30 m):

- Appendix E and Figure 6-7 show that watertable depths in ASA bores are generally well simulated across all 263 model realisations, in terms of the average depth below (or above) ground, and in terms of seasonal and longer-term trends and variability. For example, see bores P10, P13B, P17, WTOB1 and WTOB2 (Figure 6-7), WTOB3, P7, P7B, P18, and P1. This is also a positive outcome because these observations are of importance to groundwater system behaviour directly related to some of the key modelling objectives (see Section 2.1). Points of note follow:

    - The large differences in watertable depth between P13B (19-20 m) and P18 (1-3 m), despite these bores being located closely together, are due to large local topographic changes. P13B is located on top of a scarp, above the valley floor where P18 is located.
    - Exceptions of poorer ASA history match quality include P9 and P8, with many realisations tending to exhibit shallower watertable depths than is observed by 0.5-1 m (Appendix E). In the case of P9, seasonal fluctuations are also over-estimated by the model, with the observed data showing little to no fluctuation; given the rarity of this behaviour in the observation data set, this could indicate that bore P9 screens a discrete, relatively impermeable lens of sedimentary material, because it's behaviour is not representative of the general behaviour of the watertable throughout the rest of the catchment (Figure 6-7 and Appendix E).
- Appendix E also shows that watertable depths in Alcoa's shallow Boonah Formation bores are reasonably well simulated, although are often under-estimated by the model by 2-5 m. Similar can be said of the history-match to the sparse data from many of Alcoa's shallow DBF bores.
- Also of note is that many shallow Alcoa MW* bores display sill-like (at times flat-lining) hydraulic behaviour. This is due to the very thin DBF layer in much of the Alcoa site being extremely thin and shallow, and therefore this model layer dries out at times in various places.
- Shallow LEVF bores (P11, P16, P6, WTOB4) and UEVF bores (P19) are all very well simulated in terms of seasonal and longer-term trends in watertable depth (Appendix E).

Figure 6-8 presents watertable depth-frequency history matching curves for all Barwon Water bores less than 30 m deep. These generally show good agreement with the observed data in terms of frequency trends and absolute depths; the main exceptions being P9 and P8, as is described above. This is an excellent outcome given the importance of these curves, and the watertable behaviours that they represent, to acid generation risks.

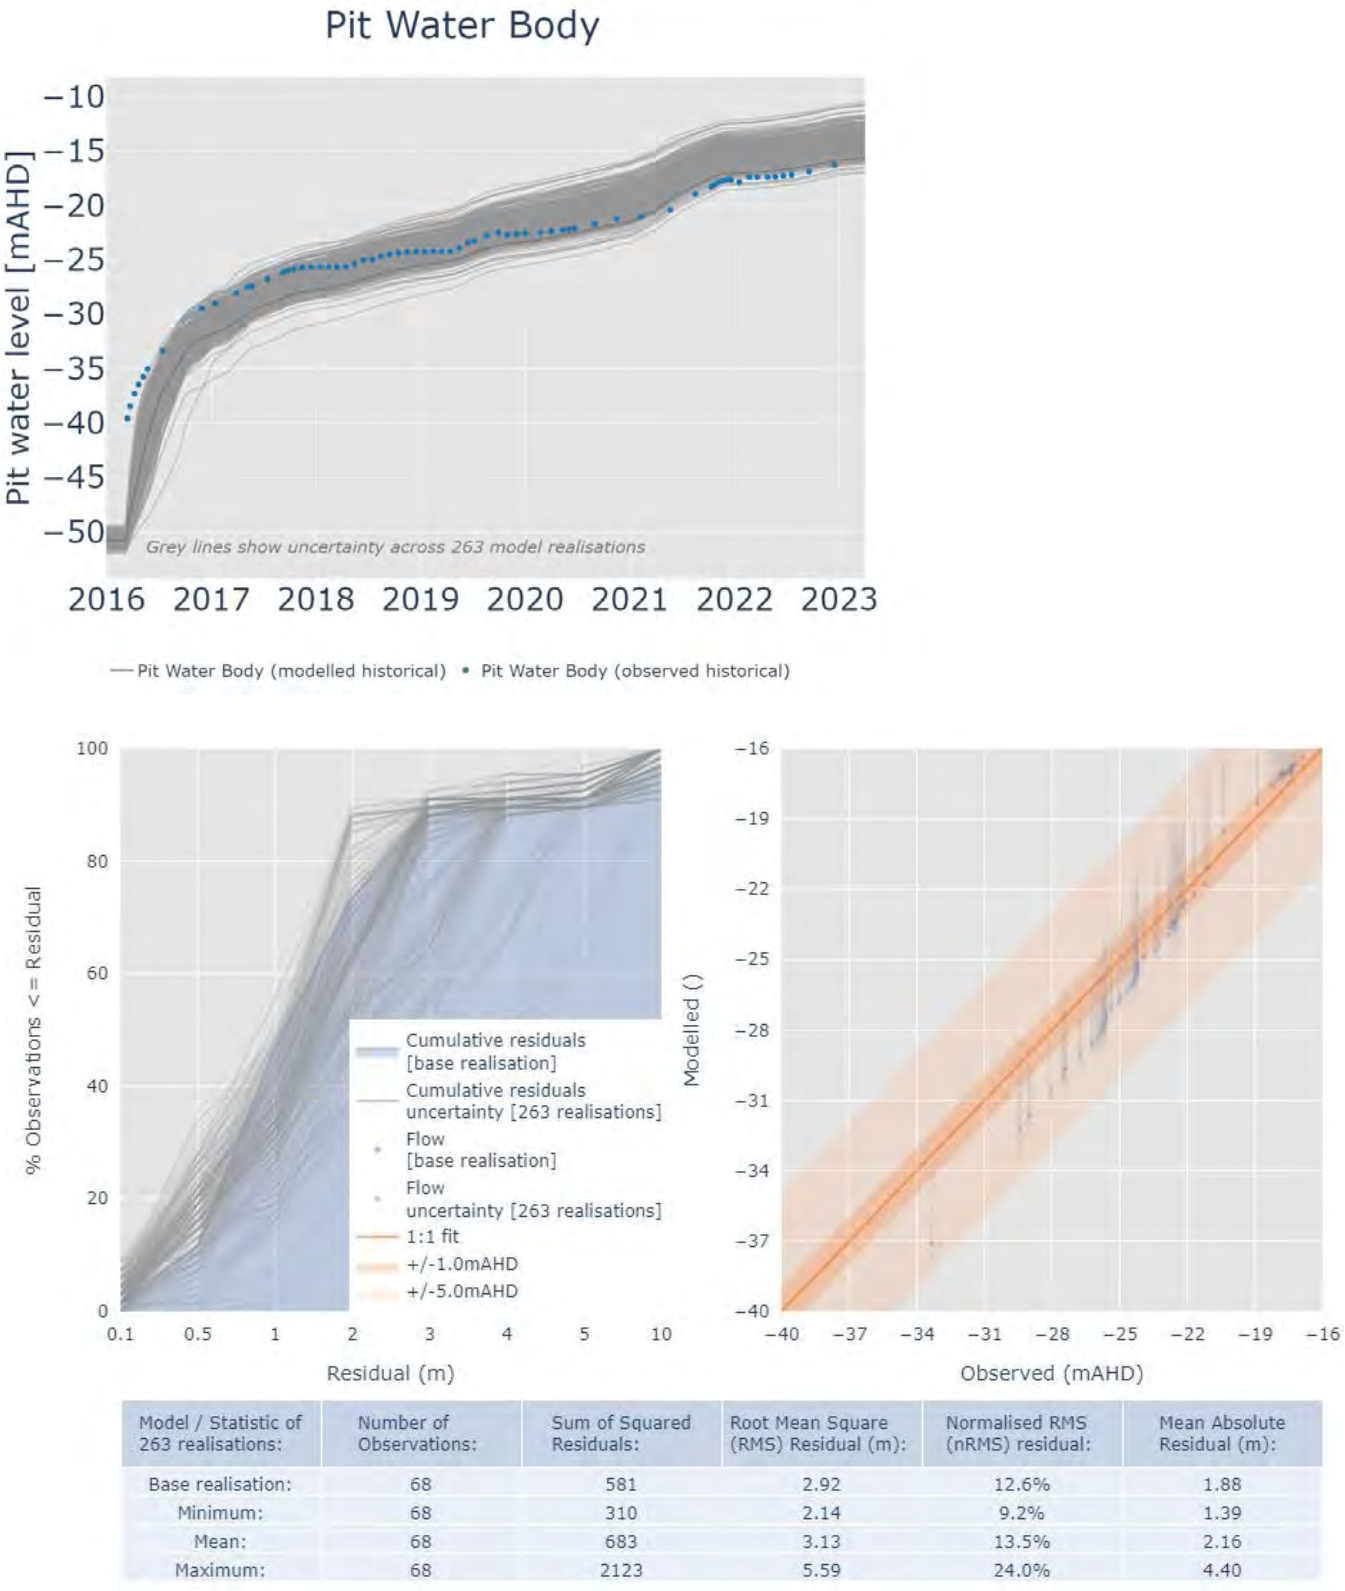
6.1.4 Pit Water Body Levels

Figure 6-9 presents the modelled versus observed pit water body levels for the Alcoa mine void, post-mine closure. Absolute water levels and temporal trends are very well simulated by all 263 model realisations. For many realisations in later time (2019 onward), errors are generally within 2.0 m and temporal trends are well simulated.



Model / Statistic of 263 realisations:	Number of Observations:	Sum of Squared Residuals:	Root Mean Square (RMS) Residual (m):	Normalised RMS (nRMS) residual:	Mean Absolute Residual (m):
Base realisation:	68	581	2.92	12.6%	1.88

Mean:	68	683	3.13	13.5%	2.16
Maximum:	68	2123	5.59	24.0%	4.40

Figure 6-9 Model history matching to pit water body levels

6.1.5 Stream flows

Figure 6-10, Figure 6-11, and Figure 6-12 present stream flow history matching hydrographs for the upper and lower Anglesea River, Breakfast Creek, Breakfast Creek tributary, and for Salt Creek, respectively. Corresponding flow duration curves are presented in Figure 6-13. *Readers are reminded that all model groundwater level and stream flow hydrograph figures presented in this report exhibit periods of apparently greater variability in the late 1970's to early 1980's, and again in the late 2000's, than there is in intervening periods; readers should recall that this is driven by coarser temporal model discretisation (up to annual stress period durations) in the intervening periods, as is described in Section 4.4 and Figure 4-8.*

Figure 6-10 shows that flow magnitudes and their intermittency at the lower Anglesea River gauge is well simulated across all 263 model realisations; in the upper catchment however (AV1), the model tends to underestimate the frequency and magnitude of flow events; this may be a consequence of placing too great a relative weight on the history match to nearby shallow observation bores.

In the upper tributary areas of Salt Creek, Figure 6-11 shows that flow frequencies and magnitudes at both gauges SV1 and SV3 are generally well simulated, if not slightly overestimated at the lowest of flows at SV1 (around 2E-2 ML/day or less). Figure 6-12 shows the history-match quality to gauged flows in Salt Creek (at Denham Track, SV4) and in the lower Salt Creek near the Alcoa mine (SV2). Simulated gauged flows at SV2 match the observed flows closely, both in terms of the magnitude and frequency - the typically very sporadic flows at SV2 are well simulated. At SV4 low flow magnitudes and durations also tend to be well simulated.

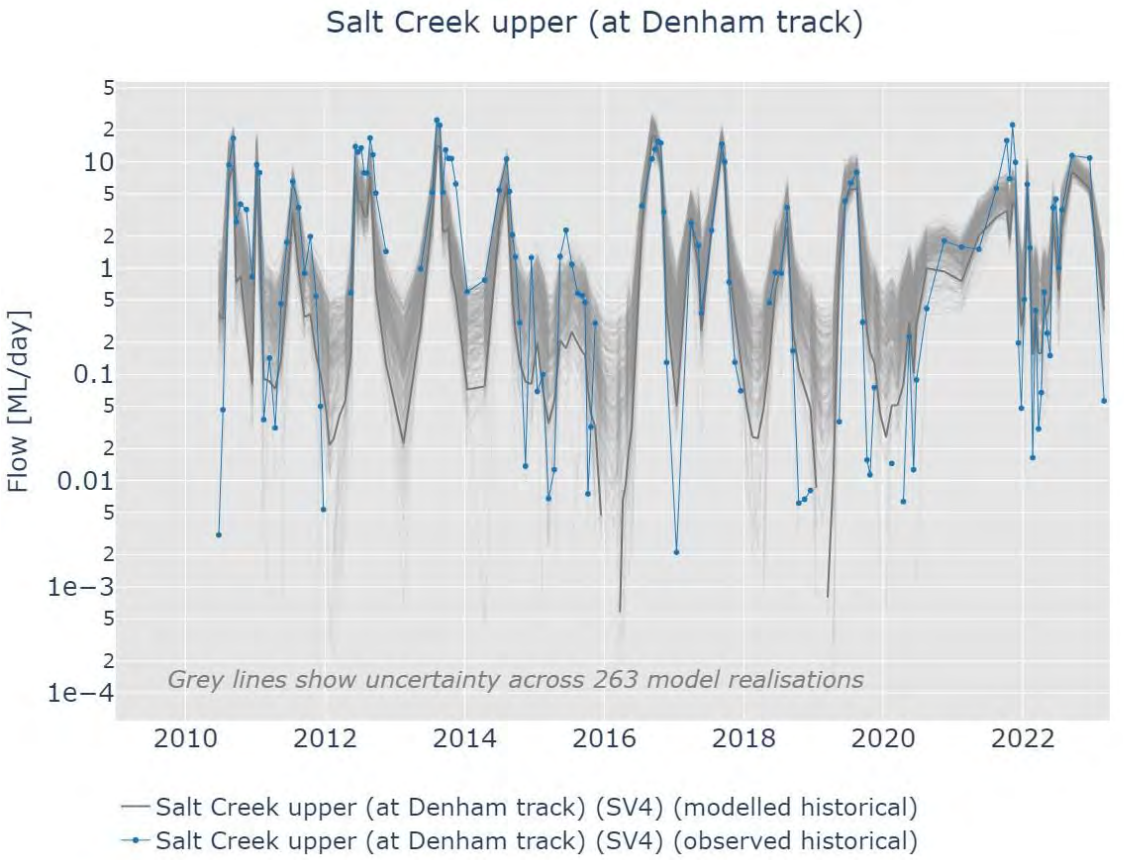

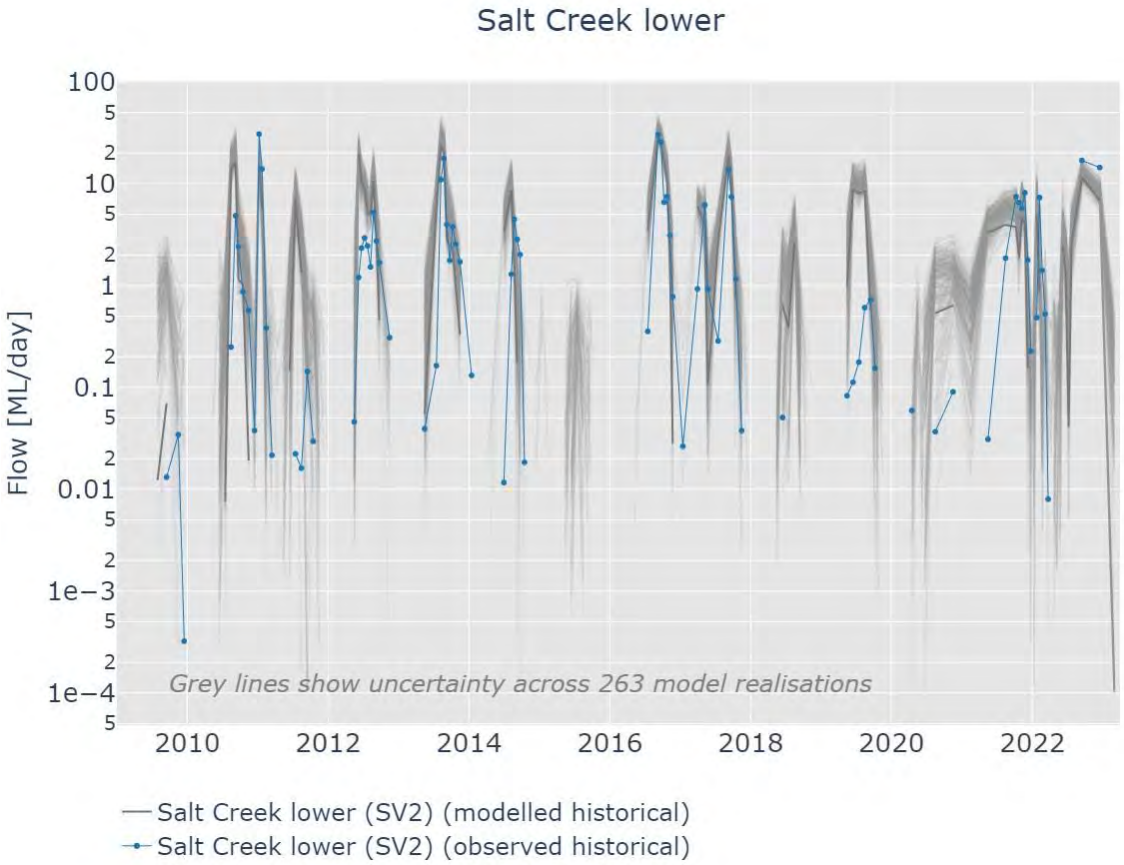

Figure 6-12 Model history matching to Stream Flows – Salt Creek

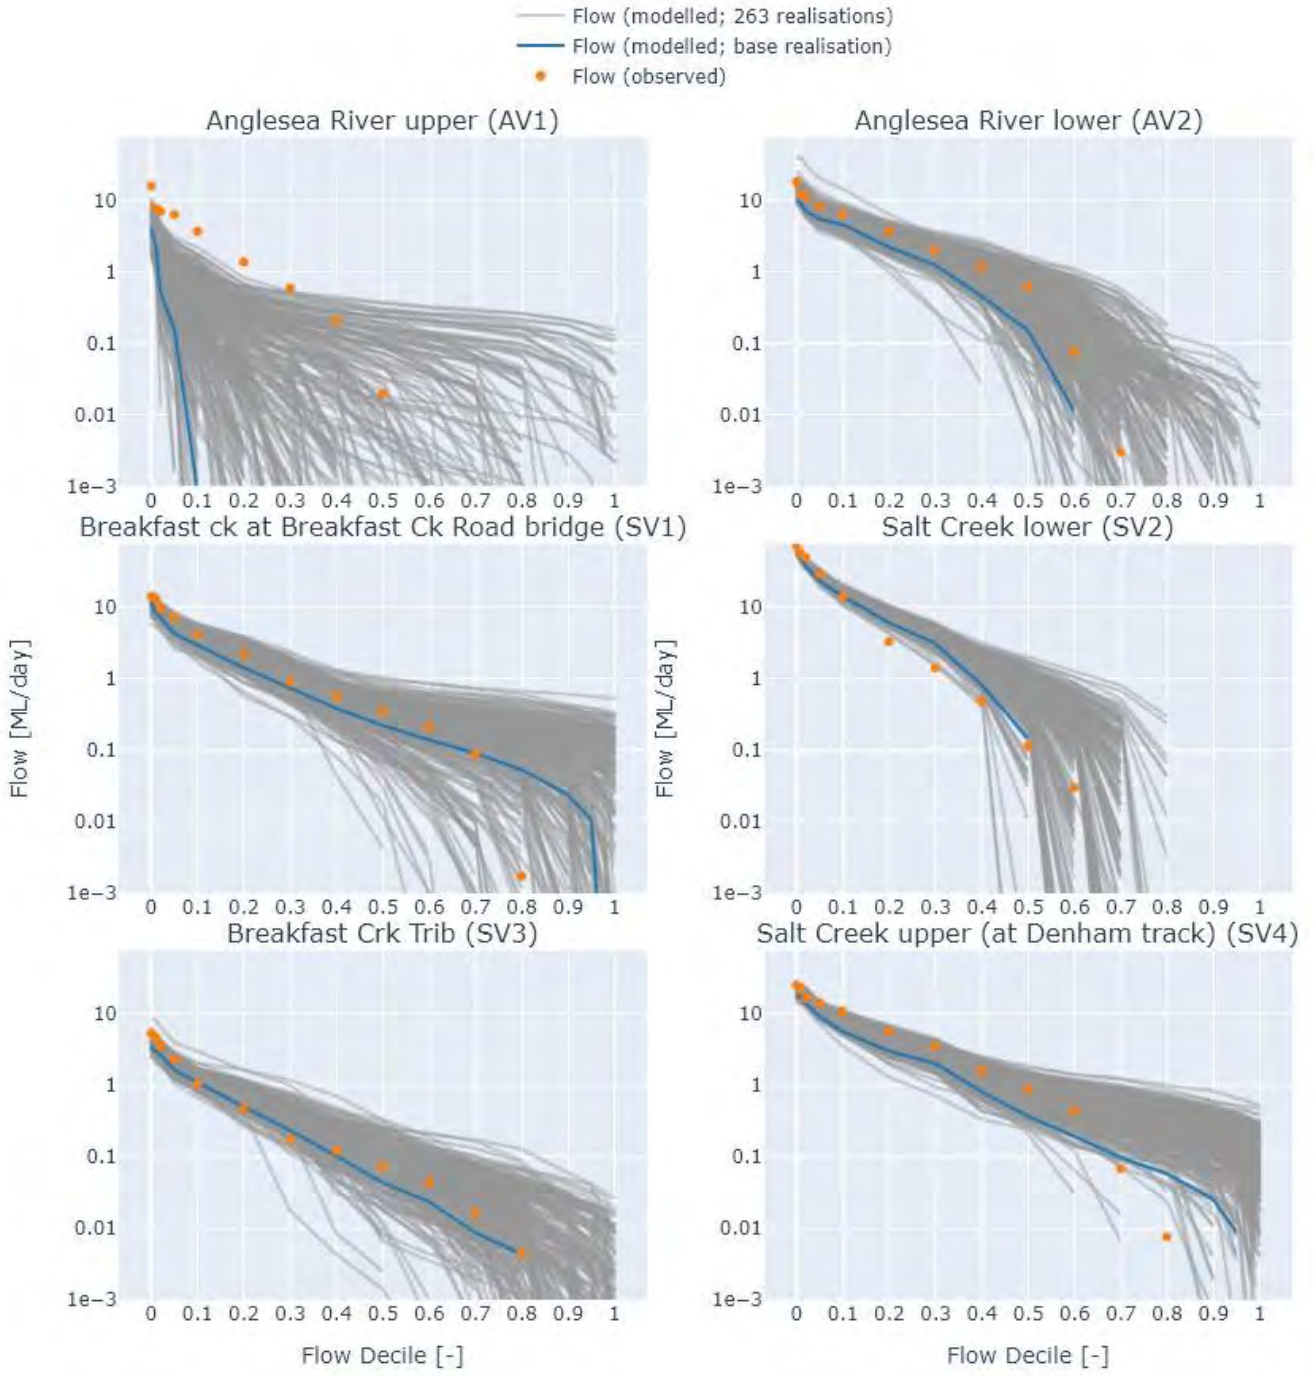

Figure 6-13 Model history matching to Stream Flow Duration Curves

6.1.6 Modelled cause-and-effect behaviour

Putting the above history-matching types together, Figure 6-14 and Figure 6-15 show modelled cause-and-effect responses to various aquifer stressors (pumping, climate) over the last decade; these are presented for lower Salt Creek and lower Anglesea River, respectively. These figures show that the model does a good job of simulating the observed dominance of historical rainfall trends (grey line in the upper-most charts) over groundwater pumping (middle charts) and mining on shallow watertable levels in the ASA around the Alcoa mine and Barwon Water's Anglesea borefield (upper charts). Observed and modelled surface water flows (lower charts) generally follow the same rainfall-dominant trends as does ASA watertable depth (upper charts).

