Executive Summary

Alcoa are seeking to obtain approval from Southern Rural Water to reduce the existing Groundwater Licence (BEE029662), from 4000 ML/yr to 1,500 ML/yr (for 10 years) and amend its use to allow this groundwater to accelerate filling of the former Anglesea coal mine to help achieve the draft Mine Rehabilitation and Closure Plan (MRCP) objectives.

To ensure the reduced and amended allocation poses no unacceptable risks to the environment that may rely on groundwater, a groundwater impact assessment (GIA) has been completed in accordance with Section 51 and Section 59A of the *Water Act (1989)* and EPA Victoria Publication 688.1 (2022) Hydrogeological assessment guidelines for groundwater quality.

The GIA considers multiple sources of data and lines of evidence including:

- Review of multiple independent technical assessments conducted in the region relevant to potential groundwater impacts (**Section 2.3**);
- Detailed assessment of long-term water level, water quality, climate and surface water flow observation data from more than 130 groundwater monitoring points and available surface water flow sources (**Section 4**);
- Significantly improved Conceptual Hydro-geological Model for the Alcoa area of interest which has been subject to and endorsed by the regulator Inter Agency Group appointed independent Technical Review Panel (TRP); (**Section 6** and **Appendix A**);
- Predictive tools such as the updated 2024 Anglesea Groundwater Numerical Model, which has also been subject to and endorsed by the TRP comprised of independent experts from a wide range of fields including geology, hydrogeology, modelling, geochemistry, and ecology. The TRP was selected by an Inter Agency Group, representing the Water and Catchments Group of DEECA, Earth Resources Regulation, and Southern Rural Water (**Section 7** and **Appendix B**);
- Hydrogeological risk assessment including for proposed Alcoa groundwater extraction, including applying the relevant medium and high climate change models (**Section 8**);
- The results of a purpose designed groundwater pumping test completed in 2021 that was subject to significant regulatory oversight (**Appendix D** of **Appendix A**); and
- The feedback from on-going and recent community engagement processes and events (**Section 2.4**).

The GIA is based on long term water level, water quality, climate and surface water flow observation data that has formed a well-established and understood baseline of conditions across the catchment. This historical data also spans across numerous climatic and external groundwater stress periods that have operated at much greater stresses (i.e. higher groundwater extraction rates) than what is being proposed as part of the amended application. The hydrographic analysis (pre and post these stresses, including 9 years of continuous groundwater level observation data since Alcoa ceased UEVF extraction (2015)), show no observable or statistically significant trends which can be identified in the existing groundwater observation network for the shallow Alluvial Swamp Aquifer (ASA), indicating groundwater behaviours in these shallow aquifers have remained relatively consistent with seasonal variations, with climate (as indicated by rainfall) influencing its behaviour.

This is also supported by other observations as outlined in the hydrogeological conceptual model, such as:

- Groundwater mounding in the ASA following significant rainfall or flow events is not observed from daily monitoring groundwater data adjacent to the alluvial creek systems near the former power station, indicating in this area these leakage rates from the ASA to underlying aquifers is not a significant migration pathway.
- Isotope analysis of residual water pools in the ASA (or creek systems) supported evidence that these pools were not supported by groundwater; rather, they are surface water fed located in areas of low potential evapotranspiration.
- Groundwater level trends in the ASA are similar regardless of the underlying Upper Eastern View Formation (UEVF) potentiometric surface being higher or lower than the water table in the ASA.
- The Anglesea River has experienced low pH events prior to Alcoa activities at a sampling point located just upstream of the former Power Station with this area consistently recorded pH between 2.5 and 4 since 1967.
- Continuous pressure monitoring data from Vibrating Wire Piezometers (VWPs) from above the dewatered main coal seam (in the Demons Bluff Group) from 1999 to 2011 as well as those installed around the former power station from 2006 show no response to UEVF groundwater extraction.

From May to December 2021, Alcoa also conducted a groundwater pumping test as approved by Southern Rural Water (SRW) with close oversight by a cross regulator Technical Working Group (TWG) including SRW, ERR, EPA, DELWP and CCMA & Barwon Water. The purpose of the pumping test was to further assess potential risks associated with groundwater extraction and placement into the mine as part of the filling strategy. The ongoing results of the test, shared with regulators and community alike, importantly showed no adverse impact on groundwater dependent eco-systems including the Anglesea River.

In addition, the significant amount of available geological and hydraulic data and the responses to historical stresses has led to the development of a robust numerical model (2024 Anglesea Groundwater Model; also referenced herein as GHD 2024). The development of this model (including the hydrogeological conceptualisation) has been subject to and endorsed by a State appointed Technical Review Panel (TRP) comprised of independent experts from a wide range of scientific fields. This approach ensures that the model represents current best conceptual understanding, technical practice, and meets the model defined objectives (e.g. used to conservatively predict potential impacts such as lowering of water tables or impacts to stream flows as a result from extraction under certain climate models).

In using this model, and considering Alcoa's proposed amended groundwater entitlement, the 2024 Anglesea Groundwater Model predicts the following:

- The mine void can be filled decades faster than what it would naturally take, meaning the environmental and potential social and economic benefits of a rehabilitated safe and stable (steady state) landform can be realised much sooner.
- In the regions where Alcoa's pumping is modelled to have the greatest potential impact to the Alluvial Swamp Aquifer (ASA), that is the aquifer underlying the surface water marshlands, leakage rates as a result of the proposed groundwater entitlement are modelled to potentially increase by only:
    - 0.43 mm/yr along the ASA mid-section of Salt Creek; and
    - 0.75 mm/yr for along the ASA mid-section of the Anglesea River.

- Once the void is full of water, leakage from the shallow surrounding local aquifers into the void would cease meaning this recharge will remain in these aquifer systems for longer and not be lost to the mine void.
- Pit water migration was modelled by adding 300,000 particles in the waterbody and simulating movement across 150 model realisations, totalling more than 45 million particles. Of these, only 35 particles indicate a particle of water may extend past Alcoa's lease boundary. Furthermore, at the end of the model simulation, these particles are starting to turn back towards to mine water body
- Under a medium and high climate change scenario, the median water table drawdown at all observation bores within the ASA have modelled drawdown <0.1m resulting in the lowest consequence level of impact to GDEs as defined by the 2015 Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems.
- In areas where GDEs have no shallow alluvial observation bores, that is the marshlands in the alluvial valleys, under both climate change scenarios (high and medium), median drawdown is modelled to exceed 0.1m in only two small tributaries of the mid reaches of the Anglesea River. In this area, over the last 14 years, the potentiometric surface of the UEVF is higher than the water level in the ASA.
- Median drawdown for the alluvial swamps located along Salt Creek do not exceed 0.1m. This is an important observation as by reference it implies historical pumping and the reduction in surface water flow observed between the two periods, 2010 to 2023 and 1968 to 1981 are not strongly correlated.
- When considering model uncertainty and likelihood, e.g. the P10 uncertainty limit which takes into consideration 90% of the 150 model realisations, under a medium climate change scenario, the maximum potential drawdown at any shallow alluvial observation bore is 0.11m. This increases to 0.22m under a high climate change scenario. It is important to note that historical groundwater monitoring at this location shows no evidence of historical UEVF pumping related impacts (despite larger historical extraction rates). This modelled drawdown is also much less than the annual variability observed in groundwater levels.
- The modelling also predicts no reduction in annual no flow days at end of catchment gauging stations SV2 and AV2, and the seasonal variability of the ASA water table (WTOB1 and WTOB2) relative to the historical period do not result in any moderate or high consequence impacts or lead to an increased risk of acid generating events.

Despite the overall low risk and conservative approach (for example the numerical modelling takes into consideration a wide range of uncertainty by treating the P10 to P90 model outputs as the same likelihood to occur), as well as the effects of climate change, it is recognised that the ASA is a sensitive receptor, and that groundwater extraction does present a risk (albeit low as described above). Therefore, to monitor for potential risks, an adaptive monitoring and risk mitigation plan is proposed to form part of conditions imposed on any groundwater entitlement.

When cumulative impacts are considered (climate, Barwon Water potential Bulk Entitlement from LEVF, and Alcoa proposed amendment from UEVF), some increased risks to GDEs, surface water flows and potential acid generating events are forecast with these largely driven by climate impacts. While the licencing and approval of a LEVF BE is outside the control of Alcoa, it is nevertheless included for completeness in this GIA as directed by Southern Rural Water. For reference, the LEVF BE is currently going through a separate review by Barwon Water and Alcoa understands that it will be subject to approval by the Minister for Water under the Water Act 1989. Cumulative risks may also be managed via the inclusion in any entitlements (Barwon Water and Alcoa) appropriate adaptive monitoring and risk mitigation plans as described above.

Alcoa also recently conducted three open house style community engagement events seeking feedback on a potential Alcoa groundwater application and was provided with good support summarised as follows:

- 88 per cent of feedback received indicated that attendees felt they better understood the draft Anglesea Mine Rehabilitation and Closure Plan.
- 86 per cent of the feedback received indicated that attendees felt informed about what viable options there are to fill the mine pit.
- The majority of feedback (56 per cent) was assessed as being either neutral in tone or positive (32 per cent), with only 14 per cent assessed as negative.

On the basis of all of the above, Alcoa is now seeking a groundwater license amendment to enable the extraction of up to 1.5 gigalitres per year (GL/yr) for a period of 10 years (with appropriate conditions) to enable the accelerated filling of the mine pit consistent with the draft MRCP. As part of any amended groundwater licence, Alcoa proposes that one of the key conditions would include an updated adaptive management and monitoring plan, including trigger levels and actions, which must be provided to and accepted by SRW prior to any extraction occurring under this licence.

1 Introduction

Alcoa was licensed to extract 4,000 megalitres/year (ML/yr) from the Upper Eastern View Formation (UEVF) under Licence Entitlement ID BEE029662 up until 30 June 2024, however this licence does not permit the use of groundwater for the purpose of filling the former mine void.

Extensive investigations into possible options to fill the mine void as part of mine rehabilitation and closure planning has confirmed that only two options remain feasible, the use of UEVF groundwater (over 7-10 years) or via a natural fill (expected to take many decades). As such, Alcoa seeks to fill the mine void utilising groundwater from the UEVF. This "accelerated fill" strategy is consistent with the 'draft' Mine Rehabilitation and Closure Plan (MRCP) submitted to Earth Resources Regulator (ERR) in September 2017.

Left to fill naturally, it is estimated that the mine void will take many decades to fill. By accelerating the mine void filling, broader benefits can be realised sooner, such as:

- Completion of the Anglesea mine rehabilitation and closure and return of the Crown land area to the State and to the community in a timely fashion, and many decades quicker than otherwise achievable.
- Shallow groundwater systems in the vicinity of the mine void achieves steady state decades quicker than otherwise.
- Assists with geotechnical stability, which comprises a safe and stable landform (e.g., risk of floor heave is reduced).
- A large permanent water source is available to support the long-term Lower Anglesea River management strategy at the discretion of the State.
- An emergency supply of water which is of equivalent water quality, if not better than some existing surface water conditions, will be available to help mitigate bushfires.

Potential economic benefits including significant long term employment opportunities to the region could be realised as part of potential eco-tourism opportunities and projects. These types of projects would create significant sustainable community amenity and act as a catalyst for an estimated potential regional economic benefit of more than one billion dollars over a ten-year period (e.g. the Eden Project).

Alcoa is now seeking a groundwater license amendment to enable the extraction of up to 1.5 gigalitres per year (GL/yr) for a period of 10 years (with conditions) to enable the accelerated filling of the mine pit consistent with the draft MRCP. In the interests of exercising the precautionary principal, Alcoa is proposing a lower rate of extraction than compared to historical, recognising that some in the community have concerns with groundwater extraction, and to also to ensure that any risks to groundwater dependent ecosystems (GDEs) and the Anglesea River are minimised or avoided.

As part of the proposed license amendment, Alcoa proposes to adopt an adaptive management and monitoring plan that includes the establishment of agreed early intervention groundwater monitoring triggers, actions, contingencies and reporting – similar to that adopted for the 2021 Alcoa groundwater pumping test, and also used by Barwon Water.