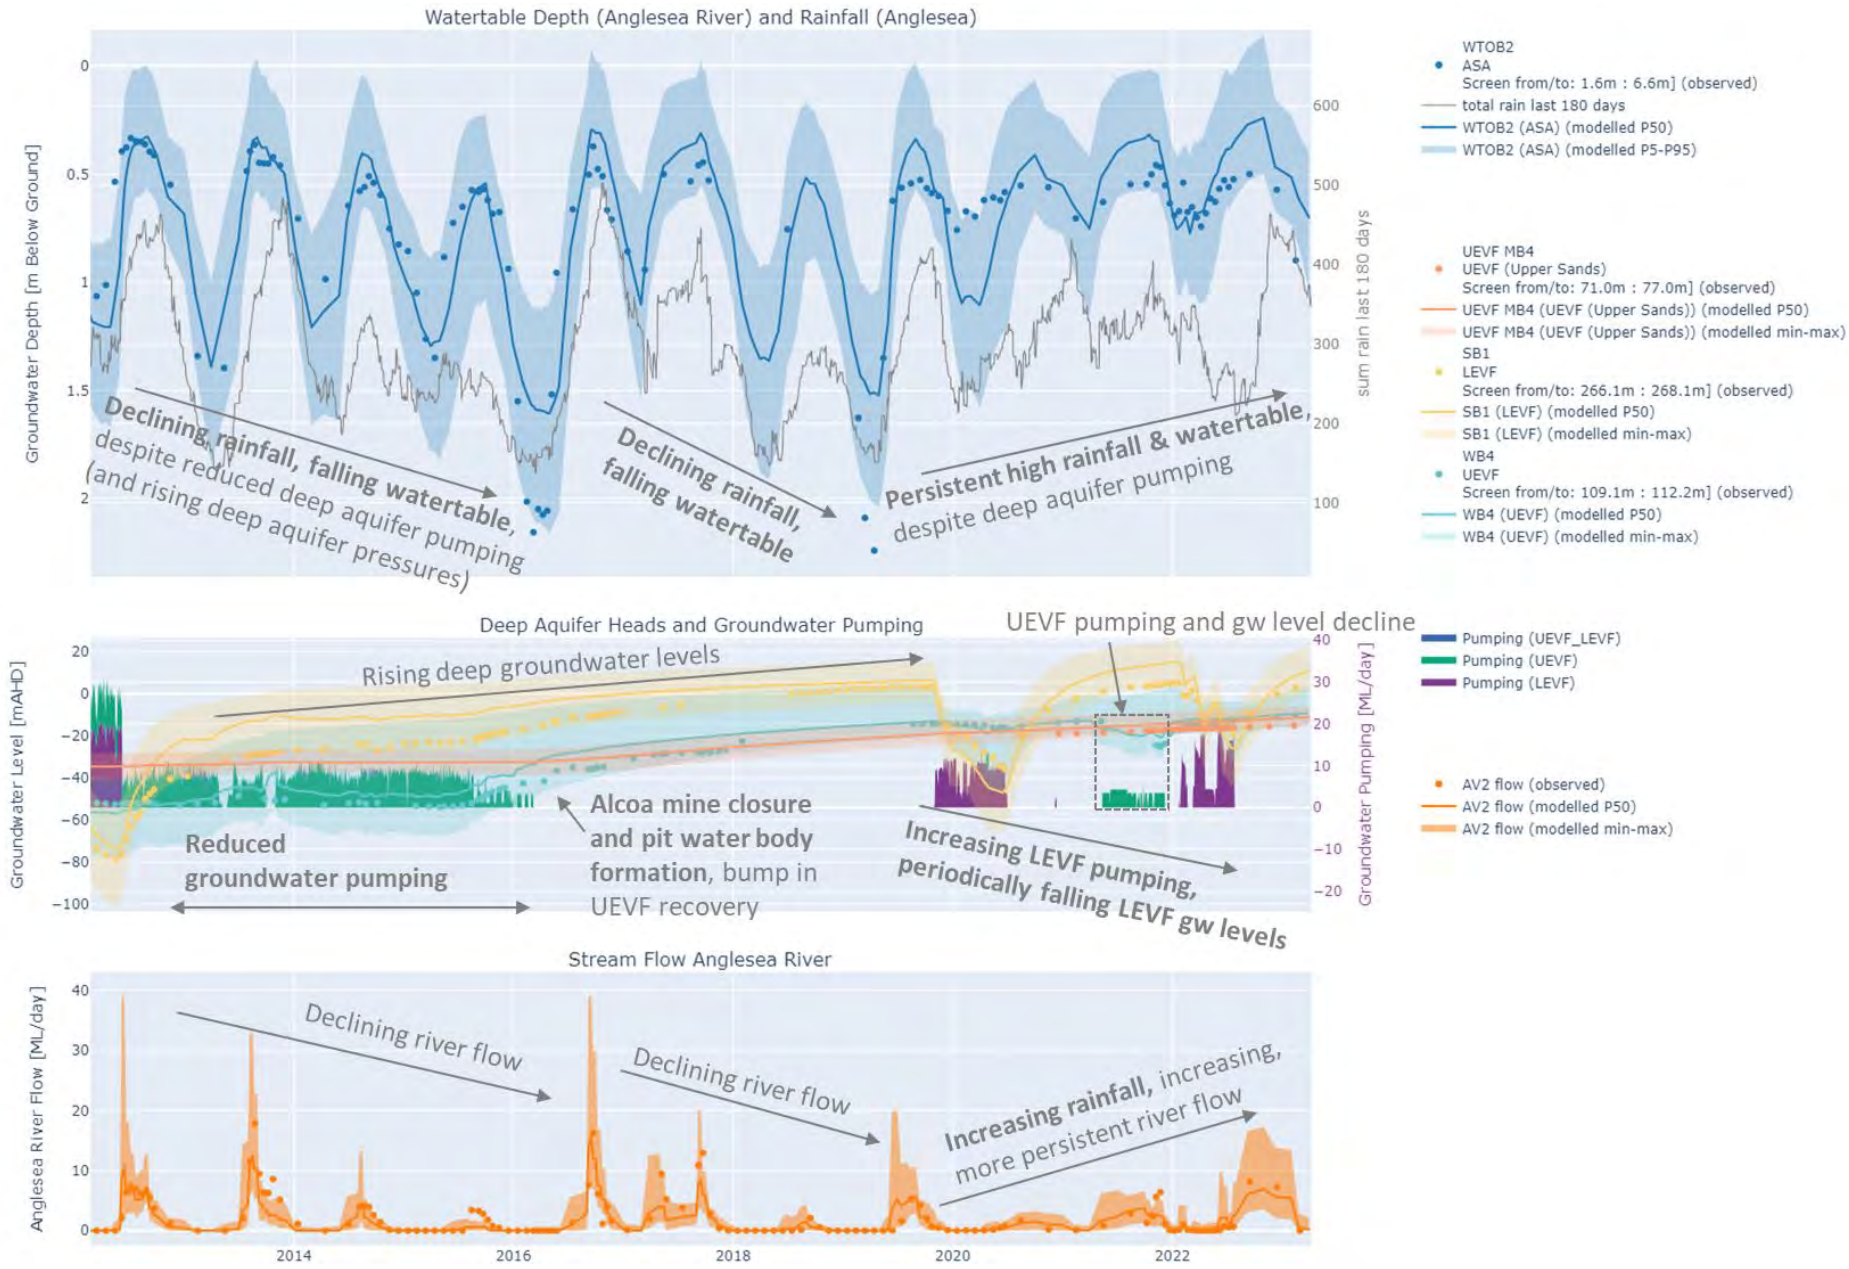

Figure 6-15 Model history matching: stress response cause-and-effect processes [lower Anglesea River]

6.1.7 Optimised parameters and their uncertainty

Horizontal Hydraulic Conductivity

Optimised base realisation horizontal hydraulic conductivity parameters are presented in Section 4.6 and Figure 4-19 through Figure 4-23. Figure 6-16 through Figure 6-20 present corresponding model parameter uncertainties around that base realisation, across the 263 history-matched models. These are presented as the ratio of maximum to minimum values in each model cell on the left side of the plots. On the right side of each plot are maps showing the reduction in uncertainty from the prior (pre-history matching) to the posterior (post-history matching) throughout the model domain; the measure used to show this is the normalised reduction in parameter variance across the 263 parameter set realisations.

The parameter range plots on the left side of Figure 6-16 through Figure 6-20 (top for Figure 6-16) indicate generally significant posterior horizontal hydraulic conductivity uncertainty, typically in the order of 1-3 or more orders of magnitude. The most notable exception to this is the MEVF (Figure 6-19), which exhibits a lower uncertainty range (5-50); on face value this may suggest that the permeability of this regional aquitard is of strong importance to history-match quality, but it is important to note the allowable range for this unit is lower relative to that of other model layers (Table 4-6).

The parameter uncertainty reduction plots on the right side of Figure 6-16 through Figure 6-20 (bottom for Figure 6-16) indicate 75-95% reduction in horizontal hydraulic conductivity uncertainty, from pre- to post-history matching. These relatively large reductions are partly a symptom of the very wide allowable ranges specified at the outset of the process; see Section 4.6, particularly Table 4-6, which shows 5-6 orders of magnitude allowable range for most model layers, the exception being the MEVF (3 orders of magnitude). Perhaps of greater interest is the spatial variability in uncertainty reduction in these maps. For example, the largest uncertainty reductions in LEVF hydraulic conductivity (right side of Figure 6-20) are around the Barwon Water borefields of the northern and southern synclines; this is a direct outcome of the fact that these are the dominant historical aquifer stress locations in this unit.

The key point from these maps is that there is a significant range of residual horizontal hydraulic conductivity represented in the 263 history-matched models, in all layers and in most areas of the model domain; this will carry through to a degree of uncertainty in scenario model forecasts of effects from Barwon Water and Alcoa water development operations. Similar can be said for other model parameters, which are now discussed.

Vertical Hydraulic Conductivity

Optimised base realisation vertical hydraulic conductivity maps are presented in Figure 4-24 through Figure 4-28.

Figure 6-21 Through Figure 6-25 present similar maps as discussed above for horizontal hydraulic conductivity, but for *vertical* hydraulic conductivity. On the left side of these figures, the ratio of maximum to minimum vertical hydraulic conductivity is shown to be consistently wide across the 263 history matched model realisations (typically 100-1000). Some layers exhibit a narrower range than others, but as was the case for horizontal hydraulic conductivity, this is in part a reflection the initial allowable ranges within each layer. One of the more interesting features in these plots is the marked comparatively wider vertical hydraulic conductivity range in headwater valley floors (i.e., beneath stream boundaries) on LEVF outcrop, compared with the narrower range on the interfluves (see top left map in Figure 6-25); this is also apparent with regard to horizontal LEVF hydraulic conductivity, but to a far less stark degree (Figure 6-20).

The maps on the right side of Figure 6-21 through Figure 6-25 show the relative reduction in parameter variance within each layer, as achieved through the history matching process (i.e., from the prior to the posterior). History matching has typically reduced parameter uncertainty by 50-95%, with lesser reductions tending to occur away from historical stress locations such as the Alcoa mine and power station, and the Barwon Water borefields (for example in the offshore areas (Figure 6-22 and Figure 6-24)), and the two Barwon Water borefields.

Aquifer Storage

Optimised base realisation parameters for specific storage are presented in Section 4.6 and Figure 4-29 through Figure 4-32; corresponding figures for specific yield are shown in Figure 4-33 through Figure 4-37.

The post-history matching ranges of specific storage and specific yield values across the 263 model realisations are presented in Figure 6-26 through Figure 6-30, for all model layers. The reduction from prior to posterior uncertainty is not presented for these parameters, for sake of brevity, given that these parameters are typically of lesser significance to history matching and model forecasts. These maps show typical ranges of a factor of 5 to 50 for both specific storage and specific yield; this relatively narrow range is primarily a reflection of the narrow allowable ranges defined in Table 4-7. But again, there is significant posterior parameter uncertainty for aquifer storage parameters, which will carry through to scenario model outputs.

Groundwater Recharge

The maps on the left side of Figure 6-31 presents the modelled median average annual recharge rates across the 263 history matched model realisations, for two different time periods: 1968-2000, and 2001-2023. These show that optimised recharge rates are higher in the 1968-2000 period (pre-Millennium Drought) than they are in the latter period. Estimated recharge rates are highest in the higher rainfall areas of the northwest and west (typically 20-100 mm/year), where the LEVF aquifer outcrops, and diminish towards the Alcoa coal mine and Anglesea, and somewhat to the east too, where the DBF is at outcrop (typically 1-20 mm/year).

The maps to the right side of Figure 6-31 show the post-history matching uncertainty range in recharge to groundwater, as measured across the 263 model realisations. There is significant recharge rate uncertainty across the model domain (typically 30-200 mm/year). There is relatively low uncertainty on the MEVF outcrop where recharge rates are consistently low, and in the mid reaches of the Anglesea River on ASA outcrop; this latter point is largely driven by model history matching to WTOB3 (which exhibits a deep watertable) and to the intermittent stream flows at gauge AV2.

Evapotranspiration from Groundwater

Figure 6-32 presents similar maps to those described above for recharge but pertaining to the post-history matching maximum *potential* evapotranspiration rates from groundwater, and their uncertainty. The maps on the left show the highest potential evapotranspiration rates in the east and coastal southeast of the model (including around the Alcoa coal mine and Anglesea), and lower rates to the west and northwest. The maps to the right side of Figure 6-32 show the wide posterior uncertainty range for maximum groundwater evapotranspiration rates; the narrowest range of uncertainty is on MEVF outcrop, because recharge variability is low and hence so is PE-AE (see Section 4.5.7).

Figure 6-33 Presents the corresponding maps for evapotranspiration extinction depth and its uncertainty. There is little evident spatial trend in these data, although there are localised areas of relatively higher extinction depth around some Baron Water observation bores, particularly in the upper Salt Creek catchment. Also evident is the relatively consistent shallow extinction depths in the east of the model; this corresponds with a gradual easterly change from forested land cover in the west (Otway range flanks) toward the eastern largely pastural areas. The extinction depth uncertainty range maps on the right side of Figure 6-33 tend to show the largest uncertainties in the areas of deepest optimised extinction depth.

As is noted for other parameters above, the evapotranspiration parameter and uncertainty maps presented show significant residual post-history matching uncertainty in these parameters, which will carry through to uncertainty in scenario model forecasts of water development effects.

Pit Water Body (LAK) Parameters

Table 6-1 summarise pit water body model parameters and their uncertainty across the 263 history matched model realisations. These show significant residual range around the means, which will carry through to uncertainty in model forecasts related to pit water body behaviour and its effects on and interaction with the surrounding groundwater systems.

Table 6-1 Pit Water Body – Optimised parameters and their uncertainty across 263 model realisations

Parameter	Description	Units	Average (geomean for LAK bed kv)	Minimum	Maximum
lak_hkfactor1	Pit water body wall horizontal leakance as a factor of aquifer hk (layer 1)	-	3.02E-02	1.31E-04	1.00E+00

lak_pan	Pit water body pan evaporation factor	-	8.24E-01	6.70E-01	9.62E-01

Stream (SFR2) Boundary Bed Hydraulic Conductivity

Figure 6-34 presents stream (SFR2) boundary bed hydraulic conductivity parameters and their uncertainty across the 263 history matched model realisations. The upper map shows bed hydraulic conductivity values for the optimised base realisation. This shows significant spatial variability (facilitated through pilot points, as described in Section 4.5.8). A reasonably clear pattern that has emerged is comparatively high bed hydraulic conductivity (darker browns in Figure 6-34) in streams flowing over outcropping ASA, UEVF and LEVF. In contrast, in areas on and around MEVF outcrop, there is a pattern of relatively lower bed conductivity.

The lower map shows the uncertainty range, measured as a ratio of the maximum to minimum bed conductivity across the 263 model realisations. As is evident from all other parameters, these show significant residual range, typically from 2 to 5 orders of magnitude; but it is also clear that there is comparatively low uncertainty in bed conductivity (1-50) in those higher conductivity areas on outcropping UEVF, LEVF, and to some degree ASA, as described above.

6.1.8 Model Water Balance

It is important for readers to note that results presented in this section are from a single model ("base") realisation - one of 263 history-matched realisations developed; that is, this is one of 263 estimates, and there is uncertainty around the estimates presented.

Modelled historical water balance summaries from the optimised base realisation are presented in Figure 6-35 and Figure 6-36 for the Anglesea (southern) and Jan Juc (northern) synclines, respectively. These show period averages over the 1968 to 2000 wetter climatic period, and the drier period from 2001 to 2022. In both basins in both time periods, the dominant model inflow component is recharge. The dominant outflow components are evapotranspiration from shallow groundwater, and offshore discharge.

Recharge is estimated to have fallen sharply between the two periods – by 43% in the Anglesea (southern) syncline, and by 47% in the Jan Juc (northern) syncline. This results in an increase in groundwater entering the model from storage (as groundwater levels fall), and less evapotranspiration, offshore discharge and baseflow to streams. Stream leakage into the modelled groundwater system is also reduced in the drier 2001-2022 period compared with the earlier period (by 20% in the Anglesea syncline and 24% in the Jan Juc syncline); baseflow to streams has fallen by larger proportions (40% and 38% respectively).

Transient variability in model water balance components (from which the averages discussed above are derived) are presented in Figure 6-37 and Figure 6-38, for the southern and northern synclines respectively. *An important point to note in these figures, and in all model groundwater level and stream flow hydrograph figures, is that there are periods of apparently greater variability in the late 1970's to early 1980's, and again in the late 2000's, than there is in intervening periods; readers are reminded that this is driven by coarser temporal model discretisation (as coarse as annual stress period durations) in the intervening periods, as is described in Section 4.4 and Figure 4-8.*

Figure 6-37 and Figure 6-38 show significant transient water balance variability within and across years, primarily depending on prevailing rainfall (recharge) conditions, but also, at least in the case of the Anglesea (southern) syncline, groundwater pumping and Alcoa mine void development. In contrast, in the Jan Juc (northern) syncline (Figure 6-38), there is very little anthropogenic influence on groundwater flux dynamics, aside from Barwon Water pumping from the LEVF for a brief period around 2012.

The Anglesea (Southern) Syncline

Focussing on the Anglesea (southern) syncline, Figure 6-39 presents modelled groundwater flux rates between the ASA and underlying UEVF, and Figure 6-40 presents that between the UEVF and underlying MEVF (hence also the underlying LEVF). Figure 6-44 and Figure 6-45 present corresponding data for the Jan Juc (northern) syncline.

Figure 6-39 shows that modelled groundwater flux between the ASA and UEVF is dominated by downward fluxes (from ASA to UEVF); this is true even in the initial steady state stress period, in which Alcoa operations did not exist, suggesting the root cause to be basin architecture and hydrogeology rather than Alcoa's historical activities[26]. Over the 50-year modelled period, upward leakage from the UEVF to the ASA has declined; similarly, rates of downward leakage from the ASA to the UEVF have declined, albeit less consistently or significantly than upward leakage has. Rates of downward leakage tend to increase markedly during wet (recharge and stream flow) events, as shown by the brief spikes in Figure 6-39; this is confirmed through Figure 6-41, particularly in the 2001-2022 period (bottom chart), which shows brief spikes in leakage from streams to groundwater (the ASA) corresponding with times when there are also spikes in downward leakage from the ASA to the underlying UEVF. In other words, recharge and stream leakage to the ASA during wet events raises watertable heads relative to the underlying UEVF, resulting in spikes in downward leakage from the ASA to the UEVF. Further confirmation of this is provided through the upper chart in Figure 6-42, which shows that for recharge events above 0.01 ML/day (to the ASA in the Anglesea syncline), there is increasing leakage down to the underlying UEVF; a similar albeit weaker correlation is also observed in Figure 6-42 with regard to stream flow versus ASA to UEVF leakage.

[26] Although this is not to say that Alcoa operations may not have altered this (what appears to be natural) process to some degree.

In terms of groundwater flux between the UEVF and LEVF (via the MEVF) in the southern (Anglesea syncline), Figure 6-40 shows generally upward leakage from the LEVF to the UEVF. At times of Barwon Water pumping from the LEVF (2010-2012, and again in 2020; periods of highest LEVF pumping in Figure 6-43), decreased upward leakage in conjunction with increased downward leakage are observed, as gradients are reduced and even locally reversed under pumping stress. One other subtle process is evident in Figure 6-40:

- A mild gradual increase in upward leakage from the LEVF to the UEVF from the late 1960s (pre-Alcoa mine) until the early 1990s (Figure 6-40); this may be a response to mine development and increasing UEVF depressurisation by Alcoa operations over this period, as shown in Figure 6-43. This is followed by a mild decrease in upward leakage as mine development slowed (Figure 6-40) and the UEVF had largely been depressurised in earlier times (Figure 6-43), in addition to a long-term trend of a drying climate post-1996.

The Jan Juc (Northern) Syncline

Focussing on the Jan Juc (northern) syncline, Figure 6-44 presents modelled groundwater flux rates between the ASA and underlying UEVF, and Figure 6-45 presents that between the UEVF and underlying MEVF (hence also the underlying LEVF).

Figure 6-44 shows that modelled groundwater flux between the ASA and UEVF is dominated by upward discharge into the ASA. There is generally very minor downward leakage to the UEVF, although there may be subtle evidence in Figure 6-44 of a slight increase over the Millennium Drought period (from the late 1990's), concomitant with declining upward leakage to the ASA. The converse is observed in the wet period of the mid-late 1970s, in which downward leakage suddenly decreased, and upward leakage increased. It is believed that this must be due to recharge to the ASA and UEVF in the northern syncline (or lack of it, as was the case in the Millennium Drought), rather than groundwater pumping, because:

- There was no groundwater pumping from the UEVF or LEVF in the northern syncline in the 1970's.
- The decline in upward leakage from the UEVF to the ASA during the Millennium Drought began and was occurring at the fastest rate before LEVF pumping by Barwon Water began (compare Figure 6-44 with Figure 6-46). Furthermore, there was no observed decline in rates of upward leakage to the ASA during the most intense period of Barwon Water LEVF abstraction in 2012.
- There is a seasonality in modelled rates of leakage between the ASA and UEVF aquifers (see the annual oscillations in the 1975-1982 and post-2007 periods in Figure 6-44; peaks are in late summer-autumn, whilst troughs are in late spring-early summer).

However, there is no strong correlation between ASA recharge with ASA to UEVF leakage, as shown in Figure 6-47 (top figure; measured across the entire Jan Juc syncline area). There is however strong evidence of this effect from UEVF recharge (both rainfall recharge, and recharge via stream leakage; Figure 6-47 bottom figure). This suggests that recharge to the UEVF plays a role in gradients that control flux rates from the UEVF up into the ASA aquifer.

Figure 6-45 shows that modelled groundwater flux between the UEVF and LEVF (via the MEVF) is generally upward, with brief periods of greater downward leakage when Barwon Water has historically operated its Northern borefield (primarily in the 2010-2012 period; see Figure 6-46). Trends in upward leakage from the LEVF to the UEVF weakly mirror those described above for ASA / UEVF leakage, and those for UEVF/LEVF leakage in the Anglesea (southern) syncline too. That is, a mild rise in upward leakage in the wet mid-late 1970s, followed by a mild to moderate decline over the Millennium Drought period (from the late 1990s onward), with a strong decline from the late 2000's. Rates of downward leakage from the UEVF to the LEVF have not changed markedly over the simulated period. The similarities in long-term temporal trends in upward leakage between aquifers and between synclines suggests that the primary driver is climatic (recharge).

6.1.9 Areas for Further Investigation

As is usual in the modelling process, several areas for further investigation and potential model improvement have been identified. None of these are considered critical to model reliability for impact assessment, particularly given that most model impact assessment is conducted in relative terms (i.e., as differences between scenarios).

Furthermore, given that this is a model of a very complex reality, as was outlined in the introduction to this report, some of these issues will likely never be fully resolved, because models are just that – imperfect, simplified representations of an infinitely complex reality, based on the understanding of the hydrologic system at the current point in time. It is for this reason that the developed modelling workflow documented in this report operates in a framework that recognises and accommodates these uncertainties and simplifications, and carries them through to forecast model outputs, and ultimately to reliant decision-making processes.

Most areas for further investigation that were identified in earlier modelling studies have been addressed and the model has been improved upon in many ways.

Whilst acknowledging the above points, identified areas for further investigation are outlined as follows:

- History matching to watertable depth variability in bore P9 appears hampered by model structure in some way; it may be that this bore screens a discrete relatively impermeable sub-unit of the ASA, because its behaviour differs quite markedly from all other watertable bores.
- If an improved model history matching is desired around the shallow (typically <10m bgl) Alcoa bores (located near the former Power Station), request EHS to revisit the model layers in this area (noting that heads in these bores are influenced by the largely poorly understood processes of historical water leakage from Alcoa site infrastructure). It is understood that modelling of groundwater behaviour in these bores were not of interest to EHS or Alcoa at the outset of the modelling process, and so this is unlikely to be required.
- Increase the history matching objective function weight of Alcoa pit water body levels, and potentially of AV1 gauged flows. Whilst the 263 model realisations cover the observed data, the base model realisation could potentially be improved in these regards.

7. Conclusion

An updated numerical groundwater flow model of the area around Barwon Water's Anglesea borefield and Alcoa's historical coal mine has been developed. The model is based in a minor sense on earlier modelling of GHD (2013) but is a wholly new model using a new numerical code, new layer structure, new parameterisation schemes, and modern methods of history-matching to historical observation data. It was built and operates in a stochastic framework that recognises input observation data and model parameter uncertainties.