1.1 Background

The former Anglesea Coal Mine (referred to as “the mine”) is located approximately 3 kilometres (km) northwest of the Anglesea township in Victoria. Adjacent to the mine is the former Anglesea Power Station (referred to as “the former power station”).

Alcoa were licensed to extract 4,000 ML/yr from the UEVF under Licence Entitlement BEE029662 (also referred to as a Groundwater Licence or a Take and Use Licence) until 30 June 2024. The purpose of use is permitted as industrial or commercial use, as well as industrial and stock but is subject to the groundwater being used on Allotment 64D of the former power station site only (Block 1-4 on **Figure 1-1**).

Filling the mine void with groundwater, which is not located on Allotment 64D, remains a key enabler for the draft MRCP as submitted to ERR in September 2017.

During the progressive rehabilitation works over the past nine years, the mine void water level has been slowly rising as forecasted largely as a result of natural groundwater recovery, direct rainfall, and local catchment runoff only with a small amount also added as part of the 2021 Alcoa groundwater pumping test. Using the latest predictions from the 2024 Anglesea groundwater numerical model (referred to herein as the Alcoa Groundwater Model; refer **Section 7**), it is estimated that allowing the mine void to naturally fill to a height of +4.0 metres Australian Height Datum (m AHD) will take many decades (refer to **Section 7** for further discussion on fill time uncertainty). The fill height of +4.0 m AHD has been defined in the draft MRCP as full, noting the mine void overflow to Marshy Creek is at an RL of approximately +10 m AHD (equivalent volume of more than 6 Gigalitres (GL)).

Alcoa submitted a Groundwater Impact Assessment (GIA) in September 2020 evaluating risks to both the environment and third-party users associated with a proposed 12-month groundwater pumping test of the UEVF aquifer. In October 2020, Southern Rural Water (SRW) issued an amended groundwater licence including an Addendum (LH1575619) to the Licence Entitlement BEE029662 and Licence to Operate Works WLE0351661.

The amended groundwater licence permitted a 12-month groundwater pumping test and extraction of up to 1.5 GL of groundwater from the UEVF ‘for the purposes of discharging groundwater to the mine void as part of the amended licence’.

Alcoa subsequently commenced a groundwater pumping test of the UEVF aquifer on 13 May 2021 to enable further investigations of groundwater use. The pumping test was paused on 8 December 2021 after a total of 671.9ML was extracted, representing approximately 44 percent of the licensed volume. The findings of the first 6-months were reviewed during this period, with data used to inform the development of the 2024 Anglesea Groundwater Model (refer **Section 7**) and also an updated UEVF Conceptual Hydrogeological Model (CHM).

It was subsequently determined by SRW, based on advice provided by an Inter-Agency Group (IAG – DEECA, SRW, ERR) selected Technical Review Panel (TRP) that the second 6-month period of the pumping test would not provide any additional information to further constrain data gaps and uncertainty to support the development of the CHM and Anglesea Groundwater Model, required for the potential future application for licence amendments.

The works to update the UEVF CHM for the Alcoa area of interest were completed by EHS Support for Alcoa during 2022, with independent peer review provided by the TRP, culminating in the update being approved by TRP on date 8 February 2024. The UEVF CHM is provided in **Appendix A**.

The works to update the 2013 Anglesea Groundwater Model were completed during 2022 and 2023 in conjunction with Barwon Water, with independent peer review provided by IAG/TRP, culminating in the updated 2024 Anglesea Groundwater Model being deemed '*fit for purpose for conducting predictive modelling to inform Barwon Water's Bulk Entitlement review process and Alcoa's mine rehabilitation strategy and groundwater assessment for a groundwater licence application'* by the IAG/TRP on February 8th, 2024 (**Appendix B**).

1.2 Purpose/Objective

The purpose of this report is to provide a groundwater impact assessment (GIA) to support a proposed amendment of Alcoa's groundwater licence (BEE029662), from 4000 ML/yr to 1,500 ML/yr (for 10 years).

The use of this groundwater is to enable faster filling of the mine pit void consistent with the Mine Rehabilitation and Closure Plan providing a long term safe, stable, and sustainable landform. The accelerated filling will create a water body in 7 to 10 years in contrast to natural filling which would take many decades.

The mine pit water body is not intended to provide environmental values such as direct contact recreational uses and flora/fauna habitat support which are not complimentary to the background surface waters and local catchment. The water body does however have the future potential to provide non- direct contact recreational aesthetic enjoyment such as visual appearance and bird watching from the surrounding Anglesea Heath.

This report has been developed in accordance with EPA Victoria Publication 688.1 Hydrogeological assessment guidelines for groundwater quality and Section 59A of the *Water Act* (1989) to provide a GIA to support an amendment to Alcoa's Licence Entitlement to Take and Use groundwater from the UEVF, seeking to permit use of this groundwater to accelerate filling of the mine void.

Furthermore, to align with the precautionary principal and to satisfy Section 40 of the Water Act 1989, the results presented in this application err on the side of conservatism as the numerical results which form the risk assessment have isolated Alcoa's pumping impact from other cumulative impact contributors such as Barwon Waters Bulk Entitlement and climatic factors, also presented in this application. By using this approach, the modelled outputs are more conservative (i.e. Alcoa's numerical impact is likely greater than may be realistically observed, thus satisfying Section 40 of the Water Act 1989). This is further discussed in **Section 0**.

2 Site Overview

2.1 Site Location

The former Anglesea Coal Mine is located approximately 3 km northwest of the Anglesea township in Victoria. Adjacent to the mine (to the west-northwest) is the former power station. The general site layout is shown in **Figure 2-1** and its regional location is shown **Figure 2-2**.

2.2 Site History

2.2.1 Pre 1960

Roche Brothers commenced open cut mining operations on the Anglesea coal deposit in the late 1950s. Around the same time, the concept for an aluminium smelter at Point Henry was developed (by Western Aluminium NL which became Alcoa of Australia (Alcoa) in 1961) about 7 km from Geelong, with feedstock alumina to be shipped from Western Australia.