The intent of using this approach is that the recognised input uncertainties are carried through to their effects on model forecasts and their uncertainty, and therefore their effects on water management decision-making.

The model simulates flux-conserved groundwater and surface water flow, and interactions between the two systems. It also simulates the post-Alcoa coal mine closure pit water body balance, including its interaction with groundwater and other surface water systems. The model history-matching process therefore uses a range of surface water and groundwater data of wide-ranging types, including pit water body water levels, to inform (constrain) model parameters. It also uses derivative observations such as watertable depth-frequency curves, flow-frequency curves, pumping-induced drawdown trends, and vertical hydraulic gradients.

The intent of employing these wide-ranging observation types is, to the extent possible, minimise related model forecast uncertainties, such as the uncertainty in potential effects from groundwater use on the shallow watertable (in swamps), surface water systems, and acid generation risks.

263 history matched model realisations, each with widely varying parameters, were derived from an initial (prior) ensemble of 500. For predictive scenario modelling purposes, a smaller, more manageable number of model realisations will be selected for application in that case (e.g., the top 150 models of higher history match quality).

History match quality across these models is generally very good, for groundwater levels in deeper bores, watertable depths in shallow bores, pit water body levels, and surface water flows. However, there are of course exceptions to this, which are discussed in Section 6. Selected points for further investigation and analysis - aimed at improving history-match quality at specific sites in specific ways - are identified and discussed in Section 6.1.9.

The model developed, and framework used, provide a sound basis for ongoing use of the model in the context of rigorous model forecast and uncertainty assessment for both Barwon Water's and Alcoa's unique requirements.

7.1 A note on intended model end use

Following Technical Review Panel (TRP) review of a draft of this report, questions were asked regarding further detail around how the history-matched models and modelling workflow developed are proposed to be used for risk assessment purposes by Alcoa and Barwon Water. Clarification of this is provided below.

The modelling workflow developed provides an ensemble of 263 history matched stochastic models (parameter sets) with which to conduct scenario simulations for risk assessment purposes. Those 263 stochastic parameter sets will be applied to each future potential development scenario that is simulated. As a precursor to this, for each of the key risk items outlined in Section 2, Quantities of Interest (QoIs) will be developed, which are model output metrics that can be used to assess the simulated level of risk. Barwon Water's risk assessment process has not yet been developed, because this is to be conducted under the BE process, which was not yet underway at the time of writing. For Alcoa's purposes however, draft QoIs have been developed and distributed to the TRP; see EHS, 2022b.

The modelling and uncertainty analysis workflow outlined in this report can be used to support a risk assessment for each of the specified QoIs. This will be conducted by posing the question: Is it considered likely, based on the 263 developed stochastic models (i.e., as assessed at the 95th percentile uncertainty estimate), that the QoI may be breached under a simulated potential future development scenario? That is, is there less than a 5% likelihood that the QoI may be breached? If so, then the risk of QoI breach, and in turn the unwanted outcome that the QoI is designed to be a proxy measure of, is considered low. If on the other hand there is a greater than 5% likelihood of this occurrence, then the modelling suggests that there is a material risk. Subject area specialists for each risk item will then translate that assessment of metrics into an assessment of risk in terms of acid generation and

ecological risk, for example. This approach forms an efficient means by which potential risk occurrence hypotheses can be tested. Whilst there are more rigorous forms of hypothesis testing available, these are computationally expensive[27], particularly given the range and number of QoIs that need to be assessed by Alcoa and Barwon Water – for each of which a computationally expensive pareto-type model assessment would need to be undertaken. If such an assessment were sought, then very simple, small, and computationally efficient models (note the plural) would need to be developed specific to each QoI; it is unclear how this could work in practice, given the spatial scale and wide breadth of risk types to be assessed in this case.

The TRP also specifically questioned "*whether the <PESTPP->IES methodology can or cannot rule out localised causal pathways between the <Alcoa mine> pit waterbody and ASA*". Clarification with the TRP revealed that "localised causal pathways" refers to pathways and/or mechanisms for connection between various aquifer/aquitard layers, and the potential to impact the ASA due to groundwater extraction from underlying layers. The spatially variable model parameterisation schemes used for almost all hydraulic properties and boundary conditions (via quite dense pilot points / 52,600 stochastically varying model parameters across each of the 263 stochastic models) is considered sufficiently detailed for assessment of these risks. Furthermore, the residual range of parameter uncertainty across the history-matched models is significant (see Section 6.1.7). It is also of note that there are as many as 11 model layers / sub-layers within and around the simulated Alcoa mine void; each of these is parameterised using the spatially dense pilot points, and hence there is not only significant simulated flexibility (uncertainty) in horizontal spatial variability, but also vertically, across those 11 layers. This is considered more detailed than most models, particularly when most of that vertical detail is in the shallow parts of the basin, within and directly below the simulated mine void elevation.

[27] to an impractical degree given model run times.

GW6
— LEVF
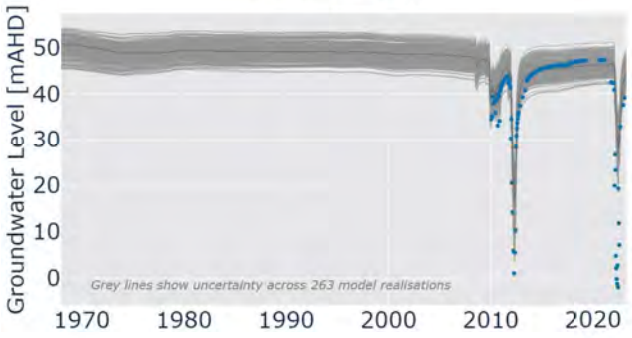
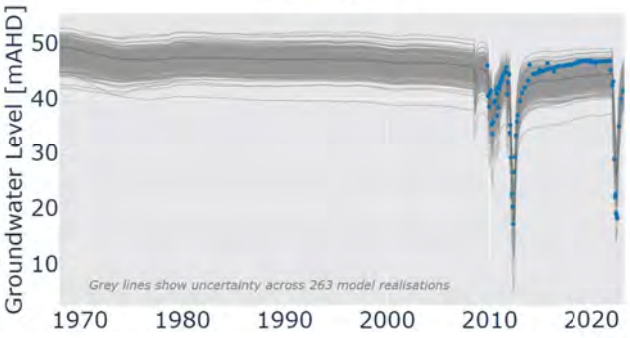
Screen from/to: 192.5m : 194.0m] (modelled historical)
GW6
• LEVF
Screen from/to: 192.5m : 194.0m] (observed historical)

GW7 (LEVF)



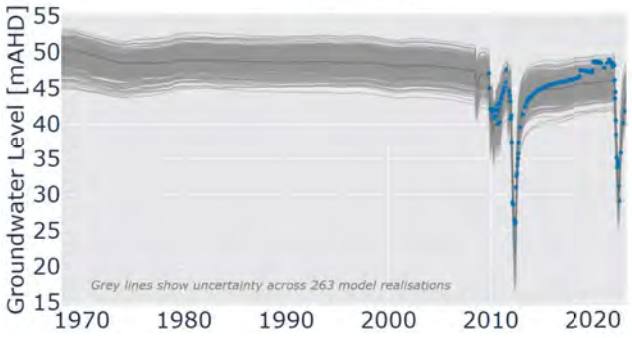
GW7
— LEVF
Screen from/to: 237.5m : 243.0m] (modelled historical)
GW7
▪ LEVF
Screen from/to: 237.5m : 243.0m] (observed historical)

NB1 (LEVF)



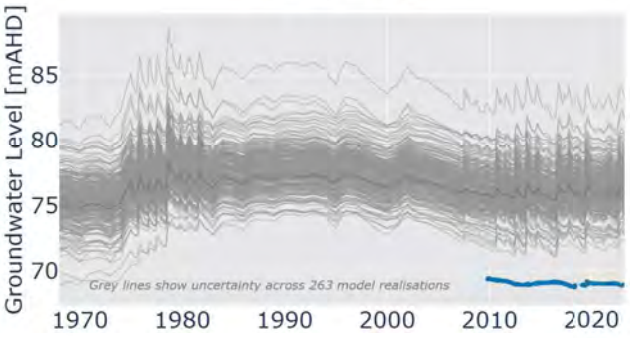
NB1
— LEVF
Screen from/to: 213.3m : 216.3m] (modelled historical)
NB1
▪ LEVF
Screen from/to: 213.3m : 216.3m] (observed historical)

P12 (LEVF)



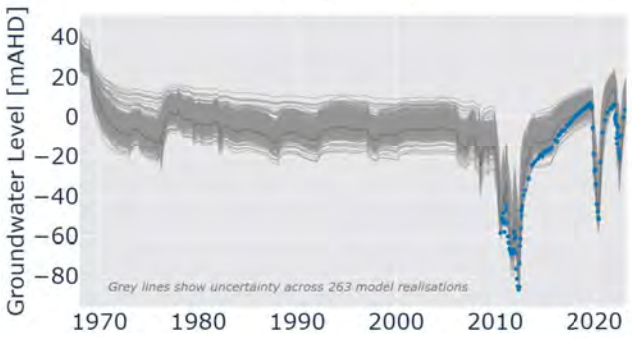
P12
— LEVF
Screen from/to: 40.0m : 43.0m] (modelled historical)
P12
▪ LEVF
Screen from/to: 40.0m : 43.0m] (observed historical)

P13 (LEVF)



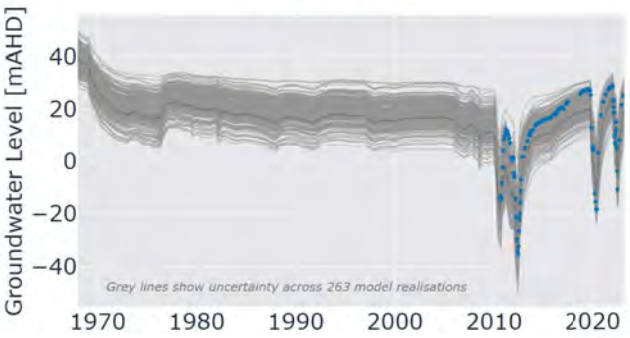
P13
— LEVF
Screen from/to: 36.0m : 39.0m] (modelled historical)
P13
▪ LEVF
Screen from/to: 36.0m : 39.0m] (observed historical)

P14 (LEVF)



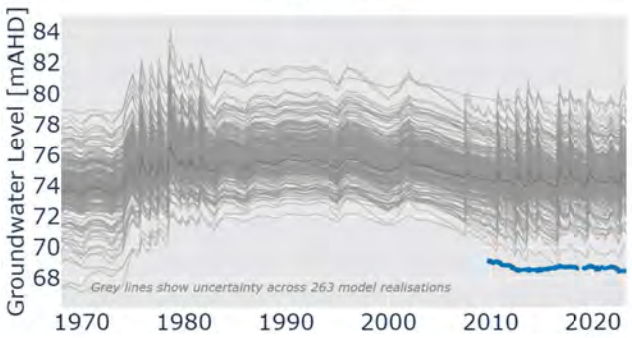
P14
— LEVF
Screen from/to: 394.1m : 396.1m] (modelled historical)
P14
▪ LEVF
Screen from/to: 394.1m : 396.1m] (observed historical)

P15 (LEVF)



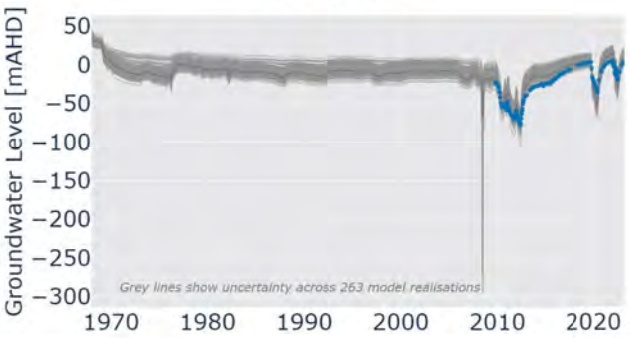
P15
— LEVF
Screen from/to: 362.9m : 363.9m] (modelled historical)
P15
▪ LEVF
Screen from/to: 362.9m : 363.9m] (observed historical)

P3 (LEVF)



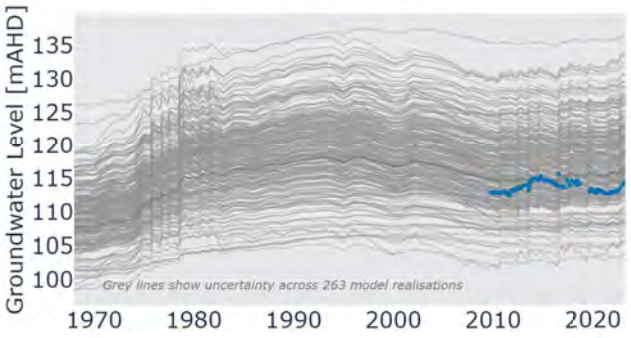
P3
— LEVF
Screen from/to: 25.0m : 31.0m] (modelled historical)
P3
▪ LEVF
Screen from/to: 25.0m : 31.0m] (observed historical)

SB1 (LEVF)



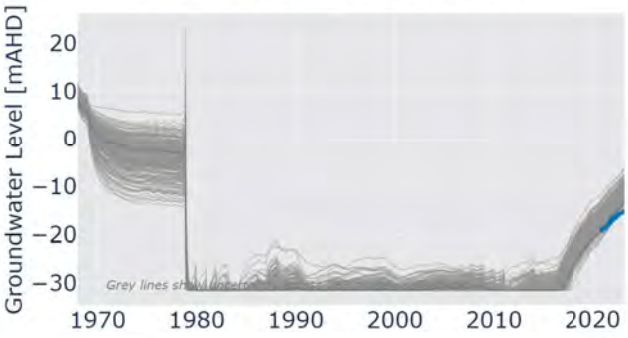
SB1
— LEVF
Screen from/to: 266.1m : 268.1m] (modelled historical)
SB1
▪ LEVF
Screen from/to: 266.1m : 268.1m] (observed historical)

WTOB5 (LEVF)



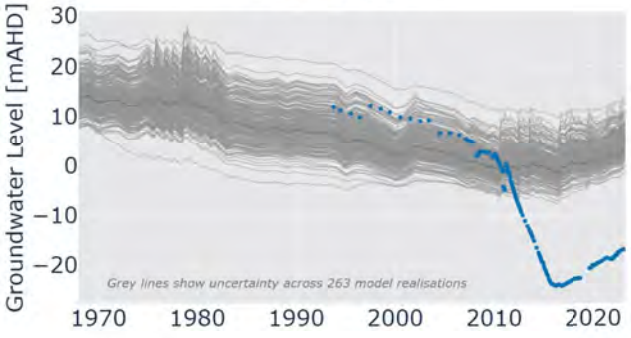
WTOB5
— LEVF
Screen from/to: 1.1m : 7.1m] (modelled historical)
WTOB5
▪ LEVF
Screen from/to: 1.1m : 7.1m] (observed historical)

DBG MB6 (Mine Overburden)



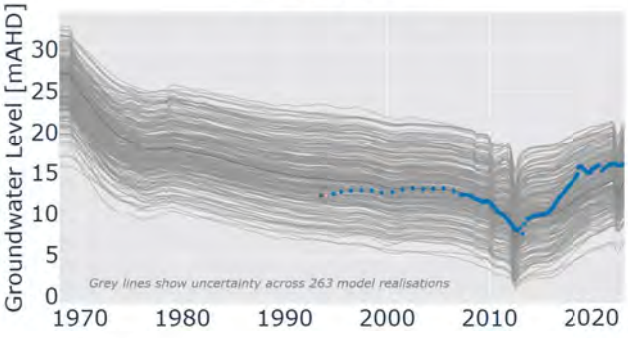
DBG MB6
— Mine Overburden
Screen from/to: 34.0m : 37.0m] (modelled historical)
DBG MB6
▪ Mine Overburden
Screen from/to: 34.0m : 37.0m] (observed historical)

115868 (UEVF)



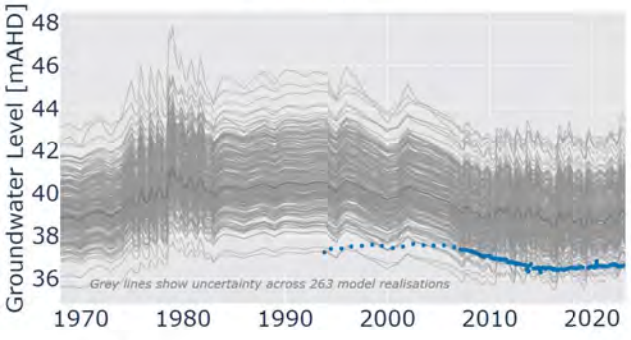
115868
— UEVF
Screen from/to: 178.0m : 184.0m] (modelled historical)
115868
▪ UEVF
Screen from/to: 178.0m : 184.0m] (observed historical)

115869 (UEVF)



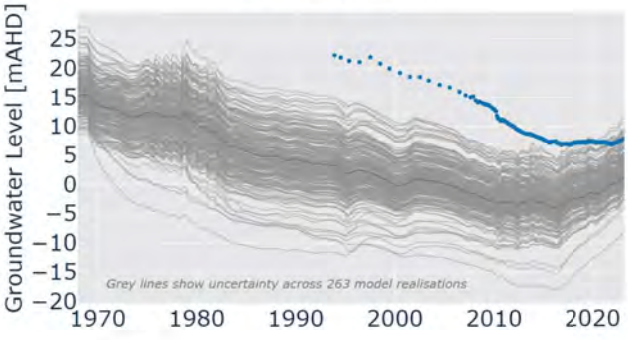
115869
— UEVF
Screen from/to: 127.0m : 130.0m] (modelled historical)
115869
▪ UEVF
Screen from/to: 127.0m : 130.0m] (observed historical)

116458 (UEVF)



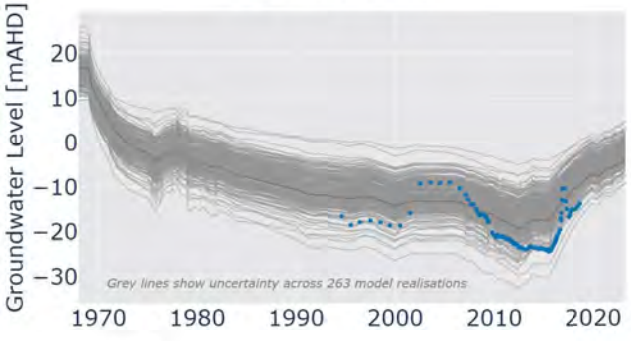
116458
— UEVF
Screen from/to: 100.0m : 112.0m] (modelled historical)
116458
▪ UEVF
Screen from/to: 100.0m : 112.0m] (observed historical)

116459 (UEVF)



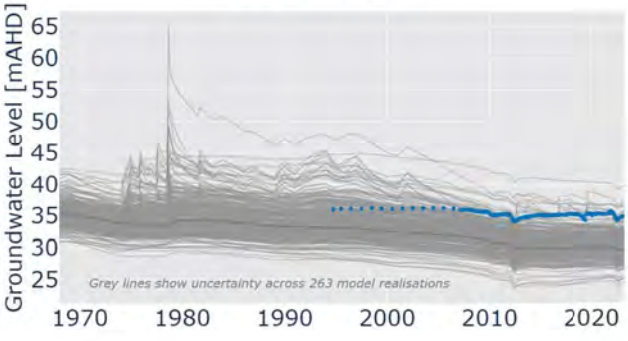
116459
— UEVF
Screen from/to: 243.0m : 246.0m] (modelled historical)
116459
▪ UEVF
Screen from/to: 243.0m : 246.0m] (observed historical)

119349 (UEVF)



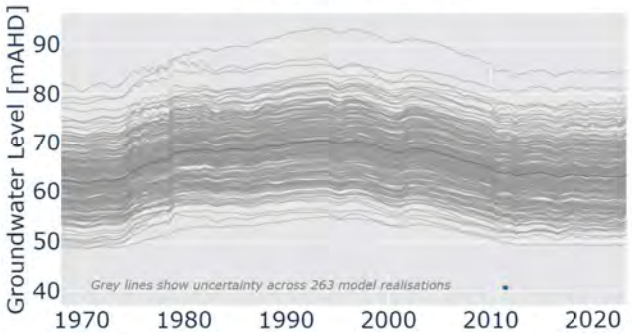
119349
— UEVF
Screen from/to: 183.0m : 186.0m] (modelled historical)
119349
▪ UEVF
Screen from/to: 183.0m : 186.0m] (observed historical)

121768 (UEVF)



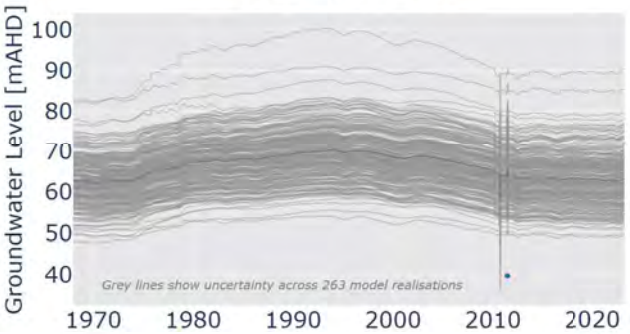
121768
— UEVF
Screen from/to: 100.7m : 108.0m] (modelled historical)
121768
▪ UEVF
Screen from/to: 100.7m : 108.0m] (observed historical)

ASR_OB1 (UEVF)



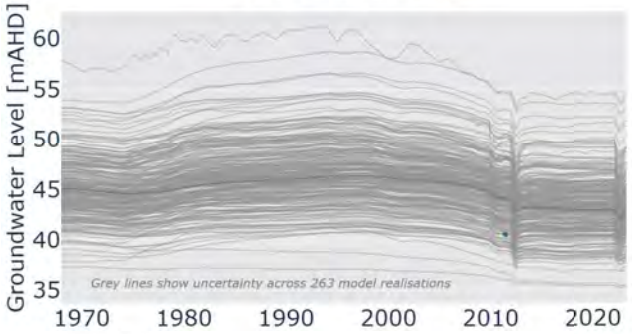
ASR_OB1
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB1
▪ UEVF
Screen from/to: n/a : n/a (observed historical)

ASR_OB2 (UEVF)



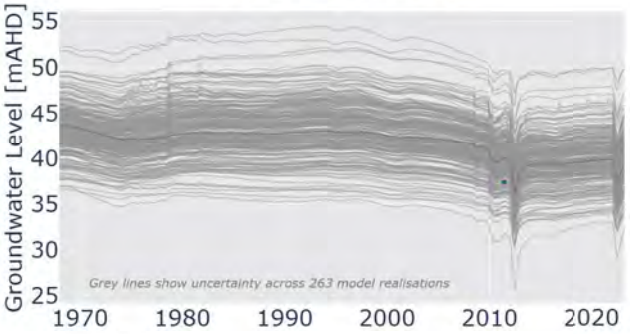
ASR_OB2
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB2
▪ UEVF
Screen from/to: n/a : n/a (observed historical)

ASR_OB3 (UEVF)



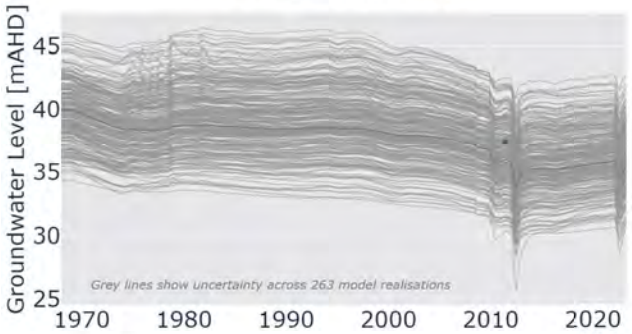
ASR_OB3
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB3
▪ UEVF
Screen from/to: n/a : n/a (observed historical)

ASR_OB4 (UEVF)



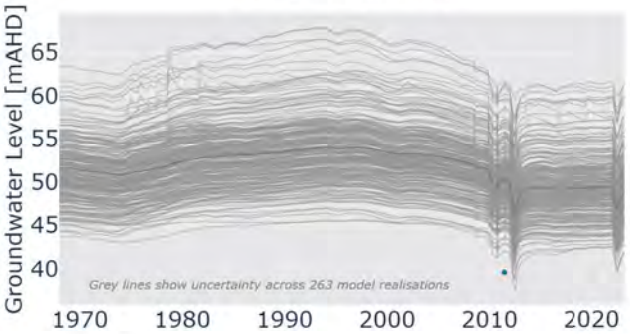
ASR_OB4
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB4
▪ UEVF
Screen from/to: n/a : n/a (observed historical)

ASR_OB5 (UEVF)



ASR_OB5
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB5
▪ UEVF
Screen from/to: n/a : n/a (observed historical)

ASR_OB6 (UEVF)



ASR_OB6
— UEVF
Screen from/to: n/a : n/a (modelled historical)
ASR_OB6

Observation Bore Integrity Memo

Technical Memorandum

02 March 2023

To	Barwon Water	**Contact No.**	0427700781
Copy to		**Email**	jeffrey.morgan@ghd.com
From	Jeff Morgan	**Project No.**	12542999
Project Name	Anglesea Borefield: Groundwater Model Update		
Subject	Observation Bore Integrity		

1. Introduction

There are several Government observation bores in the Anglesea area that were constructed in the early-mid 1990's. These are currently monitored, however the integrity of these bores, and therefore the monitored groundwater level data, is questionable. Most of these bores have been used for history matching in the recent model update completed (GHD, 2022) and the integrity of two bores (116459 and 115868) was specifically questioned.