The concept envisaged that the smelter would be supplied with approximately 70 percent (at that time) of the required electricity from a new generating station to be located at Anglesea and fuelled from the adjacent brown coal mine. Drilling was undertaken in 1960 in the Anglesea area which revealed a main coal seam mining area adjacent to the lower seam being operated by Roche Brothers. Assessments at the time showed a coal deposit of about 120 million tonnes, compared with approximately 30 million tonnes assessed by Roche Brothers.

2.2.2 1960-2016 (Mine Operation)

The mining rights were obtained by Alcoa from Roche Brothers at Anglesea, and on 22 November 1961 the *Mines (Aluminium) Agreement Ac*t was passed, providing Alcoa the rights to explore and mine over 7,350 hectares of leasehold land largely to the northwest of Anglesea, including the area being mined by Roche Brothers. Power station construction began in 1965 with the first power produced in March 1969.

The drilling program revealed that the original mining by Roche Brothers was in a lower seam to the west of the main upper seam. A new mine was resultingly opened adjacent to and expanding away from the power station site. Overburden removal was initially used for backfilling the old Roche Brothers open cut mine and to facilitate rehabilitation of the entire Roche Brothers site. **Figure 2-4** shows the progressing mining extents and **Figure 2-5** shows progressive backfilling extents.

Alcoa began to pump groundwater from the UEVF in 1969 to support the then newly constructed operation of the power station and mine. A series of boreholes from 1964 were drilled by Alcoa that were licensed to extract groundwater from the lower aquifers within the UEVF (**Figure 2-6**). These extraction bores extracted groundwater used for process and cooling water for the power station, with surplus (treated) process water directed to an Environment Protection Authority (EPA) licensed discharge point, providing baseflow and pH ~7-8 water to the Lower Anglesea River. Daily extraction rates from these bores were collectively around 4.5 ML/day. Prior to this licenced discharge, the pH of surface water upgradient of the former power station site has consistently remained acidic (**Figure 2-3**) due to natural catchment processes.

The historical groundwater extraction bore network at the time comprised bores WB9, WB10, WB13, WB14, WB15, WB16, and WB17 (**Figure 2-6**). Some of these bores (WB9, WB10, WB13, and WB17) have since been decommissioned (refer **Section 2.2.4.4**). In addition to the extraction bores, Alcoa undertook mine dewatering activities directly from the mine pit. The mine pit, which is excavated to a maximum depth of approximately -45 m AHD, was dewatered from a progressively moving sump positioned at the lowest part of the operational mine at an extraction rate ranging between 1 to 1.5 ML/day when pumping. This pumping was conducted intermittently, approximately 60 percent of the time (based on in-flows and rainfall).

The majority of groundwater extraction ceased in 2015 following the shutdown and closure of the Anglesea power station and mine on August 31st, 2015, with final extraction ceasing on March 1st 2016, after Alcoa provided ongoing support, such as maintenance of environmental flows, to the Anglesea River at the request of the State.

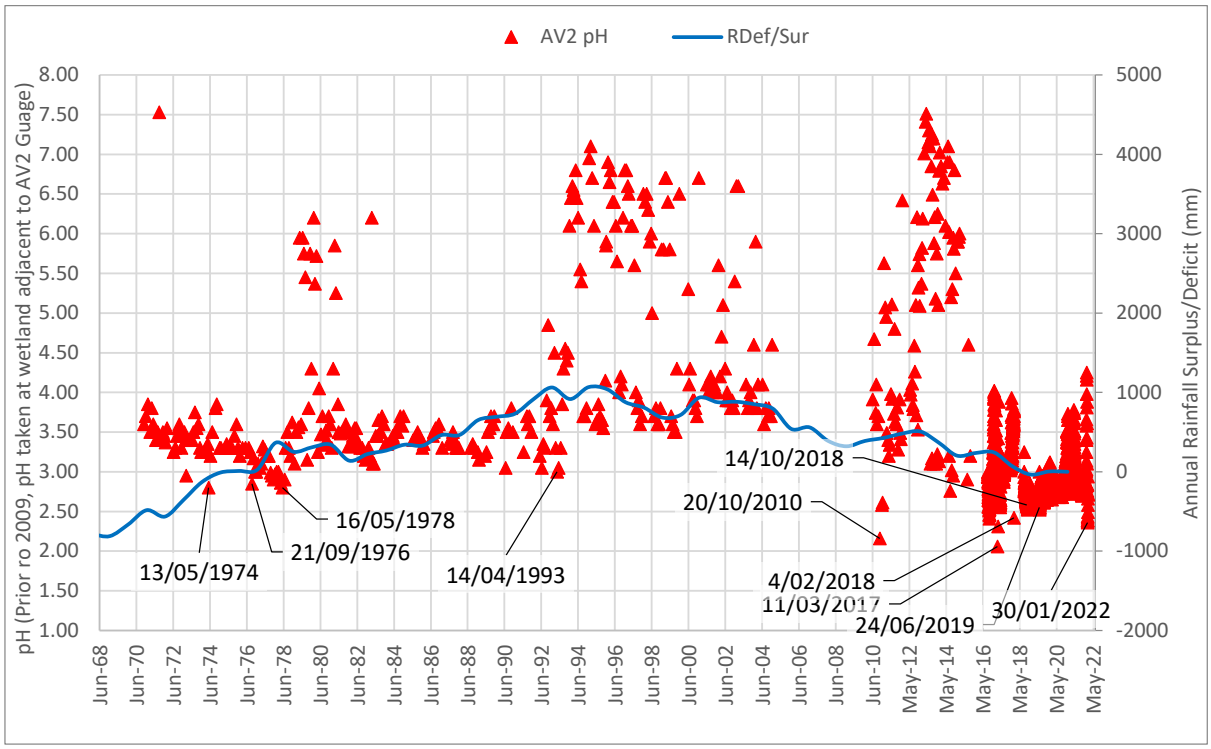

Figure 2-3 Historical pH Upgradient of the Former PowerStation

2.2.2.1 Historical Ash Management

The former power station at Anglesea used coal from the former open cut brown coal mine (adjacent to the power station) to generate electricity for the aluminium smelting facility in Point Henry, Geelong. The power station started generating electricity in 1969 and closed in 2015. Approximately 1 million tonnes of brown coal was consumed by the power station each year (GHD, 2012). The ashing system was used to collect, convey, and dispose of the ash generated within the furnace and from the precipitators at the Alcoa Anglesea former power station. The coal at Anglesea contained on average between 2 to 4 percent ash, which is a by-product of the coal combustion process. Some of the ash was collected in the furnace bottom hopper, while the fly ash was entrained in the flue gases. The fly ash comprised a greater proportion of the total ash. The electrostatic precipitators collected the fly ash from the gas stream before the atmospheric dispersal of gases via the stack. The bottom ash from the furnace was sluiced away by water from the ash tank and the fly ash was removed by a pneumatic system. The combined furnace ash and fly ash was then transported by the water sluices through piping to the northern most Ash reclamation Pond shown on **Figure 2-1**.