The purpose of this memo is to highlight the older State Observation Bore Network (SOBN) bores that appear to have integrity issues, and the reasoning behind this conclusion. This additional detailed information is planned to be included in the report as an additional appendix to add clarity to this issue, and can be further considered in future model history matching which is planned in 2023 and clarify these potential issues for the TRP.

The monitoring bore network in the Anglesea area is shown in Figure 1

This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

2. Nested Bores- 116459 (UEVF) and 115867 (LEVF)

These nested bores are located on Bald Hills Rd to the west of Alcoa's pit (refer Figure 1). These two bores are part of the SOBN and were drilled by Hydrotechnology in 1994 as part of a groundwater investigation program in the Torquay Basin.

The bore construction is summarised in Table 1 below and the long term hydrographs of these two bores, and a third adjacent bore 122149 (LEVF) is shown in Figure 2 (1993-2022), and the shorter term hydrograph (2009-2022) shown in Figure 3.

Table 1 State Observation Bore 116459 and 115867 details

Bore ID	Aquifer	Drilled Date	Drilled Depth (m)	Screen From (m)	Screen To (m)	Notes
115867	LEVF	1992	495.7	359	362	DELWP consider failed based on camera inspection DELWP No long monitor this bore Barwon Water do monitor the bore

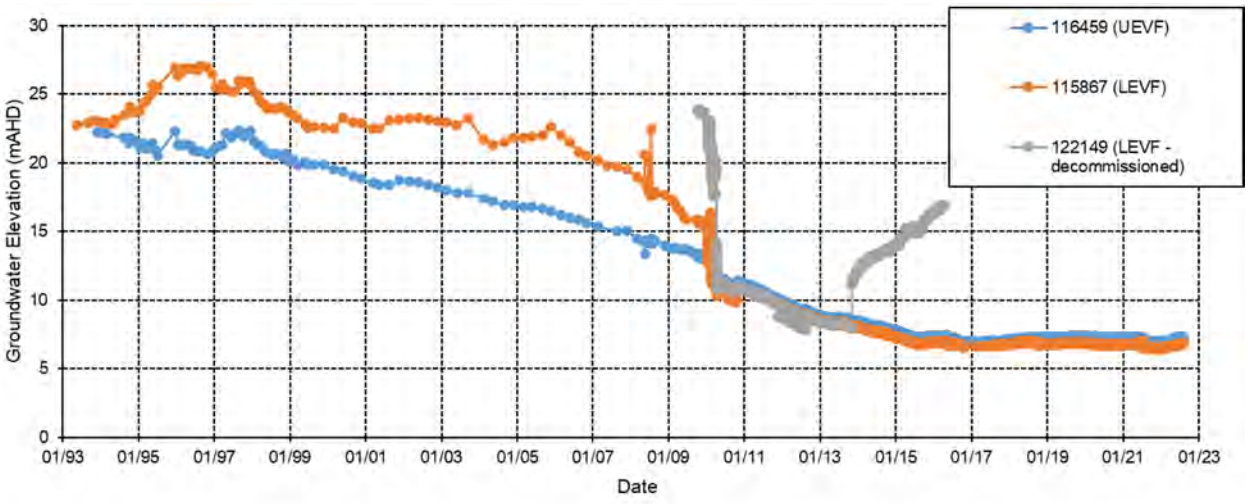
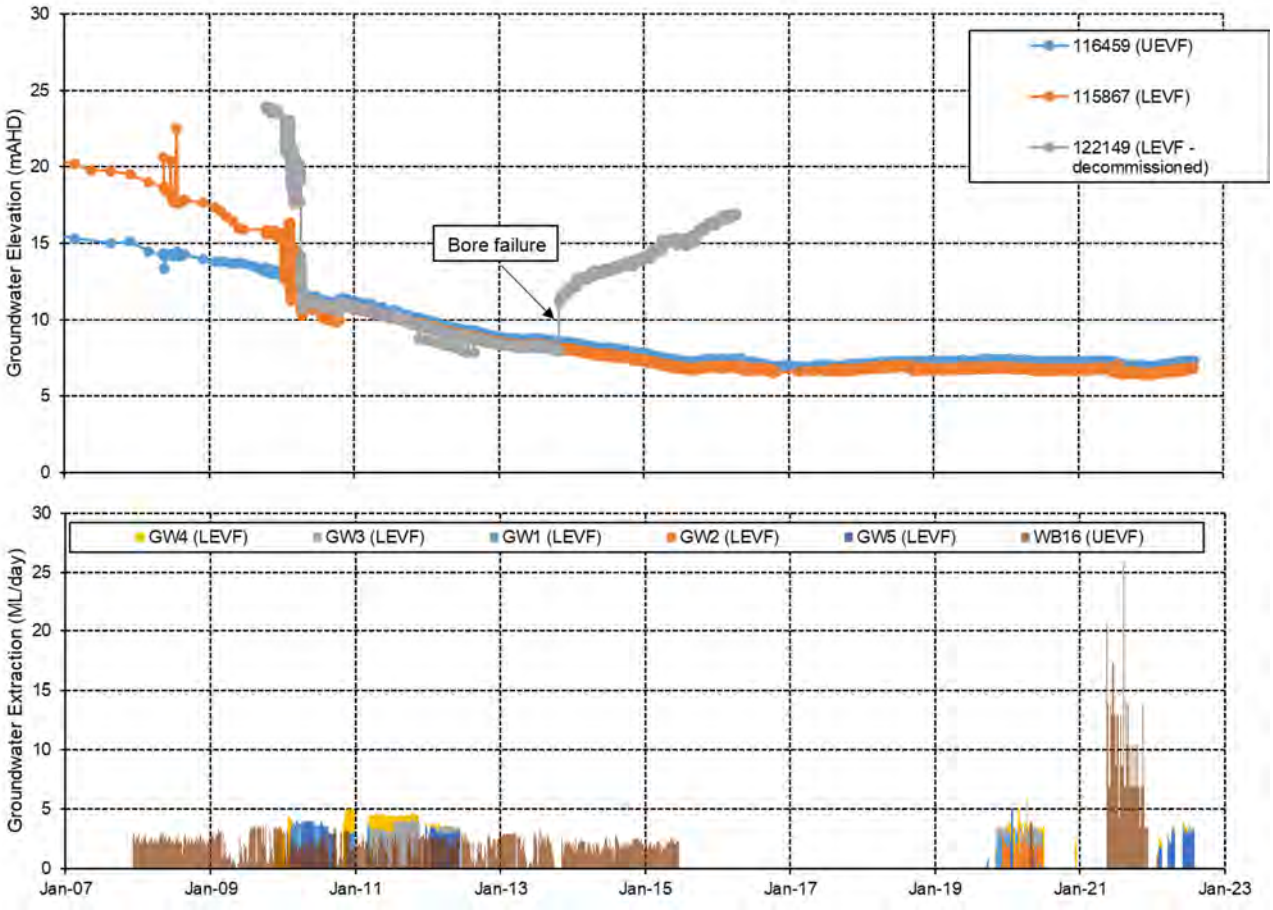
122149	LEVF	1992	383	349	383	Decommissioned in 2015/16

Figure 2 Long term Hydrograph 115867 (LEVF), 116459 (UEVF), 122149 (UEVF)



This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

Figure 3 Hydrograph 115867 (LEVF), 116459 (UEVF), 122149 (UEVF) 2009-2022



When 116459 (UEVF) was first drilled the bore was artesian with a head of +3.3m above ground level (mAGL) recorded, and the 115867 (LEVF) was also artesian +0.42mAGL. As can be seen in the hydrograph the LEVF head was generally higher than the UEVF head by around 2-4m pre 2009 (i.e., an upward vertical hydraulic gradient). Groundwater levels in both bores are generally declining since around 1998.

In 2009/2010, when Barwon Water started extraction from the LEVF, the groundwater levels in 115867 (LEVF) and 122149 (LEVF) initially declines, but then as can be seen in Figure 3, the potentiometric head in all three bores stabilised around the same level. This response is indicative of at least one bore failure, with either a hole in the casing or an issue with the grout seal around the casing, and inter-aquifer flow is now occurring around these nested bores.

The heads in these bores remained similar unit 2013 when a sudden head recovery of around 3m occurred in 122149 (LEVF). This sudden change again may indicate a failure of the bore casing or an associated seal, or alternatively a pathway of inter-aquifer flow was closed off. Subsequently DELWP completed a bore condition assessment and confirmed the bore casing was in poor condition, the bore was blocked and was likely to have failed. Bore 122149 was decommissioned by DELWP in 2016.

It is also noted that many of the SOBN bores in the area were not constructed to today's standards, with the seals between aquifers generally being short grout plugs, rather than full pressure grouting which is required to ensure an effective long-term seal between aquifer systems.

The potential inter-aquifer connection at this Salt Creek site has been noted in many previous reports (including GHD, 2013- the last BE review). Since 2009, the remaining two bores 116459 and 115867 continue to mirror each other; the **groundwater level in both bores is likely compromised and the reliability of the data is questionable.** Since Alcoa has reduced and then ceased large scale extraction in

This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

late 2015 / early 2016, both these observation bores have recorded a slow increase in groundwater levels. Interestingly, when Alcoa completed a 6-month pumping test on UEVF production bore WB16 from May 2021 to December 2021, groundwater levels at 115867 (LEVF) and 116459 (UEVF) were both relatively stable throughout the Alcoa extraction period, although they appear to show a slight drawdown/stabilisation response between June 2021 and August 2021 when extraction rates at WB16 were at their highest. There was no distinct response in either of these bores to the end of Alcoa's UEVF extraction or Barwon Water's changes in extraction from the LEVF over the period of January to July 2022. Over the last few months there appears to be a slight recovery trend that starts around a month after Alcoa extraction ceases. This recovery trend does not seem to be impacted by the LEVF extraction.

Following a camera inspection in 2019, DELWP concluded that 115867 (LEVF) had failed and ceased monitoring the bore, whilst Barwon Water has continued to monitor the bore despite the bore reliability being questionable, as it is in a key location being just west of the mine pit.

DELWP refurbished bore 116459 (UEVF) in 2019, however if the adjacent LEVF bore is a pathway for inter aquifer flow then the water level in this bore will also still likely be compromised.

In conclusion, the potentiometric head in both 116459(UEVF) and 115867 (LEVF) appear to be impacted by inter aquifer flow possibly due to bore failure or poor inter aquifer seals. It is possible (even considered likely) that the drawdown response in 116459 (UEVF) has been dampened or reduced due to leakage from the LEVF aquifer around these nested bores. Similarly, the drawdown and recovery response in 115867 (LEVF) during Barwon Water extraction in 2012 and 2022 was probably restricted by inter aquifer leakage in this area. The true magnitude of drawdown or leakage impacts are not known.

It is obvious that these nested bores stopped being reliable post-2009, but the data pre-2009 may have also been influenced by inter aquifer leakage, albeit to a lesser degree and not to such an obvious degree**.**

3. Bore 115868 (UEVF)

Bore 115868 (UEVF) is loosely nested with bore P15 (LEVF), and located to the south west of the mine void and west of the Barwon Water's Anglesea borefield (Figure 1). Bore 115868 was drilled in the early 1990's as was part of the SOBN, while P15 was installed by Barwon Water in 2009.

The bore construction is summarised in Table 2 below. Long-term hydrographs of these two bores are shown in Figure 2 and the shorter-term hydrographs (2007-2022) are shown in Figure 3.

Table 2 115868 and P15 Details

Bore ID	Aquifer	Drilled Date	Drilled Depth (m)	Screen From (m)	Screen To (m)	Notes
115868	UEVF	1992	245.4	178	184	1 x 6m screen DELWP consider that bore is possible blocked. DELWP No long monitor this bore. Barwon Water do monitor the bore
P15	LEVF	2010	530	362.9	460.4	5 screens through the LEVF

This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

Figure 4 Long term Hydrograph 115868 (UEVF), P15 (LEVF)

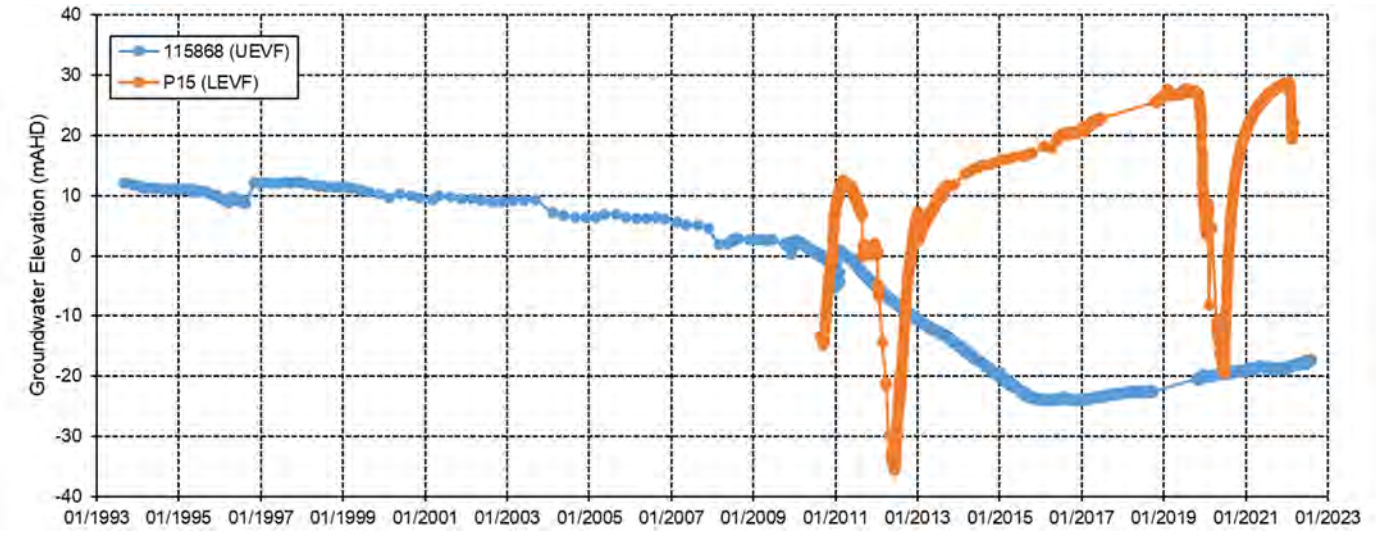


Figure 5 Hydrograph 115868 (UEVF) and P15 (LEVF) 2007-2022

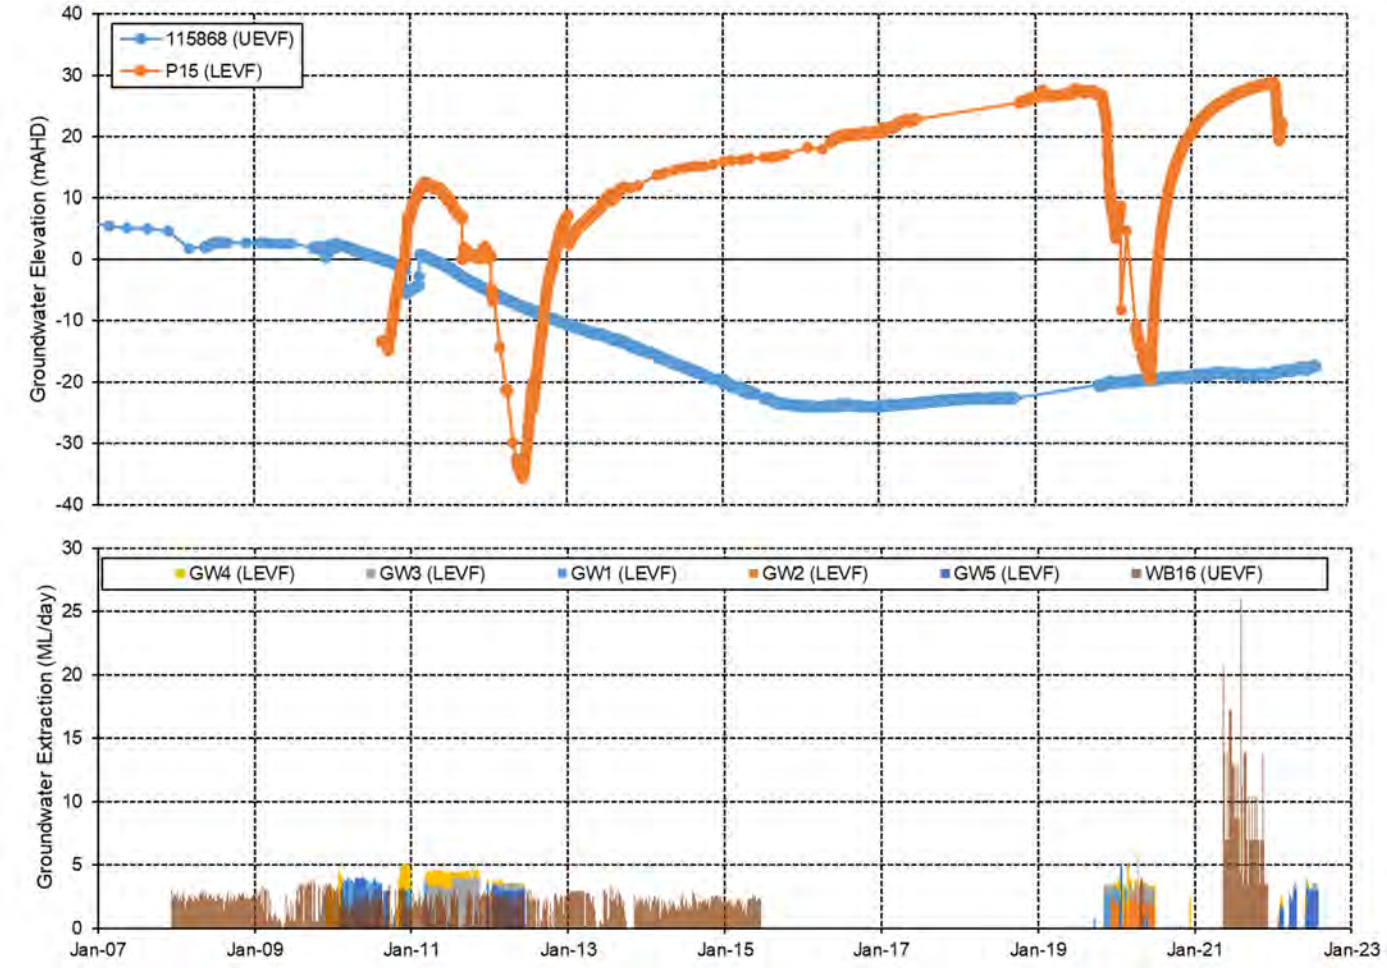


This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

When 115868 (UEVF) was first drilled the groundwater depth was 71.8 m below ground level (11 mAHD). From 1993 to 2007 the groundwater level in the bore gradually declined by around 10 m. In early 2010, around the time Barwon Water started testing their LEVF extraction bores, the groundwater level in this UEVF bore started to decline rapidly. From 2010 to 2016 the groundwater level in this bore declined around 25m. The declining trend did not cease or return to the pre-2009 rate, even when LEVF extraction was ceased in 2012. In fact, there was no response in this UEVF bore, apart from the start point in 2010; this suggests that the sudden decline was related to LEVF extraction. The groundwater levels in the bore started to stabilise in late 2015, corresponding with a decline and eventual ceasing of large scale UEVF extraction by Alcoa. Since then, groundwater levels have slowly recovered, with a similar pattern to 116459, located around 2.5km to the north-west (refer Figure 6). The recovery tend was temporarily stabilised in 2021 when Alcoa did the test pumping on WB16, and has now continued.

The decline in bore 115868 (UEVF) was approximately 31m in comparison to 116459 (UEVF) which declined around 10m, and which is closer to Alcoa's extraction bores (from 2006 to 2015) and mine void groundwater sink, as summarised in Table 3 (keeping in mind as noted above 116459 itself has integrity issues).

Table 3 Changes in Groundwater heads between Bore 116459 (UEVF) and 115868 (LEVF) between 2006 and 2015

Bore	Approximate Distance from Alcoa extraction bores (Kms)	Approximate Potentiometric level (m RL) in 2006	Approximate Potentiometric level (m RL) in 2015 (1)	Approximate water level Decline (m) between 2006 and 2015	Comment
116459 (UEVF)	2.5	17	7	10	Has integrity issues (as noted in Section 2)
115868 (UEVF)	4.5	6	-24	31	Further from Alcoa production bores so no reason why drawdown should have exceeded 116459
Head difference between 2 bores		9	31		

Notes (1) Prior to Alcoa Ceasing extraction

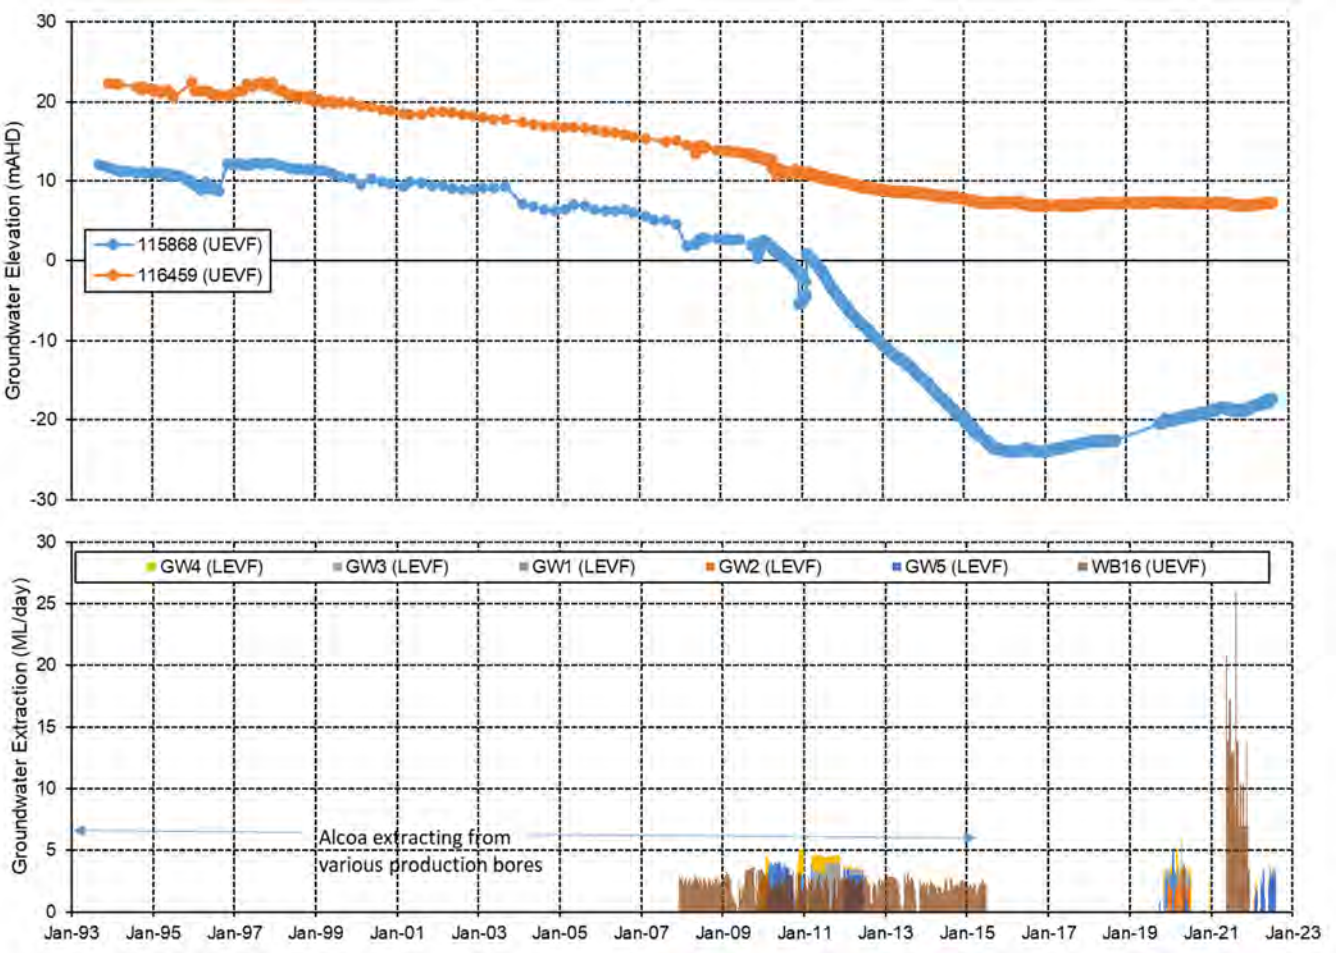
It is concluded that UEVF bore 15868 also has integrity issues and groundwater heads many be unreliable, based on the following reasons:

- Water levels in the bore suddenly declined from 2010 to 2016 for no logical reason.
- The water level decline is much greater than that at bore 116459 (closer to the pit and other groundwater stresses).
- The bore is considered blocked by DELWP**.**

GHD postulates that the LEVF extraction in 2010, for some unknown reason (pressure changes?), caused clearing of a screen blockage and allowed reconnection with the UEVF aquifer (or the one sand layer screened). Subsequently the bore may have monitored the UEVF to some degree/level since 2010, but it appears to be compromised given its conspicuously low head relative to other bores located closer to centres of UEVF stress (the Alcoa mine and pumping bores). The large decline in groundwater level noted since 2010 in this bore could potentially also be influenced by the individual sand zone screened, but this is unclear. If. This potential issue is relevant for most of the SOBN bores, whilst the newer monitoring bores normally screen numerous sand layers, like the production bores do, and therefore provide more representative results of groundwater levels with the aquifer system as a whole.

This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

Figure 6 Long term Hydrograph 115868 (UEVF) and 116459 (UEVF)



4. Other Observation bores

For completeness, some additional commentary in regard to bore integrity and bore responses has been included (which has been documented in other reports and memos).

– **UEVF southern syncline**

Alcoa observation bores monitoring the UEVF, WB4, WB5, WB12, WB14 and WB15 (Figure 1) show a minor but distinct response to Barwon Water extraction from the LEVF aquifer prior to July 2020. This response had been discussed with Alcoa, and was a subject of review (GHD, June 2020), where inter-aquifer connection was concluded to likely be related to a number of Alcoa bores which intersected the MEVF aquitard (i.e., WB9, WB10). A number of these Alcoa bores have since been decommissioned by Alcoa (WB5, WB9, WB10, WB13, WB17) to attempt to minimise interaction. The historical groundwater levels may be impacted to some degree from this potential inter aquifer flow (noting that some bores like WB9 have been assigned screens in both aquifers in the model).

– **SOBN bores**

DELWP have refurbished the following SOBN bores over the last few years:

- 116460 (LEVF): 2019
- 119347 (LEVF): 2020
- 116459 (UEVF): 2019

This Technical Memorandum is provided as an interim output under our agreement with Barwon Water. It is provided to foster discussion in relation to technical matters associated with the project and should not be relied upon in any way.

- 119348 (LEVF):2019

As noted previously, in general it was considered by GHD and DELWP that many of these bores were poorly constructed and may have allowed inter aquifer flow, and therefore the reliability of the historical record could be questionable.

– **Bore 121768 (UEVF)**

This bore is screened across two intervals between 100.7 to 120.8. The bore is located on the Bells Beach anticline, the bedrock high between the northern and southern Barwon Water borefields. Hydrotechnology, 1992 concluded that the sand screened was UEVF based on core and palynological analysis. Bedrock was intersected at 122.5m (i.e., no LEVF is present over the anticline).

Despite screening the UEVF there was a distinct recovery trend in this bore in 2012 following Barwon Water's 6-month extraction test from the LEVF. Similarly, a decline in groundwater levels in this bore was noted in mid-2022, while Barwon Water were undertaking their latest extraction test, indicating that extraction from the LEVF is having some effect on groundwater levels in the UEVF in the area of the anticline.

It is hypothesised that on the flanks of the anticline the sediments are thinner (including the MEVF aquitard), possibly inter-layered and the UEVF and LEVF aquifers potentially become more hydraulically connected in this area, causing the response observed.

Appendix G Quarterly Reporting Template

Mine Groundwater Monitoring

QUARTERLY UPDATE NOVEMBER 2024

This quarterly update provides a status of groundwater levels for key monitoring bores, including any groundwater extraction from the Upper Eastern View Formation (UEVF) aquifer, for the Anglesea Mine.

Note that the groundwater pumping test commenced on 13 May 2021, and was completed on 8 December 2021. No groundwater has been extracted since.

In summary:

- This report provides the quarterly update based on the November groundwater monitoring event data collection on 14 November 2024.
- No water was extracted during this period and total rainfall for the three-month period 12 August to 14 November was 147.4 mm. Note that rainfall in the previous quarter 8 May to 12 August was 123.6 mm.
- As of 10 October 2024, the water level was RL -15.40 which represents approx. 19.3% of the proposed full volume of the waterbody. (Relative level, or RL, is the water level in metres below sea level.).
- No water has been extracted since 8 December 2021, and the groundwater level in the lower part of the UEVF has returned to its pre-test level. Refer to Graph 1.
- There is no change to groundwater level behaviour in the upper part of the UEVF aquifer which is gradually increasing (refer Graph 2), or the unconfined shallow Demons Bluff Group (DBG) and Perched Water Table (PWT) aquifers which are responding to natural climate variations (refer Graph 3).
- Groundwater levels at unconfined shallow wells MW33 and MW64 have showed a steady decline due to lower-than-average rainfall recorded in the region from November 2022 to August 2024.
- Water quality observations of note:
    - General mine water body quality is stable and consistent with historical events.
    - pH is decreasing at DBG MB6. Figure 27 suggests groundwater at this location is has not reached an equilibrium. At this location, the current direction of groundwater flow is towards the mine water body.
    - TDS is increasing at DBG MB4. This appears to be driven by an increase in chloride (Figure 28). At this location, the current direction of groundwater flow is towards the mine water body.
- Note: Following the November 2022 groundwater monitoring event, two data loggers were identified to be replaced (WB4 and MW37). Following deployment of these dataloggers, all datalogger reference points were updated following the groundwater monitoring event (GME). This highlighted that some dataloggers exhibited “data drift”. As a result, following the February 2023 GME, all data was referenced against manual gauging data and where required (namely UEVF MB 1, 2, 4 and 6), data was normalised to correct data drift.
- The data logger in UEVF MB2 failed and was replaced on the 21 November 2023. Following deployment of the new datalogger, a new reference point has been established.

- The datalogger in DBG MB04 failed and was replaced on the 9 May 2024. Datalogger data is not available for the period 20 February to 8 May 2024.
- The datalogger in WB12 and WB14 could not be downloaded on the 13 August 2024. Datalogger data is not available for the period 8 May 2024 to 14 November 2024. The dataloggers in these two bores were replaced on 14 November 2024.
- From November to December 2022 groundwater levels at SOBN 116459 declined, which coincided when Barwon Water were undertaking a pumping test from the LEVF. Groundwater levels have increased by approximately 2.0 m since the cessation of the Barwon Water pumping test.

Background

The groundwater pumping test commenced on 13 May 2021 and was completed on 8 December 2021.

The test was run in accordance with the licence.

A total of 671.9ML was extracted during the pumping test, representing approximately 44% of the licensed volume.

Specialist consultants are now collating, analysing and validating the data collected during stage one to determine a sustainable pumping rate.

Monthly reviews were conducted with the Co-regulator Technical Working Group (inclusive of Alcoa, Southern Rural Water, DELWP, EPA Victoria, Earth Resources Regulation, Barwon Water and Corangamite Catchment Management Authority).

The data will also facilitate the calibration of the updated 'Anglesea Groundwater Model' being developed in close conjunction with Barwon Water. The model is being independently peer reviewed by a Technical Review Panel established by DELWP and will further inform any proposed long-term licence amendment.

The groundwater pumping test was underpinned by a comprehensive water monitoring plan approved by Southern Rural Water. The plan ensured the groundwater extraction did not threaten groundwater dependent ecosystems that may connect to the aquifer underlying and surrounding the mine, or adversely impact any other users.

Water extraction rates, groundwater levels and quality, and the waterbody level were closely monitored by a specialist consultant. Results were reported monthly to the co-regulator technical working group (inclusive of Alcoa, Southern Rural Water, Department Environment Land Water and Planning, EPA Victoria, Earth Resources Regulation, Barwon Water and CCMA) for review, and an update published for the community.

To monitor groundwater levels and quality during the pumping test, 28 bores have been selected with 12 of those also nominated as trigger bores. The location of the trigger and other monitoring bores are shown in Figure 1 below.

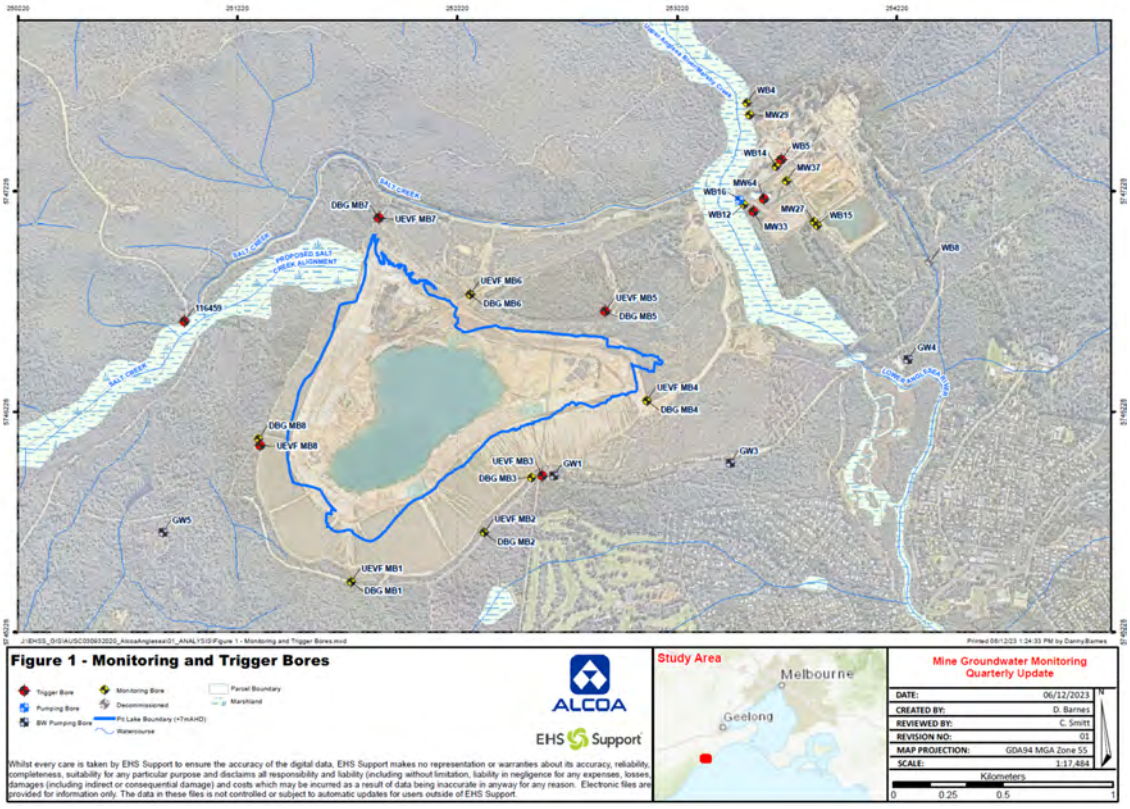

Figure 1: *Trigger and other monitoring bore locations.*

Each of the trigger bores has defined water level and/or water quality thresholds, known as triggers, and defined response actions if a trigger is met. The triggers and responses, known as trigger rules, were developed in consultation with a specialist consultant and Southern Rural Water.

Each trigger has been set at a conservatively low level to ensure we are alerted early, and, if necessary, able to act quickly during the pumping test to prevent damage to groundwater dependent ecosystems. In total there are five separate trigger rules, with these applying in various combinations to the 12 trigger bores. Each trigger rule has different responses ranging from additional monitoring to reducing the pumping rate.

Data from key Barwon Water monitoring bores in the vicinity is also included in the water monitoring plan for analysis. This data is provided by Barwon Water.

Extraction rates

Month	Volume extracted (ML)	Maximum daily volume extracted (ML)	Total volume extracted to date (ML)
May 2021 (from 13/5)	53.6 ML	3.45ML	53.6 ML

			September 2024	66.8	54.9
8 October 2024	-15.40	19.3%*	October 2024	48.8	48.8
			November	21.6	19.9

*Total estimated volume of the water body is 17,600ML (17.6GL) at RL 5.0m (based on latest bathymetry survey from Berry and Whyte, June 2024).

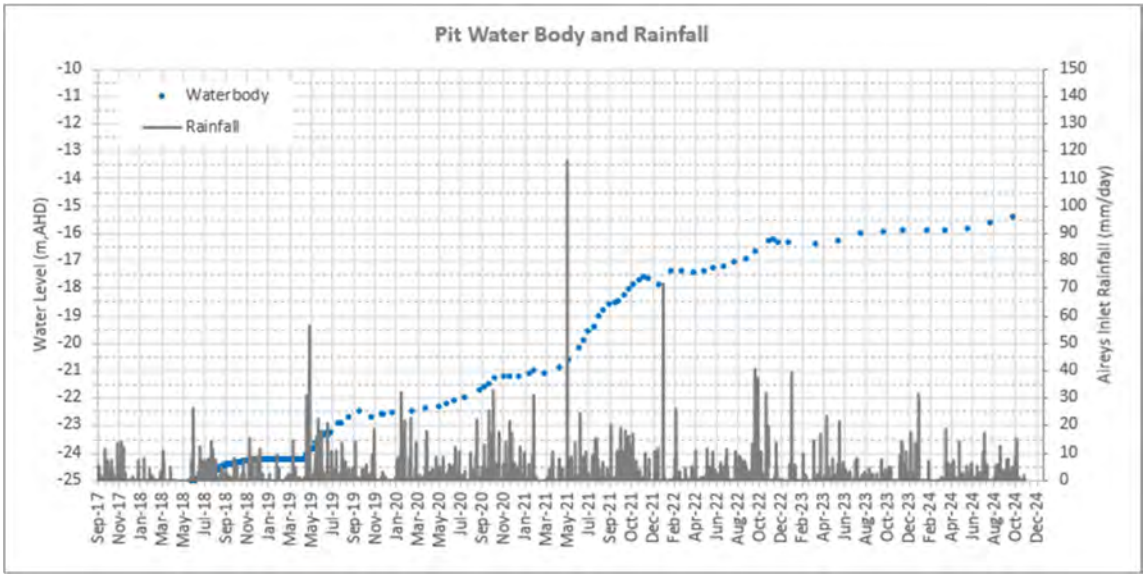

Figure 3: Pit waterbody level and rainfall

Groundwater level monitoring and trigger status

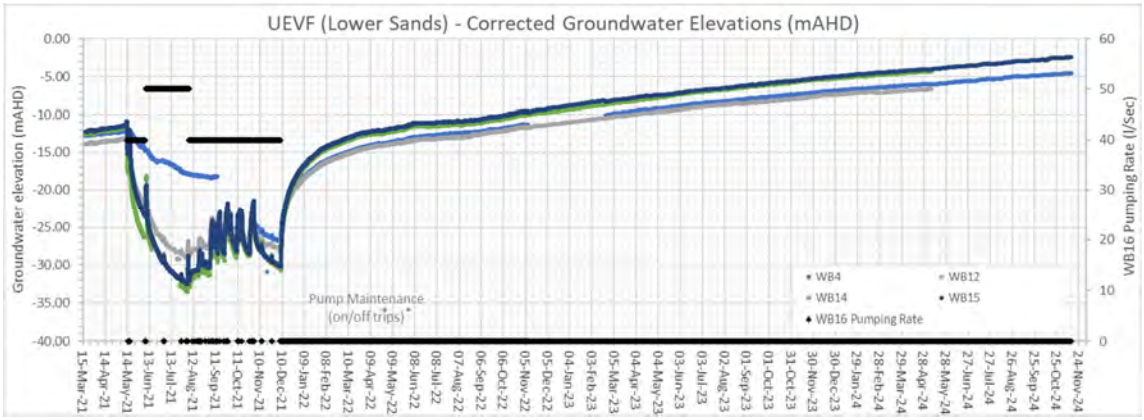
Although Alcoa did not pump during this reporting period, we continue to monitor the bores quarterly.

Bore	Overall status	Action / Comment
UEVF WB14	No trigger reached	Continue to monitor
UEVF SOB 116459	No trigger reached	Continue to monitor
UEVF MB3	No trigger reached	Continue to monitor
UEVF MB5	No trigger reached	Continue to monitor
UEVF MB7	No trigger reached	Continue to monitor
UEVF MB8	No trigger reached	Continue to monitor
DBG MB3	No trigger reached	Continue to monitor
DBG MB5	No trigger reached	Continue to monitor
DBG MB7	No trigger reached	Continue to monitor
DBG MB8	No trigger reached	Continue to monitor
PWT MW33	No trigger reached	Continue to monitor
PWT MW64	No trigger reached	Continue to monitor

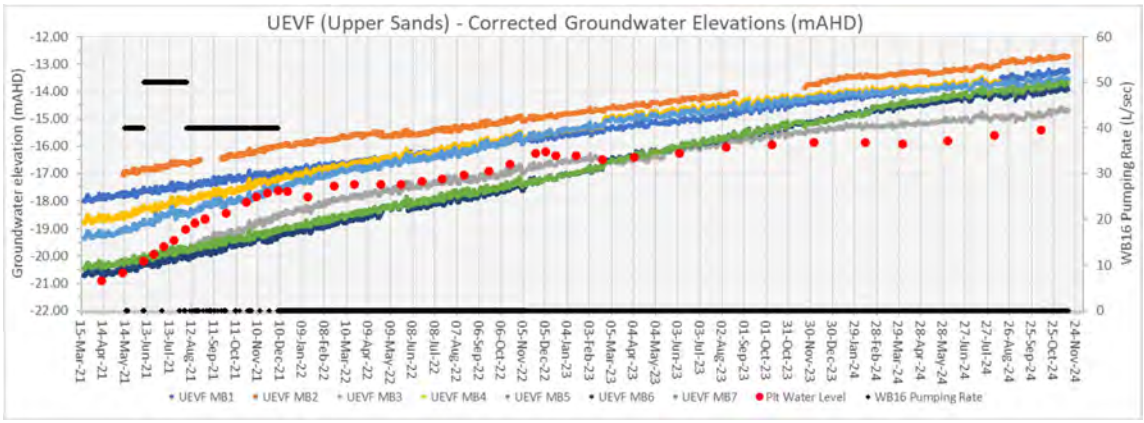
Current Key Data

Below (page 9) are graphical representations of some of the key data since stage one of the pumping test concluded on 8 December 2021.

- Graph 1 shows that the groundwater levels in the lower part of the UEVF (180 metres to 250 metres below the surface) have recovered as expected.
- Graph 2 shows that groundwater levels in the upper part of the UEVF aquifer, located at depths varying between 40 metres and 140 metres below the surface, show no impact of pumping test and continue to gradually increase in pressure.
- Graph 3 importantly shows the shallowest aquifers, Demons Bluff Formation (DBF) and Perched Water Table (PWT), located 5 metres to 50 metres below the surface and closest to the Anglesea River system, are responding only to natural climate variations and have shown no impact as a result of the pumping test.

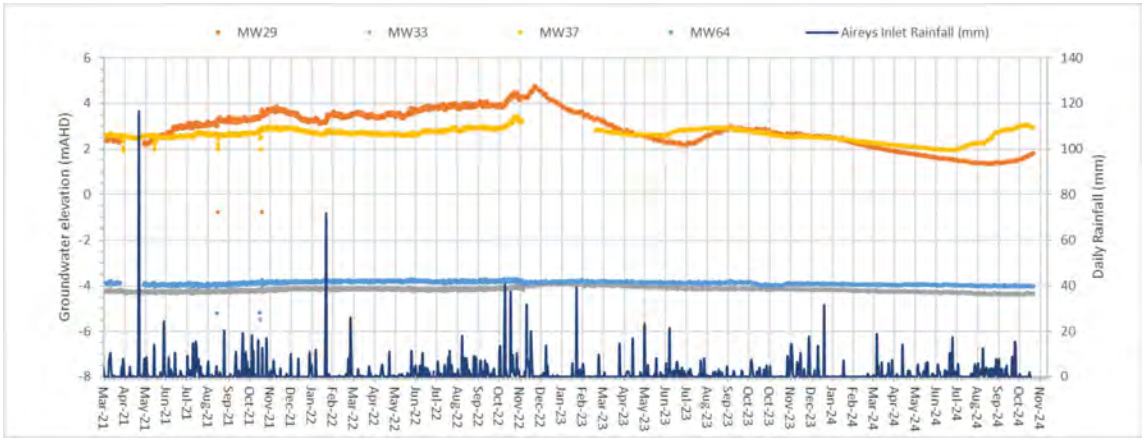


Graph 1: Groundwater level (pressure) trends for the lower part of the UEVF aquifer (approximately 200m depth) show declines as modelled. Note: Datalogger re-deployed in WB04 on 20 February 2023. No data between November 2022 and February 2023. The datalogger in WB12 and WB14 could not be downloaded on the 13 August 2024. Datalogger data is not available for the period 8 May 2024 to 14 November 2024.



Graph 2: Groundwater level (pressure) trends for the upper part of the UEVF aquifer (approximately 40m to 140m depth) show no impact of pumping.

Data logger failed in UEVF MB2 and data could not be retrieved from August to November 2023.



Graph 3: Groundwater level trends in the DBG / PWT aquifer (approximately 5m to 50m depth) shows no response to the pumping test. Datalogger re-deployed in MW37 on 20 February. No data between November 2022 and February 2023.

Barwon Water Anglesea borefield monitoring data

For more information on the Anglesea borefield and the monthly updates please see the Barwon Water website.

Appendices

The data in this monthly report includes all data up to the most recent groundwater data collection, on 14 November 2024.

Note: Bores DBG MB01, DBG MB02, DBG MB03, DBG MB05, DBG MB07 and DBG MB08 are not shown on the graphs in the section below as these bores are currently dry and have no historical water level.

Bores DBG MB04 and DBG MB06 are saturated.

Key Considerations

In addition to the trigger level assessment, **Table 1** provides general comments, where appropriate, based on review of the water level and water quality results to date for the following Figures and Tables where appropriate.

Any new recommendations for TWG consideration are underlined within the table; there are no new recommendations.

Table 1: General comments based on a review of the water level and quality data to date.