Leached ash from this pond was periodically removed and dried. With the excavated leached ash was then deposited in the mine pit and incorporated into the general overburden backfill process as per the historical Mine Work Plan endorsed by ERR.

When the former Power Station was closed, the final dried leached ash was progressively tipped by truck and deposited in the consolidated leached ash (CLA) area within the south-eastern corner of the former coal mine, refer on **Figure 2-1**. This was permitted in accordance with the Mine Work Plan endorsed by Earth Resources Regulation (ERR) in September 2011.

The CLA material which has been encapsulated by at least 1m of rolled clay, will be inundated and submerged by the developing water body. To ensure Alcoa meets its general environmental duty (GED) by demonstrating that risks to the environment (including surface water and/or groundwater) remain low as far as reasonably practical in both the short and long term regardless of the water body fill strategy, a detailed technical review and risk assessment was undertaken. This review which been independently peer reviewed by BlueSphere is attached as **Appendix C** and demonstrates risks remain low.

Finally, when reviewing **Appendix C**, the reader should also review **Section 7.3.5**, which provides information about pit water and aquifer interaction.

2.2.3 Post-2008 – Barwon Water Groundwater Extraction

The Barwon Water Anglesea Borefield (referred to as the Anglesea Borefield) is used to extract groundwater from the Lower Eastern View Formation (LEVF) in the Jan Juc Groundwater Management Area and contains seven production bores that are licensed to extract a maximum of 40 ML/d, or 10,000 ML in any year, and 35,000 ML in any 5-year period. Five of the seven bores (GW1, GW 2, GW3, GW4, and GW5) are located proximal to the Anglesea mine (**Figure 2-8**).

Commissioning and testing of the bore field first commenced in October 2009 and ceased in June 2012, with a total of 7,617 ML pumped during that period. Due to low water storage levels, recommissioning of the bore field began in August 2019 to supplement the existing Greater Geelong water supply system. Between August 2019 and end of June 2020 a total of 2,177 ML was extracted from the Anglesea Borefield[1].

The Anglesea Borefield was moved into a standby maintenance mode from 1 July 2020, and has only been operated for maintenance purposes until 27 January 2022, when Barwon Water began a 6-month groundwater pumping test to inform a review of its bulk entitlement and environmental monitoring program.

A timeline of historical extraction for both the UEVF and LEVF is presented in **Figure 2-7**.

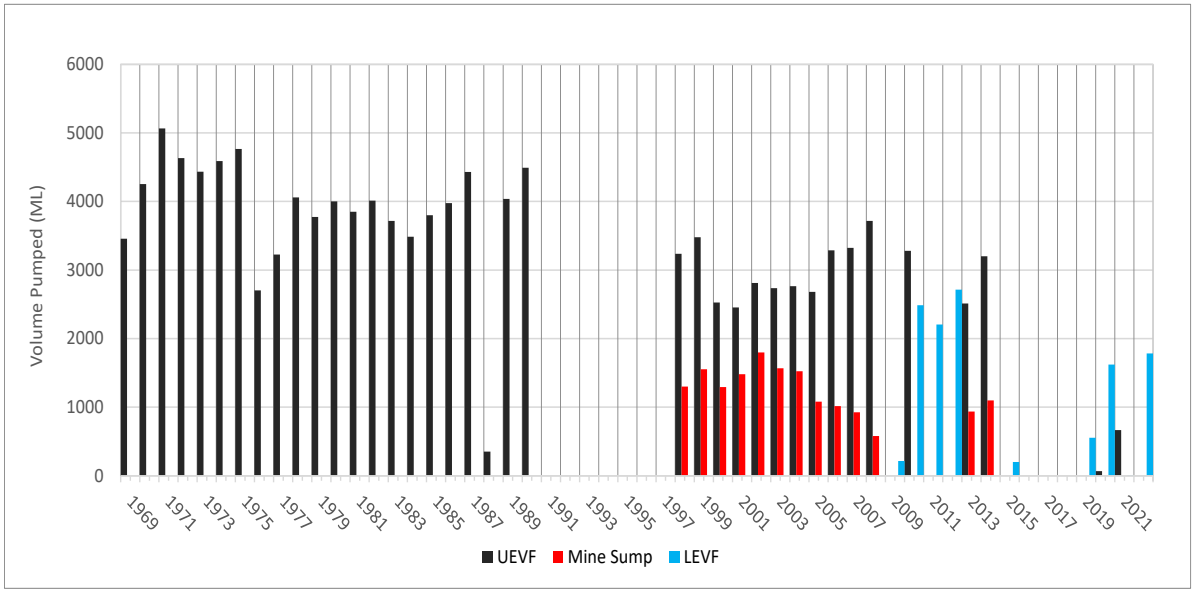

Figure Notes:
UEVF Data missing for 1991-1997, 2009 & 2011-2012
UEVF volumes prior to 1989 also include the mine sump volume

2.2.4 Mine Rehabilitation Since 2015

Following the shutdown of the former power station and mine in August 2015, detailed planning for the final closure and rehabilitation of the mine commenced including detailed technical studies and community and regulator engagement. In September 2017 a draft MRCP was submitted to ERR proposing earthworks, revegetation, and the establishment of a water body. In March 2018 a Work Plan Variation - Progressive Rehabilitation was subsequently approved by ERR approving the earthworks and revegetation works.

Major earthworks were commenced in November 2018 and completed in June 2020, including the reprofiling of the west and south slopes of the mine, the installation of surface water catchment drains at strategic points around the mine, and the relocation of part of Coal Mine Road.