Figure / Table Reference	Bore ID	Comment	Action / Investigation Findings
Figure 4	WB4	The drawdown is as expected however as reported in previous reports the nature of the drawdown response continues to appear "dampened" when compared to others. This could be as a result of several hypothesis listed in previous months. As part of the Bore Assessment Program (BAP), the datalogger was removed on June 20 to allow wireline (geophysical) logging and downhole camera inspection. The re-sleaved WB4 will form part of the monitoring program moving forward with the datalogger re-deployed on November 5.	In 1977, this well was repaired by re-sleaving with an 8-inch casing. As part of the BAP, the drilling contractor advanced down through the bore annulus to 195m. A geophysics survey was completed and the screened intervals were confirmed at 117-120 m, 161-164m, 176-182m. It is likely that other screened intervals were installed but these could not be confirmed by the geophysics survey. The re-drilling of the bore as part of the BAP was successful. A decision was made to re-sleave WB4. Lithological information and geophysical logs were reviewed to enable a suitable design. The following bore design summary is provided: • 50mm diameter screen and casing • Screen intervals at 117-120m, 161-164m, 176-182m, 191-194m. The casing was perforated at 192.5m • Fibre-glass casing was used from 0-117m • Stainless steel screens and blank casing were used from 117-195m • A sump was installed from 194-195m. The groundwater response observed since this bore was repaired now exhibits behaviour expected of this bore.
Figure 4	WB12	As reported previously, the drawdown is smaller than expected. WB12 is the closest bore to the pumping bore	As part of the BAP, the drilling contractor has identified a number of integrity issues with this bore: • Collapsed casing at 90m;

Figure / Table Reference	Bore ID	Comment	Action / Investigation Findings
		(WB16; 28m away) and does not show the greatest drawdown. This is observed at WB14 which is 288m from WB16. This could be as a result of several hypothesis listed in previous months.	• Damage to the casing (large holes) between 107m and 117m. • Significant debris throughout with a large obstruction at 193m. • Screens blocked by silt / sediment and likely iron bacteria. At this stage WB12 forms part of the monitoring network. Following pump shut down and the collection of recovery data, further analysis will be undertaken to assess the response in WB12. Depending on the outcomes of the data analysis, WB12 may be: • Rectified by re-sleaving the casing issues, removing the obstruction at depth and cleaning the screened intervals; or • Decommissioned. Note any decommissioning will not be undertaken whilst the pump test is active.
Figure 4 **Figure 5**	WB16	The extraction pump within WB16 has recorded a number trips resulting in a number of restarts. The ongoing intermittent fault continues to be investigated and appears to be related to the diesel generator providing power to the pump. This is not expected to impact the overall objective of the pumping test.	All equipment items have been recently serviced and inspected by the original equipment manufacturers. A number of generator components have been changed out or modified. Investigations continue through Sept and Oct and the intermittent issue was rectified, allowing for uninterrupted (other than refuelling) operation through November to the end of Stage 1 on December 8.
Figure 7	UEVF MB8	As reported previously UEVF MB8 exhibits a pressure ~20m higher than UEVF bores MB1 to MB7. The upper sands seen within UEVF MB1 to MB7 are not present at UEVF MB8. In addition, the water chemistry of this bore is considerably different to the other near mine water body bores. For background, this bore was developed at <1L/sec for ~48 hours (air lift). Water quality stabilised after 3.5 hours with stabilised water quality reported as pH 9.59 and EC 1373 µS/cm which is typical of water within coal formations. However, the pH and TDS from the May and June sampling was considerably higher than during bore development.	The higher groundwater levels seen in this bore are likely representative of the confining coal and clay which the bore is screened. These levels are also similar to the pressures seen in the decommissioned piezometers historically installed along the south wall (refer Figure 4-5 of the Monitoring Plan). This bore is no longer used to report for groundwater quality.
Figure 12	SOB 116459	Trigger level 3 was briefly reached once for a total of 2 days	Notwithstanding that Alcoa Stage one pumping ceased on 8 December 2021, an investigation trigger was reached

Figure / Table Reference	Bore ID	Comment	Action / Investigation Findings
		in the month before recovering above the level.	for one of the 12 nominated trigger bores with SOB 116459 trigger briefly exceeded during the period. Prior to stage two commencing, this trigger level will be reviewed with the TWG. A review of previous trigger rule 3 exceedances was included in the December TWG report, including that the trigger being reached is believed to be as a result of multiple factors including climate, bore condition and also potentially the pumping test. Recovery data will continue to be monitored.
Figure 13	UEVF MB3	UEVF MB03 is the deepest bore in the UEVF series. UEVF MB03 is the closest bore to the mine sump. As the mine pit water body fills, the delayed water level response observed is likely due to the compressibility of the aquifer. The other UEVF bores are located at a distance from the mine sump where the delayed response is not observed.	Continue to monitor quarterly.
Figure 18 and Figure 27	DBG MB6	The pH at DBG MB6 ranged between 4.28 and 7 from February 2021 to November 2024. Over the last 12 months, pH has declined from 6.02 to 4.28. The TDS has remained constant at around 2,500 mg/L since monitoring commenced in April 2021. The pH change may be associated with mineral dissolution in the backfilled overburden, however the change is unknown at this stage. The mine pit water level is currently below the water level in the backfilled overburden. The groundwater flow direction is still towards the mine pit.	Continue to monitor quarterly.
Figure 18	Mine Water Body	The pH in the Mine Water Body ranged between 3.4 to 4.2 from February 2023 to November 2024. The pH recorded in November 2024 was 3.44 which is consistent with past observations. The TDS has remained constant at around 1,600 mg/L since monitoring commenced in April 2021.	Continue to monitor quarterly.
Figure 18 and Figure 28	DBG MB04	Since February 2023, TDS has increased from 2,140 to 4,000 mg/L. Figure 28 suggests this increase is driven by an increase in chloride.	Continue to monitor quarterly.

Figure / Table Reference	Bore ID	Comment	Action / Investigation Findings
Figure 8, 16 and 17	MW29, MW33, MW37 and MW64	Continual falling groundwater levels are observed in these shallow screened well as a result of lower than average rainfall. This supports our conceptual understanding of water level behaviour in this area which is strongly related to rainfall and evapotranspiration.	Continue to monitor quarterly.

Table Notes: **m** = metres **L** = Litre **cm** = centimetres **µS/cm** = microsiemen per centimetre

Monitoring bore hydrographs (entire network)

Water Quality Results

Table 2 presents the TDS and pH results from sampling undertaken on 14 November 2024 for each bore where water was above the well screen and where it was a part of the GME. **Figure 18** presents the TDS and pH plots for monthly GMEs.

Figures 19 – 26 present piper plots for the monthly GMEs (April 2021 to November 2024). The results indicate groundwater, and mine water are similar by water type and mostly dominated by calcium sulfate and sodium chloride. Groundwater from DBG MB4 and DBG MB6 is sodium chloride dominant. **Figure 29** presents trend of TDS and chloride/bromide ratios. The results indicate there is no evidence of groundwater mixing.

Table 2 Water quality data from sampling undertaken in November 2024.

Sample Location	TDS (mg/L)	pH

Alcoa

Alcoa Anglesea

Community Engagement Report

A summary of the feedback Alcoa received from open house sessions related to a potential mine water filling strategy

Published July 2024

Alcoa acknowledges Wadawurrung People as the Traditional Owners of the land where we operate and we pay our respects to their Elders past, present and emerging.

Kuarka Dorla Dja, (Anglesea) is a place where Wadawurrung ancestors came to fish for mullet.

Bounded by intricate waterways flowing out to the Warri (salt water), sand dunes steeped in heritage, and the high point of country the Anglesea Heathlands, where the Mirri (sun) rises on the Warri (salt water) and sets across the heath.

We acknowledge Bunjil as the Creator Spirit, who continues to watch over the land and guide us all on our journey and responsibility to heal country.

Executive summary

Between 23 and 25 May 2024, Alcoa hosted three open house sessions in Anglesea, providing opportunity for local community members to learn about the company's potential plans to fill its mine pit with groundwater, and hear the latest on rehabilitation of the former mine and power station sites.

The sessions were part of a comprehensive community engagement initiative, which leveraged a number of communication channels to generate community awareness and attendance. In total, 102 members of the local community dropped in to the sessions, seizing the opportunity to discuss the technical findings with Alcoa representatives and their technical experts, demonstrating strong community interest.

The feedback collected was mostly positive in nature, with 88 per cent of attendees feeling more informed about the Anglesea Mine Rehabilitation and Closure Plan and 86 per cent feeling better informed about the viable options for filling the mine pit.

Sentiment analysis of the feedback collected revealed approximately 14 per cent of responses were negative, with the majority neutral (54 per cent) or positive (32 per cent).

While some attendees provided feedback about the technical nature of the information presented, the majority of attendees reported that they appreciated the detailed technical information and valued the opportunity to engage directly with Alcoa's team.

Positive comments highlighted the sessions' informative nature, the professionalism of the presentation, and the accessibility of the representatives.

Many attendees expressed support for Alcoa's efforts and a desire to stay informed about the next steps, and also expressed an interest in site tours.

Introduction

After 46 years of operation, Alcoa's Anglesea Power Station and Coal Mine was permanently closed in August, 2015.

Following extensive consultation with the community, Alcoa published the draft Anglesea Mine Rehabilitation and Closure Plan in 2017, underpinned by key geotechnical, hydrological and vegetation technical studies undertaken by experienced consultants.

Since then, major earthworks and revegetation activities completed in 2020 have delivered a safe, stable and sustainable landform, which will require ongoing monitoring and maintenance over the next decade.

Alcoa have a regulatory obligation to deliver the final Anglesea Mine Rehabilitation and Closure Plan, and in order to achieve this an approved strategy to fill and maintain the mine pit with water is required.

A range of potential options to support filling the mine pit in a timely manner have been investigated and of these, the only two currently feasible options are the use of groundwater from the Upper Eastern View Formation (UEVF) which would see the mine pit filled in seven to 10 years, or natural fill which is estimated to take approximately 50 years.

Mine water filling strategy

Approximately 18 gigalitres of water is needed to fill the mine pit. As at April 2024, there is approximately three gigalitres of water present.

Alcoa's preferred option is to fill the mine pit over seven to 10 years, achieved through supplementing natural filling of the mine with a combination of UEVF groundwater and potential peak flows from Salt Creek. Note: the current focus is the potential use of UEVF groundwater, with potential peak flows from Salt Creek not currently being explored.

Extensive technical work undertaken over more than three years has not identified any adverse impact on groundwater dependent ecosystems, including the Anglesea River.

Alcoa understands the community's interest in the Alcoa site, and has continued to actively engage with the Anglesea community and key stakeholders.

This report outlines the feedback Alcoa received during the open house sessions related the potential use of UEVF groundwater to support the mine water filling strategy.

A copy of the information boards displayed at the open house sessions are provided within Appendix 1.

The journey to now

2016 | Shared vision

Community engagement undertaken to capture the community's views and aspirations for future land uses.

Considerate of the feedback, the shared vision including five guiding principles were developed to inform development of the draft Anglesea Mine Rehabilitation and Closure Plan.

2017 | Draft Mine Rehabilitation and Closure Plan

The shared vision was incorporated into the draft Anglesea Mine Rehabilitation and Closure Plan, which was then presented to the community.

The feedback revealed high levels of support for the plan, including for the re-profiling of slopes, re-vegetation with native species, and the creation of a large water body.

Considerate of the feedback, the draft Anglesea Mine Rehabilitation and Closure Plan was submitted to the Victorian Government in September 2017.

2018 - 2020

Major earthworks program and vegetation strategy deliverables of the draft Anglesea Mine Rehabilitation and Closure Plan were implemented and delivered a safe, stable and sustainable landform.

A number of potential mine water filling options were explored during this period including recycled water, seawater, and the use of the deeper LEVF aquifer – each ultimately determined to be unfeasible for a variety of reasons.

2021 - 2024

Extensive technical work undertaken to explore the possibility of using UEVF groundwater to fill the mine pit as part of the mine water filling strategy.

This included analysing historical groundwater behaviour, review of independent historical studies, comprehensive geological studies, a 2021 groundwater pumping test with active regulatory oversight, and development of the Anglesea regional groundwater model in collaboration with Barwon Water.

May 2024

With the technical work nearing completion, the local community were invited to discuss the resultant findings and share their feedback on the potential strategy to fill the mine pit.

Community engagement snapshot

A total of 102 community members dropped in to one of three, two-hour sessions hosted at the Anglesea Bowling Club, with many spending a significant period of time reading the information boards displayed around the room and conversing with Alcoa representatives and their technical experts.

Session dates, times and attendee breakdown:

Thursday 23 May
4:00pm to 6:00pm

24

Friday 24 May
10:00am to 12:00pm

16

Saturday 25 May
10:00am to 12:00pm

62

How the sessions were advertised

A multi-channel approach was adopted to inform the community and stakeholders about the open house sessions. Copies of the advertising collateral are provided within Appendix 2.

979

email invitations to individual Alcoa database subscribers.

507

visits to a dedicated web page advertising open house sessions and featuring FAQs.

Three

event listings on the Surf Coast Shire's website event calendar.

One

advertorial in the Surf Coast Times.

One

editorial in the Armstrong Creek Times, resulting from an Alcoa issued media release.

Multiple direct outreaches

to local community and interest groups, resulting in numerous Facebook posts and a dedicated Anglesea Community Network newsflash (e-newsletter).

Multiple direct outreaches

to key stakeholders including local and state government representatives, authorities, and regulators and ongoing engagement with the Wadawurrung Traditional Owners group.

One

off-page Facebook and Instagram campaign - high level results displayed to the right.

A full breakdown of the campaign content and results is provided within Appendix 3.

Metric	Results
Reach *Number of accounts/users who saw content at least once*	3,819
Frequency *The average number of times each account saw the ads*	2.8
Impressions *Number of times the ads were on screen*	13,945
All Clicks *The number of clicks, taps or swipes on the ads*	103
Link Clicks *The number of clicks, taps or swipes within the ad that led to the dedicated website*	32
Engagements *Number of actions people took involving the ad.*	732

Feedback summary

Alcoa engaged independent communications agency, Keep Left, to capture community feedback throughout the sessions via a simple questionnaire - comprising three questions.

Prior to leaving the sessions, community members were invited to provide feedback, by completing the questionnaire themselves, or verbally while one of the two Keep Left representatives recorded the response.

Of the 102 attendees, more than half (65) chose to provide feedback.

The following data analysis aims to summarise the feedback provided, including categorisation of common themes and sentiment.

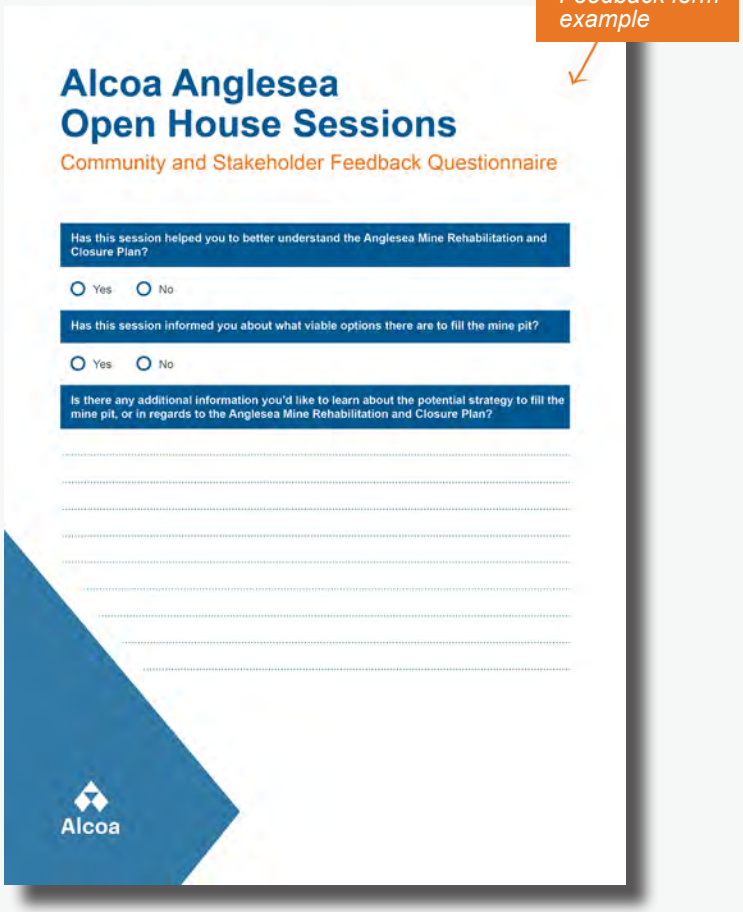
A copy of the completed feedback forms are provided within Appendix 4.

Considerations when reading this report

Several factors influenced the gathering and analysis of the quantitative data and qualitative feedback and should be considered before reading. These include:

- The information presented in this report was collected from voluntary feedback and therefore the sample is not necessarily statistically representative of Anglesea population.
- The collation and analysis of data has been undertaken by Keep Left.
- The comments referenced within this report are often a direct quotation of feedback provided by respondents within their feedback. The accuracy of content provided within this feedback has not been assessed, and therefore should not necessarily be viewed as a statement of fact, but rather a representation of the opinions and perceptions of respondents.
- Feedback quoted in this report may have been edited to correct spelling and grammar to aid readability. Care has been taken not to change the sentiment, tone or context.

Feedback form example



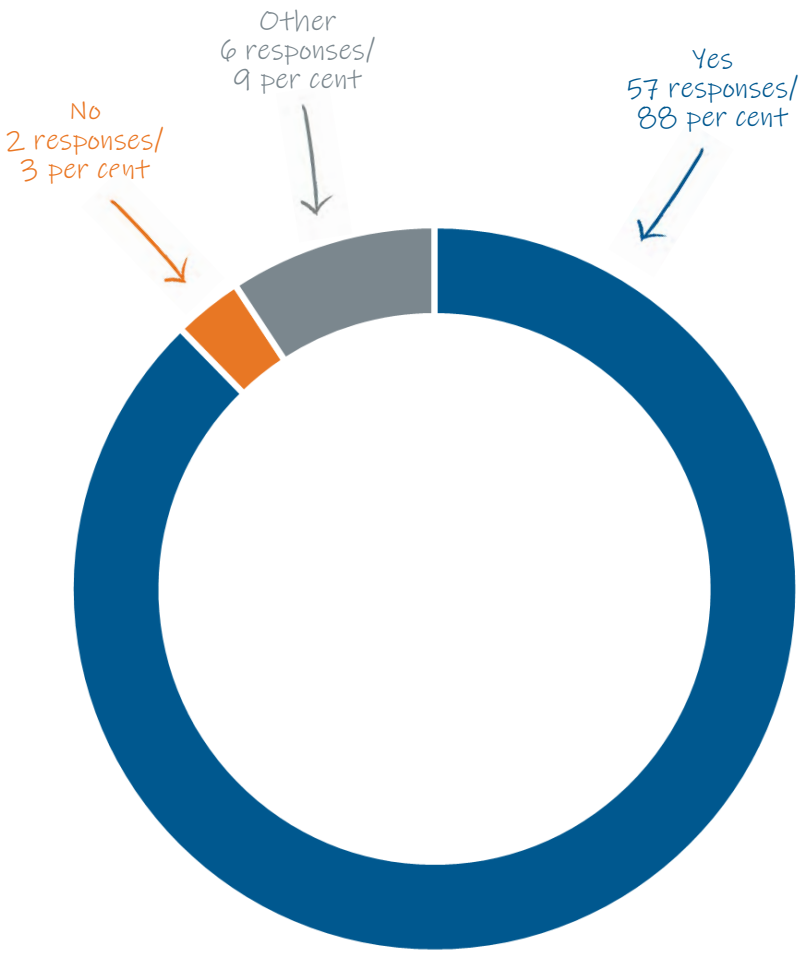
Question one

Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

○ Yes ○ No

Insights

- The vast majority (88 per cent) of attendees responded ***yes***
- Some respondents (9 per cent) didn't provide a clear response or made an alternative option, such as ***maybe*** - for the purpose of this analysis, these have been categorised as ***other***
- Only two attendees (3 per cent) responded ***no***



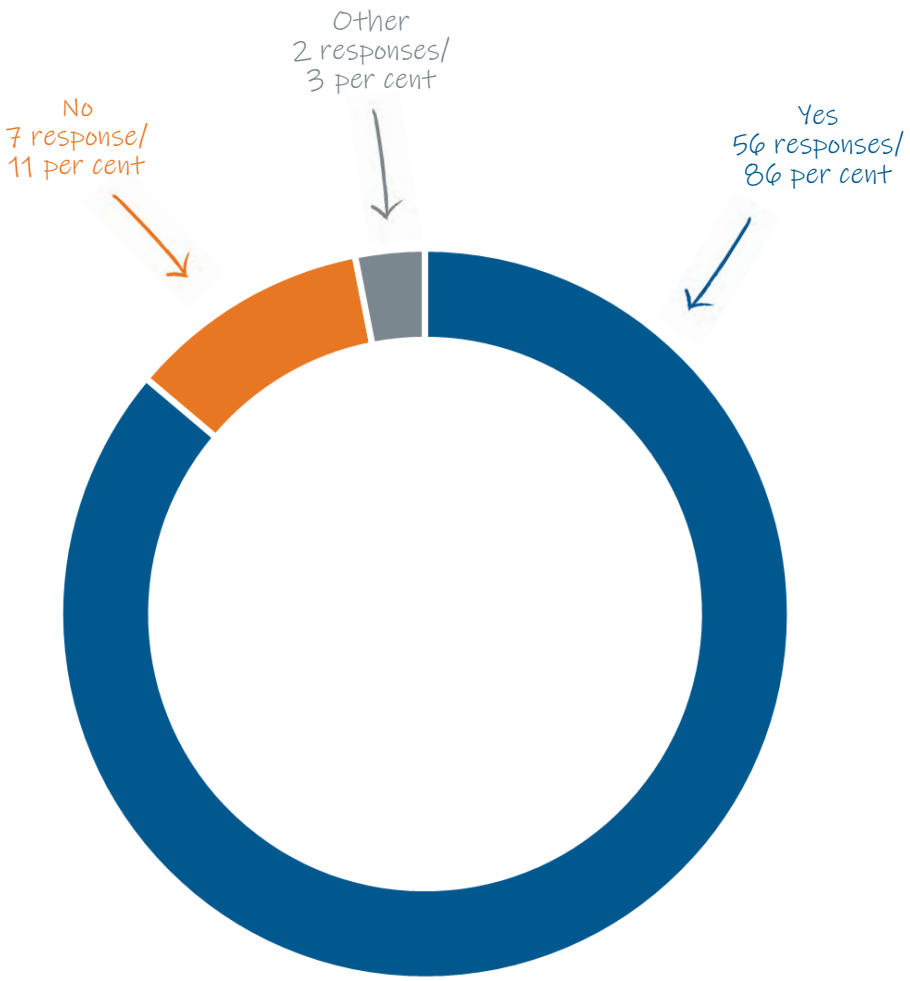
Question two

Has this session informed you about what viable options there are to fill the mine pit?

○ Yes ○ No

Insights

- The vast majority (86 per cent) of attendees responded ***yes***
- Seven respondents (11 per cent) responded ***no***
- While two were categorised as ***other***



Question three

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

Insights

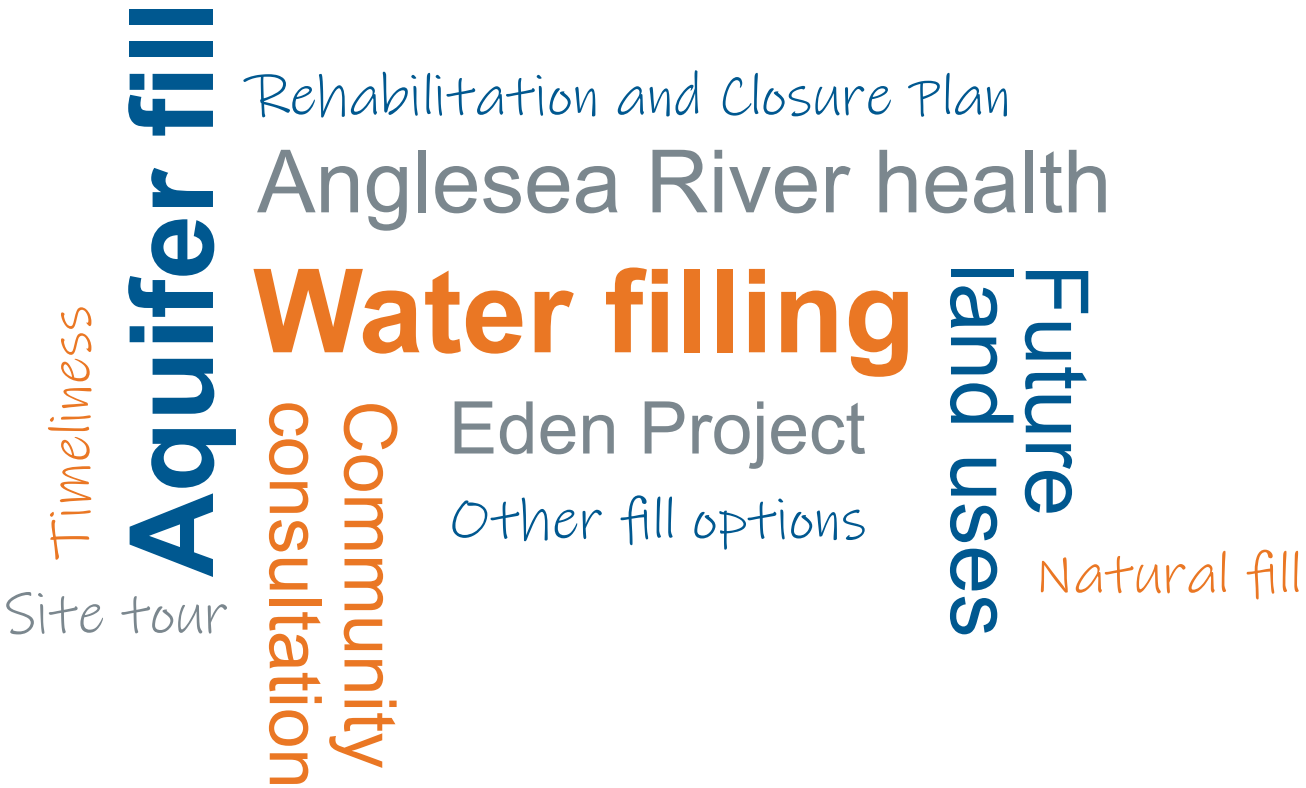
The nature of this question prompted respondents to say what ***additional*** information they would like regarding the mine water filling strategy and broader Anglesea Mine Rehabilitation and Closure Plan, whilst also providing opportunity for general comments or feedback.

While some respondents directly answered this question by specifying the exact information that they would like, many others used the free text field as an opportunity to provide their views and opinions about the project.

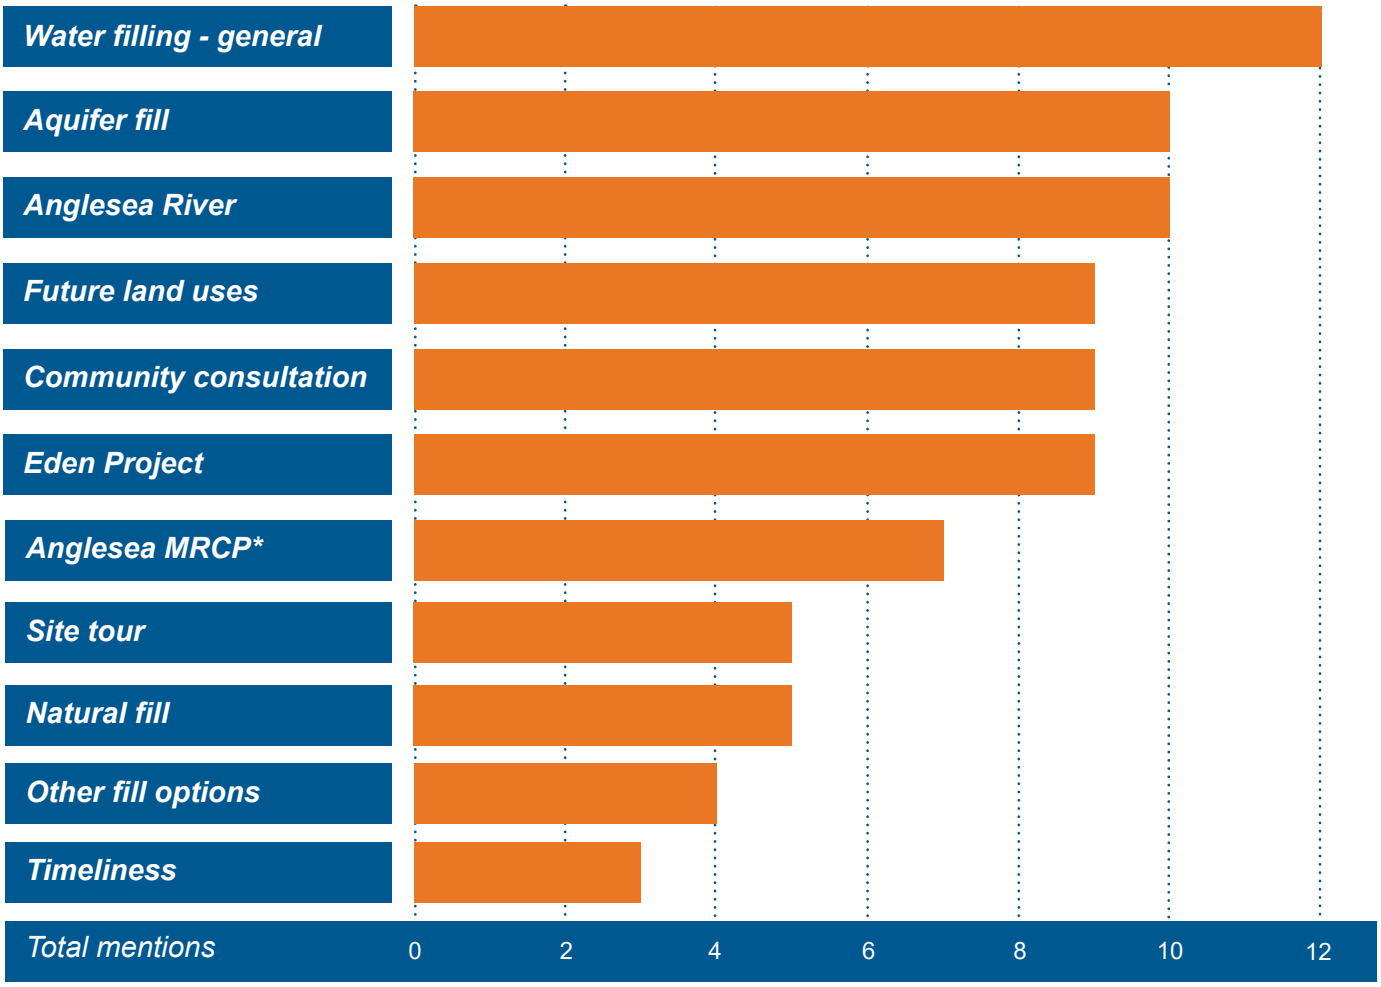
Given the level of detail provided by respondents to this question, Keep Left has undertaken some additional analysis to assess sentiment and categorise the most common themes.

Most responses to the question referenced multiple topics or themes. As a result, most individual feedback forms were tagged as addressing multiple categories.

Only two respondents chose not to respond to this question at all.



Feedback themes



*Mine Rehabilitation and Closure Plan

Water filling

The mine water filling strategy was the most common theme of feedback for question three, which is unsurprising given the topic was the focus of information provided at the open house sessions, and the subject of most discussions. Comments collected were categorised as being either general in nature (***Water filling - general***), or as indicating a preference for an ***aquifer fill*** or ***natural fill***. Comments about water filling were often connected to commentary around local waterways, which were categorised as ***Anglesea River***.

Examples of water related feedback include:

> *"How can we fill it quicker. Found it fascinating how much water there it under there. If people understand how much water there is underground it will help them understand."*
>
> *"Recycled water and sewerage. What is the quality of the water from the Anglesea sewerage plant, couldn't that be used?"*
>
> *"There is a lot to digest, lots of good information. Not convinced about aquifer but appreciate being able to talk about option, with teams."*
>
> *"Happy with the info about the river history."*
>
> *"For someone who doesn't understand water it was well presented with helpful people around."*

Information detail and complexity

A high-level of detailed information was provided about pumping tests, groundwater, aquifers, hydrology and geology at the sessions. This was supported by explanations from Alcoa representatives and their technical experts.

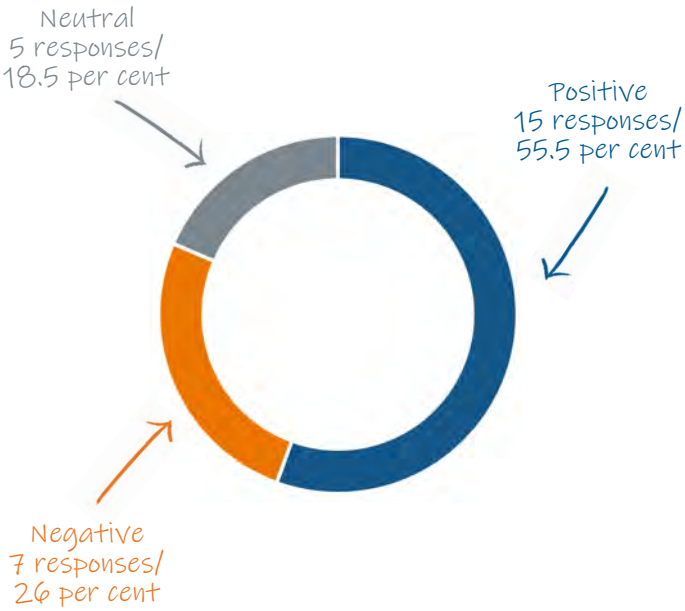
Many respondents expressed appreciation about the level of detail provided, which was reflective in many attendees spending a considerable amount of time digesting the information and chatting with representatives.

There were also a number of comments from attendees expressing a feeling that there was too much information provided and that it was too technical in nature, despite Alcoa's attempt to explain what by its very nature, is a complex and technical project.

Given many respondents had feedback about the level of detailed information provided, this was assessed as a sub-category.

Examples of the differing opinions regarding information complexity include:

> *"Graphs were too technical, graphs need to be better explained, also labelled…would like to see more progression and plans moving forward."*
>
> *"Well presented - for someone that doesn't understand water it was well presented and helpful people around."*



Given the majority of feedback regarding information complexity was categorised as either positive or neutral, it is reasonable to assess that Alcoa did a good job of presenting the community with a significant amount of information, in a way that enabled attendees to be able to make their own assessments.

Presenting all of the research data, while also seeking to educate attendees about this complex project is a challenge, and it's reasonable to err on the side of providing more information, than to not present all of the detail and facts.

Future land uses

Respondents seeking more information about future land uses, including the Eden Project for Anglesea concept and broader Anglesea Mine Rehabilitation and Closure Plan (MRCP), were the next most common feedback themes.

Examples of future land use related feedback include:

> *"Interested in Eden Project or if there are viable alternatives. Also interested in what progress to make sure water is provided and has the right impact. Also, why do you want water, not soil?"*
>
> *"Not at this stage. Will there be a block of land for housing? Interested in Eden Project."*
>
> *"Displays really good - balance of technical and well explained. Good doing three sessions to inform community."*
>
> *"I'd like to get an update on Eden Project and in regard to the filling."*
>
> *"Good overall - would like more info on Eden Project update."*

Other

Other feedback included requests to participate in tours of the former mine site, to see the rehabilitation activities first hand, or were more general about the overall consultation process.

Examples include:

> *"I would love to participate in a site tour."*
>
> *"Looking forward to a tour of the area."*
>
> *"Where is Torquay's storm water going to go? Would be good to do tours & have a better understanding and information Get the kids involved a teach them about the aquifer."*
>
> *'Thinks session is good - important to engage the community. Fantastic to have the team that actually work on the project here - especially Chris for technical details. Wants to do a tour overall supportive."*

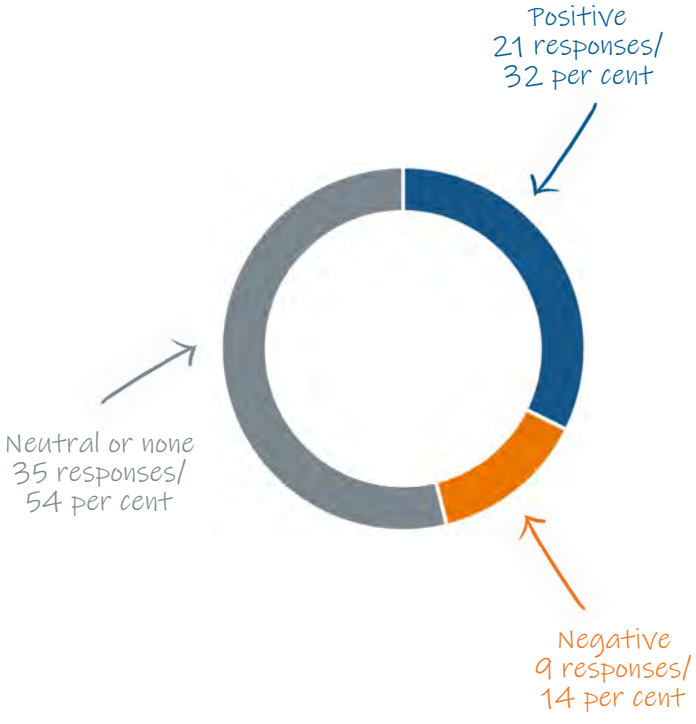
Sentiment analysis

In terms of sentiment, the majority of feedback (56 per cent) was assessed as being either neutral in tone, or that no sentiment could be gleaned from the respondent.

Many of these were responding to the question as it was intended, simply providing areas where more feedback would be appreciated.

Examples of neutral feedback include:

> *"I'm already informed as a member of the River Advisory Council and Angair, but it's an opportunity to see all the detail as I attend a lot of community information sessions."*
>
> *"Much more technical than I thought it would be. I would like to see more of a timeline and progression too."*
>
> *"I feel like you guys know more about this than I do and I'm a local. I'm just interested to see what's happening."*



Just under a third (32 per cent) of respondent feedback was assessed as being positive in nature.

Examples of positive feedback include:

> *"As Mr. Nike says, "Just do it"."*
>
> *"Opportunities galore. Well-presented and supported."*
>
> *"People seem very knowledgeable."*
>
> *"Over the years since the mid-1960s I have supported everything Alcoa has done for the town. From employment of locals to support of almost all locals around town clubs and organisations in the form of donations. Their commitment to rehabilitation of the mine site to demolition of power station and the ongoing attention to water mine filling, reshaping the mine and monitoring the nature drainage has been commendable."*

Feedback from nine respondents (14 per cent) was assessed as being negative in nature.

Examples of negative feedback include:

> *"Doesn't understand why Alcoa wants to 'fill so quickly'. Don't like Eden Project, doesn't want it to be turned into hotels and conference centres. No benefits for Anglesea Community."*
>
> *"The information provided was relatively complex and would require further examination to fully understand Alcoa Arguments. Too much information - too little time. I am most concerned that Alcoa is suggesting that climate change is a major driver of reduced flows and acidity in the Anglesea River without considering the impact of the mine void (and cone of depression on the river."*

Post-it board

Attendees were invited to provide additional feedback on post-it notes to be placed on a board for others to see.

Only a few attendees chose to provide feedback on the board. However, Keep Left took a selection of quotes provided in early feedback forms to write up on the board to encourage more respondents.

General observations

While not captured in the feedback collected, a number of general and positive observations were noted during conversations Alcoa representatives and technical experts had with attendees.

These observations touched on topics such as Coalmine Road access, freehold land, affordable housing options and the suitability of the Anglesea Sewage Treatment Plant for filling the mine pit.

Digitised version of the feedback board

Conclusion

Thanks is extended to all of the community members who took the time to drop in to a session and hear firsthand how the technical work is informing Alcoa.

Throughout the sessions, Alcoa representatives and technical experts engaged in numerous constructive conversations with individuals who showed genuine interest in the work being undertaken.

Many were equally as appreciative of the opportunity to be informed, with positive comments highlighting the sessions' informative nature, the professionalism of the presentation, and the accessibility of the representatives.

This notion also aligns with the majority sentiment gleaned from the feedback forms and from the data analysed.

A summary of all the feedback collected during the open house sessions is detailed below:

- 88 per cent of feedback received indicated that attendees felt they better understood the draft Anglesea Mine Rehabilitation and Closure Plan
- 86 per cent of the feedback received indicated that attendees felt informed about what viable options there are to fill the mine pit
- The majority of feedback (56 per cent) was assessed as being either neutral in tone, or that no sentiment could be gleaned from the respondent, while 32 per cent was positive and 14 per cent negative
- Community members remain interested in a variety of other aspects related to the future of the site

Appendix 1 | Information boards

Welcome

Alcoa acknowledges Wadawurrung People as the Traditional Owners of the land where we operate and we pay our respects to their Elders past, present and emerging.

Kuarka Dorla Dja, (Anglesea) is a place where Wadawurrung ancestors came to fish for mullet.

Bounded by intricate waterways flowing out to the Warri (salt water), sand dunes steeped in heritage, and the high point of country the Anglesea Heathlands, where the Mirri (sun) rises on the Warri (salt water) and sets across the heath.

We acknowledge Bunjil as the Creator Spirit, who continues to watch over the land and guide us all on our journey and responsibility to heal country.

Alcoa

Mine Rehabilitation and Closure Plan

Delivering a space for community

Alcoa have a regulatory obligation to deliver the final Anglesea Mine Rehabilitation and Closure Plan.

Major earthworks and revegetation activities completed in 2020, have delivered a safe, stable and sustainable landform, which will require ongoing monitoring and maintenance over the next decade.

The key remaining aspect of the Plan is an approved strategy to fill and maintain the mine pit with water.

A range of potential options to support filling the mine pit in a timely manner have been investigated and of these, the only two currently feasible options are the use of groundwater from the Upper Eastern View Formation (UEVF) which would see the mine pit filled in seven to 10 years, or natural fill.

Options considered

- UEVF groundwater - Alcoa licence
  LEVF groundwater - Barwon Water licence
- Recycled water - Breamlea treatment plant
- Natural fill - estimated to take approximately 50 years
- Seawater and/or desalination
- Salt Creek restoration

Post completion of earthworks and revegetation 2022

Mine Water Filling Strategy

Approximately **18 gigalitres** of water is needed to fill the mine pit. As at April 2024, there is approximately **three gigalitres** of water present.

Alcoa's preferred option is to fill the mine pit over seven to 10 years, achieved through supplementing natural filling of the mine with a combination of UEVF groundwater and potential peak flows from Salt Creek. Extensive technical work undertaken over more than three years has not identified any adverse impact on groundwater dependent ecosystems, including the Anglesea River.

Why water?

Creating a water body supports:

- Benefits to the environment, the regional economy and the community from the future land use of the rehabilitated landscape
- A critical fire break to minimise fire risk to the Anglesea township
- Geotechnical stability through the weight of water at the base of the mine

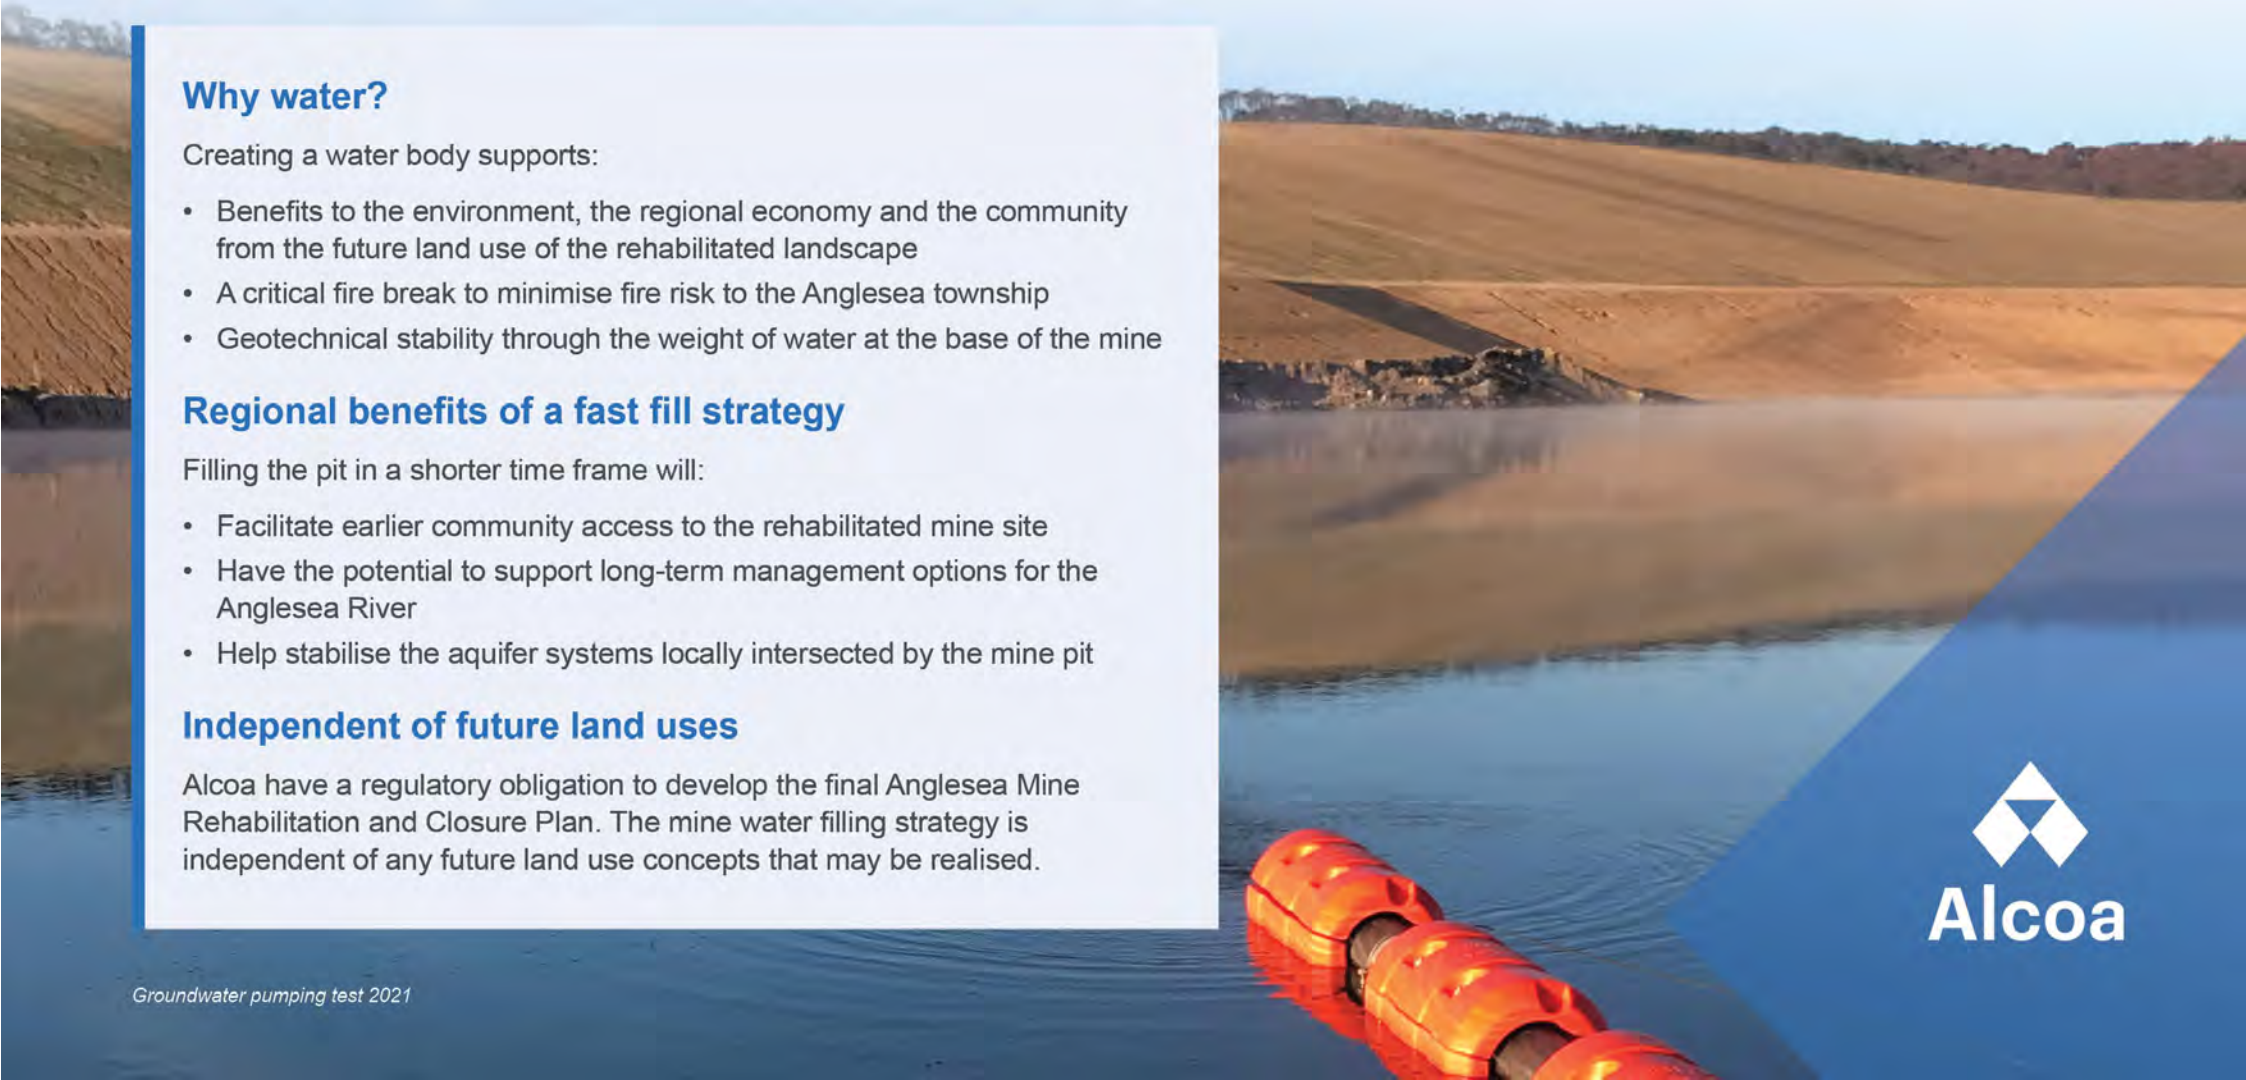
Regional benefits of a fast fill strategy

Filling the pit in a shorter time frame will:

- Facilitate earlier community access to the rehabilitated mine site
- Have the potential to support long-term management options for the Anglesea River
- Help stabilise the aquifer systems locally intersected by the mine pit

Independent of future land uses

Alcoa have a regulatory obligation to develop the final Anglesea Mine Rehabilitation and Closure Plan. The mine water filling strategy is independent of any future land use concepts that may be realised.