Revegetation works consisted of native heathy topsoil revegetation works in 2018 and 2019 on the north and west walls, and also the establishment of a large native grassland on the south wall which was completed in September 2020. Both the earthworks and revegetation works have entered a monitor and maintain phase with active monitoring programs in place.

2.2.4.1 Installation of Groundwater Observation Bores (2020 / 2021)

During 2020 and 2021, 16 groundwater observation bores were constructed around the periphery of the mine in addition to the 71 existing Alcoa installed bores. The rationale for the construction depth and location of these bores is discussed in **Table 2-1**. The construction details and bore logs are presented in **Appendix A**. The location of these bores is shown on **Figure 2-9** and **Figure 2-10**.

Table 2-1 Rationale for Construction of New Near Mine Void Bores

Bore ID	Rationale
UEVF MB 1	The purpose for construction of these bores is to: • Obtain a greater understanding of the lithology and groundwater levels in the upper section of the UEVF. • Confirm extensiveness of the basal clay which is assumed to overlie and confine these “upper sands”. • Act as monitoring bores to monitor for potential drawdown impacts arising from the pumping test undertaken in May 2021 which could then imply drawdown from the mine pit waterbody into formation.

2.2.4.2 Catchment Drains

Important to the overall mine water balance are the installation of catchment drains to assist surface water runoff from the greater mine catchment area to be directed into the mine void without damaging the engineered slopes. Some of these drains are pictured on **Photo 2-1** and the overall layout of the drains and their supporting catchment is shown in **Figure 2-11**.

2.2.4.3 Subsidence Monitoring

From 1996 onwards the potential for subsidence has been monitored from prism and GPS pin monitoring from the south wall area of the mine; in summary, the movement that is observed during the 2000's is attributed specifically to 'relaxation' of the wall in response to actual mining operations. Relative levels typically have not otherwise moved significantly since monitoring began.

2.2.4.4 Decommissioning of Site Infrastructure

Between 1969 and 2015, Alcoa's groundwater extraction and monitoring used a series of 12 groundwater bores located across the former power station site (WB3, WB4, WB5, WB8, WB9, WB10, WB12, WB13, WB14, WB15, WB16, and WB17). During 2020 and 2021, these bores were subject to a borehole assessment program (BAP) which comprised geophysical logging (gamma and calliper) and downhole camera inspection to determine the bores condition and the reliability of the data during the pumping test. A summary of the results is presented in **Table 2-2** with the detailed results shown in **Appendix A**.

Table 2-2 Findings of Bore Assessment Program

Bore ID	BAP Assessment	Action
WB3	During the CCTV investigation the bore was confirmed to be full of sediment. The bore was cleaned out using mud rotary drilling techniques to a depth of 201 m, which is either the base of the bore or an obstruction. The drill rig could not progress past this depth. The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF and was therefore decommissioned. The bore was perforated at a depth of 195 m, 5 m above the UEVF/MEVF interface.	Decommissioned
WB4	This bore was repaired in 1977 by re-sleaving with an 8-inch casing. As part of the BAP, the drilling contractor advanced down through the bore annulus to 195m. A geophysics survey was completed, and the screened intervals were confirmed at 117 - 120 m, 161 - 164m, and 176 - 182m. It is likely that other screened intervals were installed but these could not be confirmed by the geophysics survey. A decision was made to re-sleave WB4. The re-drilling of the bore as part of the BAP was successful and lithological information and geophysical logs were reviewed to enable a suitable design. The following bore design summary is provided: • 50mm diameter screen and casing. • Screen intervals at 117-120m, 161-164m, 176-182m, 191-194m. The casing was perforated at 192.5m. • Fibre-glass casing was used from 0-117m. • Stainless steel screens and blank casing were used from 117-195m. • A sump was installed from 194-195m.	Repaired
WB5	Downhole camera confirmed that the casing had pulled apart at 86.5 m and the bore was full of sediment to 112.5m. The bore was cleaned out using mud rotary drilling techniques to attempt to reach the bottom of the bore and to confirm screen intervals. Based on the drillers observations and the geophysics survey responses, the casing was compromised at a number of depths; therefore, WB5 was confirmed to be unsuitable for monitoring or sampling purposes. The responses also indicated that the bore was only constructed to a shallow depth, around 151 m, when compared to the surrounding production bores. This bore was therefore only screened in the lower sands of the UEVF and was decommissioned appropriately.	Decommissioned
WB8	The driller confirmed that this bore had previously been decommissioned and grout was encountered at 50 m when cleaning out the bore. This bore was then decommissioned again using a grout/bentonite mix to the ground surface.	Decommissioned

Bore ID	BAP Assessment	Action
WB9	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, and was therefore decommissioned. The bore was perforated at a depth of 162 m.	Decommissioned
WB10	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, and was therefore decommissioned. The bore was perforated at a depth of 117 m.	Decommissioned
WB12	As part of the BAP, the drilling contractor had identified a number of integrity issues with this bore: • Damage to the casing at 90m and between 107m and 117m; • Significant debris throughout with a large obstruction at 193m; and Based on the downhole geophysical and camera survey, WB12 is screened entirely within the UEVF. Despite casing issues, this bore will be retained for observational purposes only.	Bore to be retained as an observation bore only
WB13	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, and was therefore decommissioned. The bore was perforated at a depth of 160 m.	Decommissioned
WB14	Obstruction removed and bottom of bore confirmed at 214 m. Geophysics data confirmed that this bore is screened within the UEVF. The bore was found to be in good working order.	Retained
WB15	Obstruction removed and bottom of bore confirmed at 225 m. Geophysics data confirmed that this bore is screened within the UEVF. The bore was found to be in good working order.	Retained
WB16	WB16 is the pumping bore. Prior to undertaking the pumping test in May 2021, the bore was inspected by downhole geophysics and CCTV camera. The bore was found to be in good working order.	Retained
WB17	Obstruction pushed down to 177 m. The geophysics data confirmed that this bore was cross-screening the UEVF and MEVF; therefore, the bore was perforated at a depth of 167 m and was decommissioned.	Decommissioned

2.3 Previous Studies and Historical Evidence Defining Groundwater Extraction Risks

As with most major projects, there has been active community interest in the proposed activity with some attention based on the perception that historical groundwater extraction has led to an adverse impact on the lower Anglesea River estuary.