Groundwater pumping test 2021

Alcoa

What's below the surface?

Understanding the hydrogeology

Different layers of geology impact the interaction between groundwater and surface water.

The Upper Eastern View Formation (UEVF) hosts multiple sub-aquifers, located either in the upper section (upper sands) or lower sections (lower sands).

Separating the upper and lower sub-aquifers are multiple low permeability layers of coals and sandy clays.

The permeabilities of these layers are typically equivalent to EPA specified landfill liner requirements.

Water pressure is higher in the saturated low permeability layers of coals and clays compared to the upper and lower sands – which indicates a degree of disconnectivity.

Clay also lines the base of the creek systems, inhibiting surface and groundwater interaction.

Exploring historical groundwater behaviour

What story does history tell?

Groundwater pressures in the lower sands of the UEVF have ranged between -90 to 0 mAHD. Since the 1990s when shallow aquifer monitoring began, this lower aquifer depressurisation has not impacted the shallow aquifers' water table, indicating the 'cone of depression' is confined to the pumped aquifer.

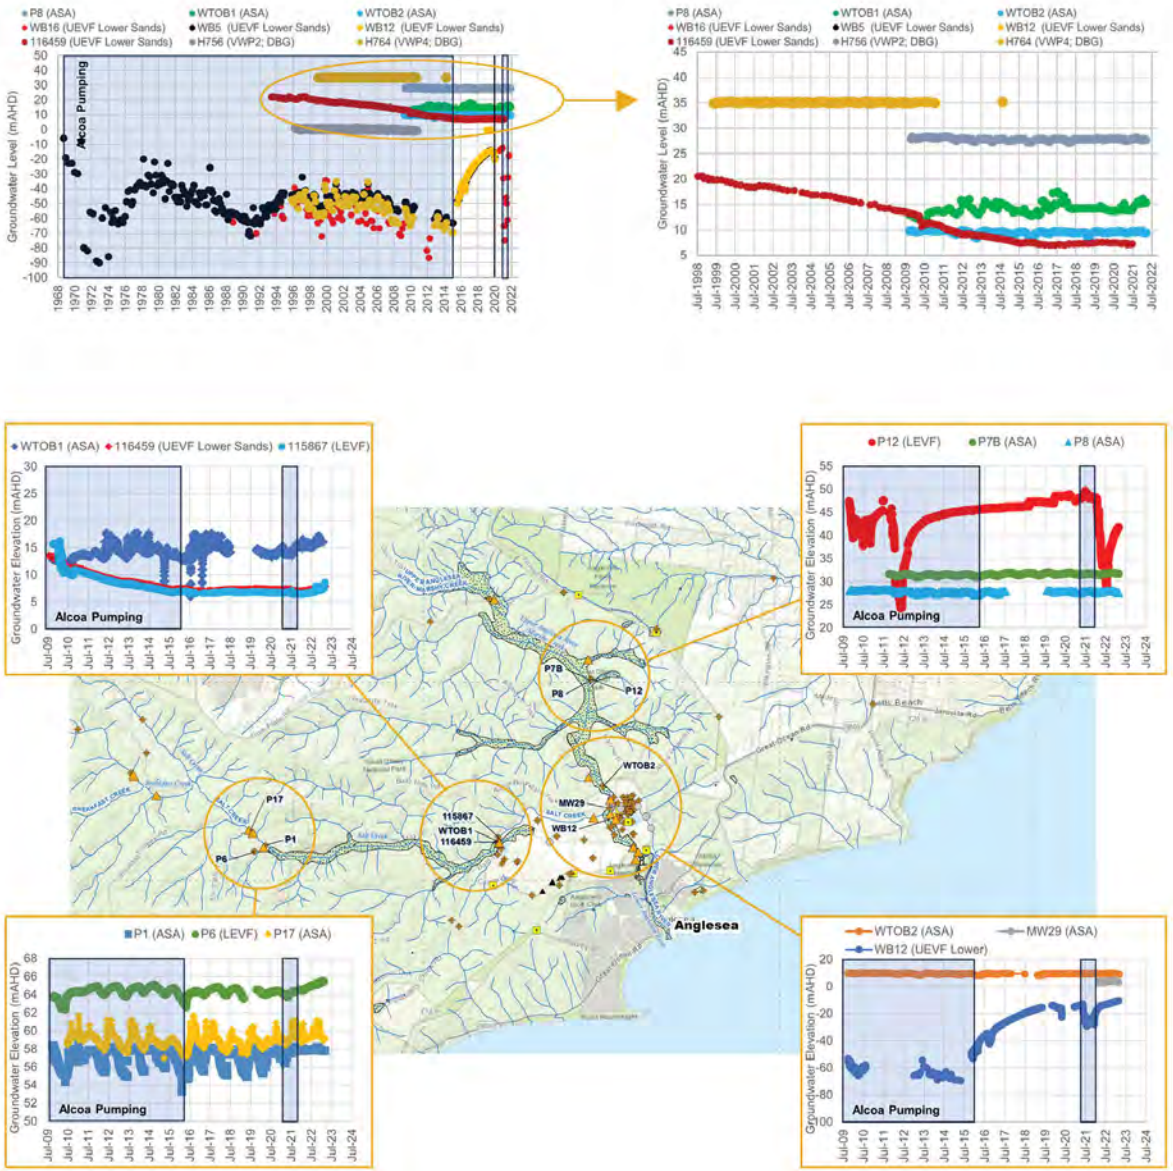
Groundwater levels in the alluvial swamp aquifer (ASA) respond closely to seasonal rainfall - declining when the proceeding months are low in rainfall and/or evapotranspiration is high.

Groundwater trends in the ASA behaves similarly regardless if the UEVF potentiometric surface or 'cone of depression' is higher or lower than the water table in the ASA.

For example:

P8 (screened in the ASA with potential gaining conditions) experiences similar behaviors as WTOB2 (screened in the ASA with potential losing conditions).

This indicates that at these locations, the base of the ASA is relatively impermeable with the clay layer retarding vertical water movement. Rather climatic conditions such as rainfall and evapotranspiration control water level behaviour and consequently, timing of surface water flow.



Groundwater pumping test

In 2021 Alcoa undertook a groundwater pumping test on the UEVF aquifer to help determine if UEVF groundwater could be used to fill the mine pit.

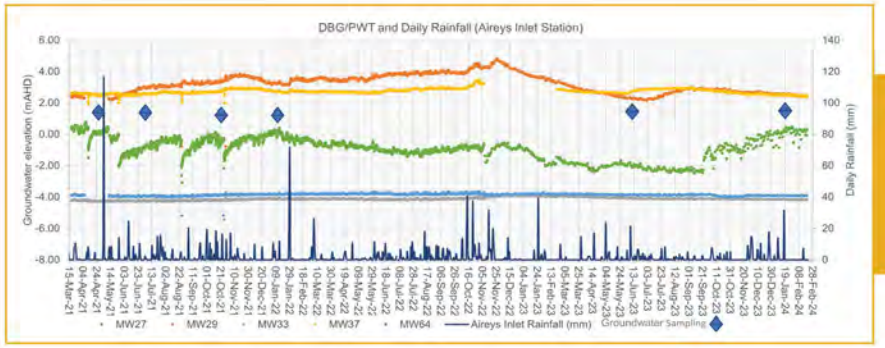
The test was undertaken by expert hydrogeologists between May and December 2021, with oversight by a Victorian government co-regulator technical working group. A total of 671.9ML was extracted during the test period.

What did the results demonstrate?

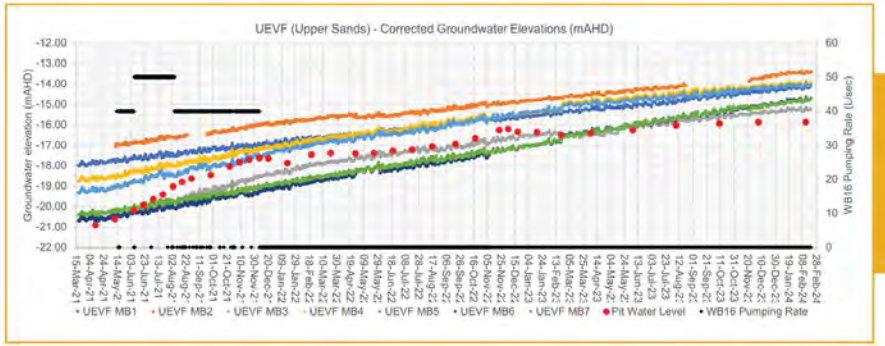
Science-based data collected throughout the process revealed groundwater dependent ecosystems, including the Anglesea River were not adversely impacted as a result of the pumping.

While the groundwater pressure reduced as expected in the UEVF lower sands, there was no impact in the UEVF upper sands or the shallow aquifer systems.

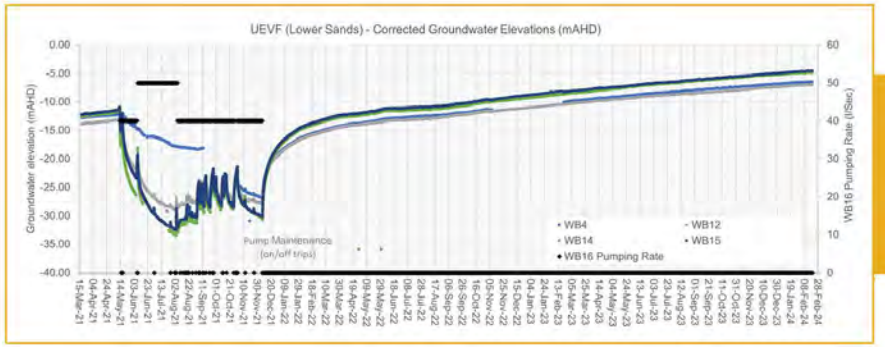
WB16 pumping bore | UEVF/DBG monitoring bore | Discharge location



Groundwater level trends in the DBG/PWT aquifer (5-50m) shows response only to natural climate variations and no impact of pumping



Groundwater level (pressure) trends for the upper part of the UEVF aquifer (40-140m) show no impact of pumping



Groundwater level (pressure) trends for the lower part of the UEVF aquifer (200m) show declines as modelled

Groundwater Model

What is it?

The model allows Alcoa to examine how groundwater systems respond to different stressors and predict what may occur under future climate conditions. It is a mathematical estimation of how groundwater flows through rocks and sediments, and provides a forecast range of estimates (called uncertainty) based on running the model hundreds of times using different realistic parameters.

The model was reviewed by the Inter-Agency Group comprising DEECA, SRW and DJPR-ERR, and was supported by a Technical Review Panel consisting of independent experts from a wide range of disciplines including geology, hydrogeology, modelling, geochemistry, and ecology.

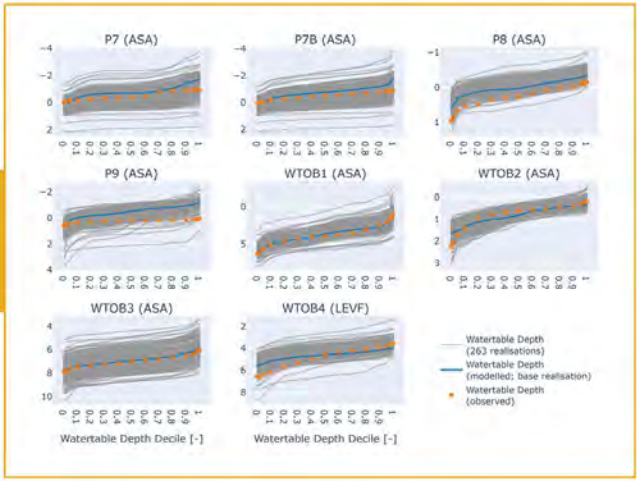
Initial modelling suggests there is a low risk of adverse impacts to groundwater dependent ecosystems, including the Anglesea River.

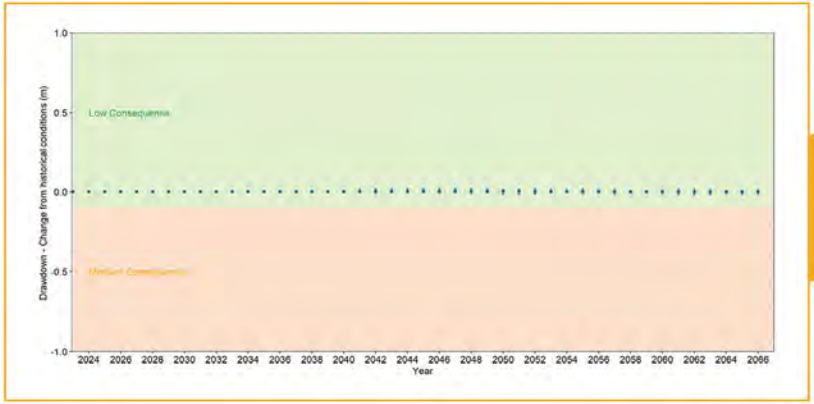
The model is one of many tools including the hydrogeological model, actual historical data, independent technical studies and groundwater pumping tests, used to help understand potential risks to groundwater dependent ecosystems, including the Anglesea River.

The model has been developed using:

- Data from more than 140 groundwater monitoring bores
- Data from six stream gauges
- Findings from historic and recent pumping tests
- Long-term climate data
- Recovery data obtained since Alcoa ceased pumping in 2016

Example of model calibration at observation bores





Groundwater level impact (WTOB1 - ASA)

What a potential application might look like

Mine water filling strategy figures

Alcoa are considering applying for a licence amendment with Southern Rural Water for the extraction of up to 1.5 gigalitres per year, for approximately 10 years.

Applying the precautionary principal, this is a conservative approach, being less than 40 per cent of the historical extraction rate.

Mitigating risk

Alcoa would expect any future licence to have specific volume and extraction limits, and a variety of stringent and standard conditions.

To further mitigate any risk to the environment, as part of any application Alcoa would also propose an adaptive management approach which would include:

- A documented water management and monitoring plan
- Ongoing, comprehensive monitoring of all available bores across all aquifers
- Multiple bores (~30) in various aquifers selected as dedicated monitoring and/or trigger bores
- Nominated trigger bores with defined water level and/or water quality triggers and contingency actions (including cessation of extraction) in the event of a trigger exceedance
- Sharing of monitoring results with community and relevant stakeholders

Monitoring infrastructure

2021 pumping test monitoring and trigger bores

View of the mine pit across completed top soil revegetation works

Alcoa's understanding of the river

Anglesea River was originally named Swampy Creek, and was changed in 1884 so as to not discourage tourists from the area[1].

Salt Creek and Marshy Creek are historically ephemeral waterways - meaning they do not flow all year round, only when the prevailing conditions allow.

Anglesea River has historically seen periods of sustained low flows, including pre-Alcoa in the 1930s and 1950s[1].

Both Anglesea River catchments have high levels of naturally occurring acid sulphate soils[2].

The lower Anglesea River appears to have historically acted in a more estuarine fashion than it does today.

In the mid-1960s Alcoa diverted the last two kilometres of Salt Creek around the mine into a clay and concrete lined diversion channel.

During operation Alcoa extracted up to 4 gigalitres per annum and discharged approximately 4.5 ML/day of pH 7 to 8 water into the Anglesea River. During low flow periods, this constituted a major portion, if not 100 per cent of flow inputs to the estuary.

There is an absence of continuous, historical actual river flow and water quality data, and little to no data before 1969.

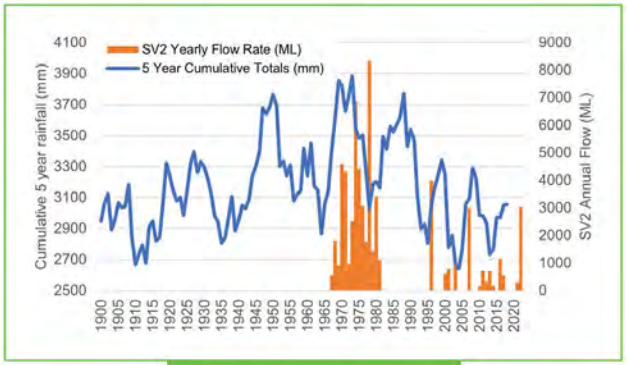
There has been numerous historical attempts to sandbag the mouth of the river, including the creation of a weir wall in 1975, 'to keep the river at a constant level'.

Coogoorah Park was created in 1983 as part of the lower Anglesea River, increasing its volume and adding a potential acid sulphate risk.

The region is going through a long-term drying cycle, using the annual rainfall/deficit versus the long-term average rainfall.

Two of the three driest five-year periods in the last century have occurred since 2006, and the two wettest five-year periods in the 1970s[3].

River flow is not just about how much rainfall, but also about when it rains and the prevailing conditions.



Rainfall and surface water relationship

Annual rainfall surplus/deficit[3]

Appendix 3 | Facebook and Instagram campaign

Off-Page Social Media Campaign

Overview

Objective: deliver an off-page targeted social media campaign to drive awareness about the three upcoming open-house community information sessions being hosted in Anglesea over May and June:

- **Campaign objective**: increase awareness about the information sessions
- **Conversation location**: https://sway.cloud.microsoft/qieBQ1ohsjXPvUWs?ref=Link
- **Channels and delivery**: deliver across two channels: Alcoa Australia Facebook and Instagram
- Campaign to target selected postcodes from Friday 17 May – Friday 24 May

Creative: 3 x animated ads utilising brand campaign imagery

- Water pump imagery
- West wall imagery
- Aerial imagery
- Animated graphics designed to suit all required ad specs for multi-platform ad delivery including feed ads, story/reel ads and right column graphics

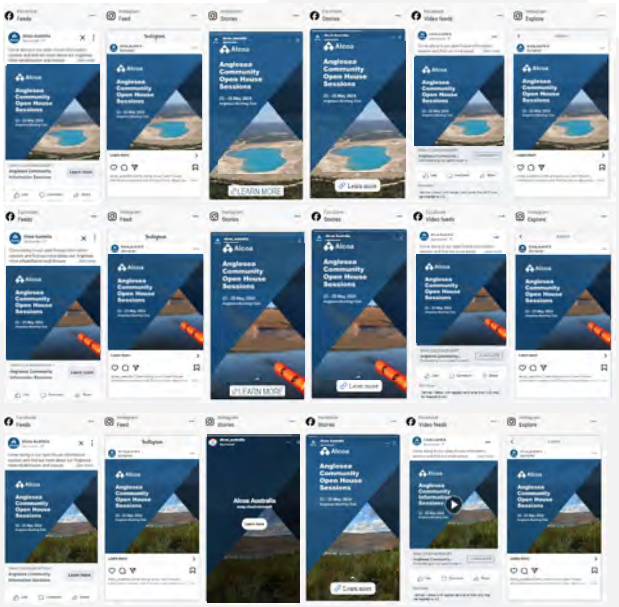
Audience: Targeting Anglesea postcode

- Anglesea 3230 and Aireys Inlet 3231

Content placement

Social media touchpoints and opportunities

- **Each advert to be displayed in 21 placements across:**
  - Facebook feeds
  - Instagram feeds
  - Facebook marketplace
  - Facebook video feeds
  - Instagram explore
  - Instagram explore home
  - Facebook Business explore
  - Instagram stories
  - Facebook stories
  - Instagram reels
  - Facebook reels
  - Facebook in-stream for Videos
  - Facebook Ads on Facebook Reels
  - Instagram Ads on Instagram Reels
  - Facebook Search results
  - Instagram Search results
  - Audience Network: native, banner and interstitial (apps and sites)



Ad results - summary

Off-page campaign performance overview

- The off-page campaign had a performance target to ensure it met the main goal of boosting awareness of Alcoa's Anglesea Community Open Sessions:
  - **Performance goal**: maximising total reach and number of impressions of ads
- The campaign, made up of three ad sets targeting the specified postcodes Anglesea 3230 and Aireys Inlet 3231

- In total, the campaign received close to 14,000 impressions, and reached an audience of just over 3,800. This a strong result considering the total audience size of the campaign sit within 5,000 – 5,300.

METRIC	RESULTS
Reach *Number of accounts/users who saw content at least once.*	3,819
Frequency *The average number of times each account saw your ad.*	2.8
Impressions *Number of times your ads were on screen.*	13,945
All Clicks *The number of clicks, taps or swipes on your ads.*	103
Link Clicks *The number of clicks, taps or swipes within the ad that led to advertiser-specified destinations*	32
Engagements *Number of actions people take involving ad.*	732

Ad results - audience

Off-page campaign gender breakdown

Gender breakdown

	Reach	Impressions	Engagements
Male	2,100	7,810	395
Female	1,681	5,996	330
Uncategorised	38	139	7

Age breakdown

	Reach	Impressions	Engagements
18-24	840	3,207	102
25-34	954	3,765	95
35-44	575	1952	124
45-54	458	1813	118
55-64	496	1674	117
65+	496	1534	176

Findings

- The campaign was well-received by both the male and female audiences. The budget optimsation tool prompted an increase in budget allocation to the male-owned accounts to effectively hit the 'reach' targets set for this campaign
- Findings are a true reflection of current Facebook user statistics (as of January 2024 via Statistica) with men between the ages of 25 and 34 years making up the largest audience (20%)
- Interesting to note that users between the ages of 25 and 34 saw the campaign the most but those in the 65+ age bracket were the most engaged. This reflects the Australian Bureau of Statistics population census results of Anglesea that details people between the ages of 60 to 80 make up the largest portion

https://abs.gov.au/census/find-census-data/quickstats/2021/SAL20046

Alcoa Anglesea Open House Sessions

Community and Stakeholder Feedback Questionnaire

Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

- [x] Yes
- [ ] No

Has this session informed you about what viable options there are to fill the mine pit?

- [x] Yes
- [ ] No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

- What will happen to the freehold land.

Alcoa

Alcoa Anglesea Open House Sessions

Community and Stakeholder Feedback Questionnaire

Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

- [x] Yes
- [ ] No

Has this session informed you about what viable options there are to fill the mine pit?

- [x] Yes
- [ ] No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

① Despite the huge effort obviously made it is still difficult for even informed locals to understand.

② The complexities & variables are huge

③ I believe most residents who bother to come really want to know only "how can we have our river back to health". Alcoa seems keen this to be ongoing as the river is a separate issue from the filling of the pit.

Alcoa

Alcoa Anglesea Open House Sessions

Community and Stakeholder Feedback Questionnaire

Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

○ Yes ○ No A little.

Has this session informed you about what viable options there are to fill the mine pit?

○ Yes ☑ No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

[redacted] I found the information well presented but difficult to understand as it is very complex and a lot to take in.
I'll read up and try to absorb the information
(I took photo's)

☑ Yes ○ No

Has this session informed you about what viable options there are to fill the mine pit?

☑ Yes ○ No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

No.

Over the years since the mid 1960's I have supported everything Alcoa has done for the town. From employment of locals to support of almost all local clubs and organisations around town in the form of donations. Their commitment to rehabilitation of the mine site to demolition of power station and the ongoing attention to water mine filling, reshaping the mine and mountaining the nature drainage has been commendable.

(✓) Yes ( ) No already informed

Has this session informed you about what viable options there are to fill the mine pit?

( ) Yes (✓) No would like to see more recent modelling

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

Feels like a lot of people have other plans of their mind, e.g. cost of living, accomadation, climate change

"damge is done, I'm only here because I care about the river"

"concentrated sulphar fall-out in the mine"

*Feels there has been a lack of responsibility on behalf of many parties, including government

Has this session informed you about what viable options there are to fill the mine pit?

○ Yes ⊘ No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

(1) The presentation of information was very complex and difficult to understand, even as an experienced scientist, so probably quite inaccessible to a lay person.

(2) The hydrogeologist hired by Alcoa is pushing the climate change argument for the state of the river which is unsubstantiated.

(3) Warren Sharpe stated that there was no engineering advantage in rapidly filling the mine void, so on this basis should be left, rather than further depleting the aquifer.

Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

○ Yes ○ No ⊗ A little bit

Has this session informed you about what viable options there are to fill the mine pit?

○ Yes ⊗ No

Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

The information provided was relatively complex and would require further examination to fully understand Alcoa's arguments - too much information - too little time. I am most concerned that Alcoa is suggesting that climate change is the major driver of reduced flows and acidity in the Anglesea River, without considering the impact of the mine void (and cone of depression) on the river.

Our major concern as residents is that pumping may lead to further depletion of the overlying river catchment.

There is certainly no benefit to the river and catchment by Alcoa pumping water from the VEA, the argument that rapid filling of the void will be of environmental value to the area is spurious, as it will not provide any ecological benefits at all.

Even Warren Sharpe also [illegible] indicated that rapid filling of the void is not necessary from an engineering perspective as the walls are stable.

I feel that it environmentally irresponsible of alcoa to resume pumping from the VEA rather than allowing the aquifer to replenish and reach its natural levels

I see no point in pumping to fill an un-natural, toxic, acidic ditch.