The main concern from some community members is that the Estuary water quality has become more frequently acidic from 2016 onwards, with the primary cause of this acidity being the more frequent drying out of the water table in the shallow alluvial creek systems (where the acidity is stored).

One community group hypothesises that historical groundwater extraction has primarily led to a large reduction in surface water flow for Salt Creek between 2010 to 2023 when compared to 1968 to 1982 flow. This has in turn lead to more frequent drying of the alluvial waterways which builds acidity, with this acidity released when the sediments are rewetted following a wet period.

Alcoa understands that the community members position is primarily formulated on the following observations:

1. Dewatering of a thin coal seam under the shallow waterways has increased its permeability, facilitating leakage from shallow aquifers to underlying aquifers.
2. Groundwater extraction has caused a “cone of depression” under the shallow alluvial systems (as shown by the declining groundwater pressure in SOB 116459); and to compensate, surface water must be leaking from above.

The above hypotheses and more have been tested throughout this GIA with the proposed activity informed by a number of investigations, with many significant scopes of work subject to independent peer review process. With respect to the above, this section summarises historical lines of evidence and their uncertainties as well as studies which led to an increased understanding of how and if groundwater extraction may impact surface water behaviours; refer **Table 2-3**.

Table 2-3 Key References or Lines of Evidence Used to Understand Catchment and Groundwater Behaviours to Stresses

Report or Line of Evidence	Evidence or Description of Catchment and Groundwater Behaviours to Stresses
Groundwater levels and quality Example Reports include: Groundwater Monitoring Reports (Coffey, 2006 to 2022) Anglesea Borefield Project Isotopic and Tracer Studies (GHD, 2011a) Quarterly Mine Water Body Monitoring 2020 to 2024)	Groundwater level and quality data has been collected across the catchment with some groundwater levels dating back to 1969. This includes: • Barwon Water groundwater level monitoring data at 32 observations points throughout the catchment. • The State Observation Bore Network (SOBN). Within the catchment there exists 12 active observation bores, with the primary purpose of the SOBN being to collect groundwater data for observational purposes. This data is used for research and other informative measures, and to improve the access and management of groundwater. • Alcoa Groundwater Bore Network. Alcoa have 80 active groundwater bores located across the former power station or the mine lease. Details and objectives of these bores are further discussed in Section 4. The location of the above bores is shown on **Figure 2-9**. For analysis of the above, key lines of evidence regarding surface water and groundwater behaviour are described in the following bullet points. Please refer to **Appendix A**, CHM report, that provides figures illustrating the relevant lines of evidence. • The "cone of depression" is observed in the lower section of the UEVF. The geological layers between mined main coal seam and the lower sands remain fully saturated, with some geological layering under the mine having hydraulic pressures higher than the shallow Alluvial water tables. • Groundwater mounding underlying or adjacent the ASA near the former PowerStation and UEVF pumping bores following significant rainfall or flow events is not observed from daily monitoring groundwater, indicating in this area these leakage rates from the ASA to underlying aquifers is not a significant migration pathway. • The direction of groundwater flow in the shallow aquifers is towards the mine void indicating the mine void and not UEVF groundwater extraction is influencing shallow water tables in the vicinity of the mine. • The direction of groundwater flow in the upper part of the UEVF is towards the historical sump pump location. • Continuous pressure monitoring data from Vibrating Wire Piezometers (VWPs) from above the main coal seam (in the Demons Bluff Group) from 1999 to 2011 as well as those installed around the former power station from 2006 show no response to drawdown from pumping in the lower sands of the UEVF; further, over the course of the UEVF pumping test in May 2021, no bore screened in aquifers above the UEVF lower sands showed any response to the pumping test. • Groundwater levels in the Alluvial Swamp Aquifer (ASA) responds closely to seasonal rainfall, declining when the proceeding months are low in rainfall and/or evapotranspiration is likely high. • Groundwater trends in the ASA behaves similarly regardless if the UEVF potentiometric surface or "cone of depression" is higher or lower than the watertable in the ASA. • In some areas, groundwater salinity in aquifers underlying and adjacent to the ASA are significantly higher, whilst in others it is significantly fresher than the median TDS at Salt Creek stream flow gauge SV2 (refer **Section 5.8** for a summary of catchment hydrology). • Surface water pH at or within the vicinity of Anglesea River (Marshy Creek) stream flow gauge AV2 has been consistently less than pH 4.0 since monitoring began in 1970; conversely, groundwater pH within the UEVF ranges 5.5 to 7.5 (mean 6.5).

Report or Line of Evidence	Evidence or Description of Catchment and Groundwater Behaviours to Stresses
	• Isotope analysis of residual water pools in the ASA indicated that these pools were not supported by groundwater; rather, these pools were located in areas of low potential evapotranspiration, GHD (2013).
Geology Controls Example References include: Barton, C. M. (1995). Hancock, (1967) Holdgate, et al., (2001) Mining One (2012 and 2017).	The following information summarises the geological lines of evidence that has been presented in past reports which suggests significant geological controls exist to govern surface water and groundwater interactions: • The Bells Beach anticline forces the UEVF to become quite shallow (<50 metres below ground level (m bgl) 7km north of the mine (under the mid reaches of Marshy Creek), whereas the Anglesea syncline forces the UEVF to become quite deep (>300m bgl) to the south and west of the mine (under Salt Creek). • When the first production bores were completed in the 1960's, the supervising hydrogeologist reported minor sands lenses were encountered between layers of clay and coal, with each sand lens recoding a rise in groundwater pressure as a result of "lithostatic pressure"; e.g., groundwater within these lenses are highly confined. • At a location just to the north of the former PowerStation, exploration undertaking in the late 1960's found slight artesian conditions were observed when drilling hit a sand lens at a depth of 138 mbgl. This is the top of the UEVF lower stands. Sand lenses above this were not artesian. • The installation of 8 UEVF observation bores surrounding the mine to depths of up to 150m as well as geophysical logging of Alcoa's existing deep production and observation bore network revealed the UEVF contains many aquifers (sand lenses) throughout its 250m sequence under the mine void. The deepest sand sequences were the target of Alcoa's UEVF extraction. • Above the lower sand lenses, a total cumulative thickness of over 100m of fully saturated low permeability clay and coal sequences separate the pumped section of the UEVF and the mine void. Laboratory permeability tests of these clay and coal sections indicate that permeability ranges from 3 x 10^{-9}m/sec to 7 x 10^{-10} m/sec. This is equivalent of the permeability of an engineered landfill liner. • A review of 22 exploration geological bore logs located either within or adjacent to the ASA (the peaty sediments confined within Salt Creek and Marshy Creek) have an average thickness of 27.7m (max = 86m; min = 2.4m) of either clay or silt (e.g., low permeability material) that separates the base of the ASA to the next most permeable layer underlying the surface water systems. • A review of all bore logs reveal the upper sands of the UEVF form a discontinuous permeable unit and are primarily found underneath the basal clay in the vicinity of the former mine and potentially extend towards the coast. These sands are likely recharged by rainfall where these sands are located near the surface. • There is a clay unit (referred to as the basal clay) underlying the mined coal seam which inhibits vertical groundwater movement. At the deepest part of the mine void, during the course of the coal mining, this underlying clay was likely extracted. A "sump pump" was historically installed in this location to keep the mine void dry; as a result, this sump pump was not only removing local catchment runoff and shallow groundwater ingress, but also dewatering the thin upper sand layers of the UEVF.
Climate	The following information suggests climatic conditions are the most important contributor to overall catchment surface water flow: • Using over 120 years of catchment specific data (e.g., climate data from a gridded point adjacent the mine from the SILO database [https://www.longpaddock.qld.gov.au/silo/]) it is clear the region has seen significant shifts in climate. Between the two periods of 14-year

Report or Line of Evidence	Evidence or Description of Catchment and Groundwater Behaviours to Stresses
	available surface water flow that are available for comparison (i.e., 1968 to 1981 and 2010 to 2023) there is vastly different rainfall statistics: o Total rainfall between 1968 to 1982 was 9,994 mm with an average of 714mm/yr. o Total rainfall between 2010 to 2023 was 8,515mm with an average of 608mm/yr. o The above means that during 2010 to 2023, the catchment received 1479mm less rainfall when compared to 1968 to 1982. Using a high level catchment yield calculator (refer Water Calculator (agriculture.vic.gov.au) this drop in rainfall represents a decline in more than 12,000[2] ML of surface water. • Four out of the top five driest five-year totals on record for the region have occurred since 1990, with the only other significant dry periods being the Federation drought at the start of last century as well as the severe drought between 1914 - 1918. • Zhang et al. (2016) investigated 222 high-quality stream gauging stations having 30 years or more continuous unregulated streamflow records from the Bureau of Meteorology's Hydrologic Reference Stations (HRS) dataset. The results found most of the stations in southeastern Australia spread across New South Wales and Victoria showed a significant decreasing trend in annual streamflow post 1997. • Using the HRS to analyse data closer to Anglesea in several gauges located away from waterways with upstream control structures, it is observed that significant declines in streamflow have also been observed since 1997 in nearby catchments. These observations are summarised below: o Stream flow at Werribee River at Ballan has seen a 65% decline since 1997 when compared to 1974 to 1996 (incl). This reduction increased to a 94% decline using data from cumulative dryer years (2006 to 2009). o Stream flow at Woady Yaloak River at Pittfield has seen a 77% decline since 1997 and this increased to a 94% decline using data from cumulative dryer years (2006 to 2009; 22% drier than 1900 to 1997). o Stream flow at Lerderderg River at U/S Goodman Ck Junction has seen a 65% decline since 1997 and this increased to a 95% decline using data from cumulative dryer years (2006 to 2009; 22% drier than 1900 to 1997). o Stream flow at Creswick Creek at Clunes has seen a 70% decline since 1997 and this increased to a 98% decline using data from cumulative dryer years (2006 to 2009; 22% drier than 1900 to 1997).

[2] Catchment Area = 11670 Ha; Catchment yield co-efficient of 7

2.4 Community Engagement

2.4.1 Introduction

Consultation and engagement with stakeholders are a priority in the development and approval process for the mine's rehabilitation and closure, the decommissioning and remediation of the power station site, and future land use planning.

The water filling strategy for the mine has been a key topic in Alcoa's community engagement activities and forums for many years.

Since 2015, Alcoa has been conducting broad engagement activities about the future of the Alcoa site to ensure community and key stakeholder feedback is well considered in Alcoa's decision making. Key activities have included the Alcoa Community Consultation Network (CCN) which was established in 2001, regular email updates to the large community database (950+ people), advertorials (Alcoa Community Update) in the Surf Coast Times newspaper, ongoing participation in the Anglesea River Advisory Committee, and updates provided via the online Anglesea Community Network bulletin (run by the community) to regularly cover the mine water filling strategy.

Since 2020 in particular and including the 2021 Groundwater Pumping Test, engagement has focussed on the potential use of groundwater from the Upper Eastern View Formation (UEVF) to help expedite the filling process.

To provide further information and opportunities for community feedback about the potential use of groundwater from the UEVF, Alcoa has produced a range of materials since this time, distributed widely via Alcoa's large community database and the various media described above.

Between May 2021 and September 2022, Alcoa provided monthly Groundwater Pumping Test Reports as updates to the community including key technical information, groundwater trends, and status of monitoring bore triggers and any associated investigations. These reports concluded 10 months after the actual pumping test itself was completed.

During the development of the updated Conceptual Hydro-geological Model for the Alcoa area of interest during 2022/2023 and the updated Anglesea Groundwater Numerical Model during 2023/2024, Alcoa continued to provide updates to the community using regular email updates to the large community database (950+ people), advertorials (Alcoa Community Update) in the Surf Coast Times, ongoing participation in the Anglesea River Advisory Committee, and updates provided via the online Anglesea Community Network bulletin.

During this period, Alcoa also made significant efforts to engage directly with the recently formed Friends of the Anglesea River community group who have expressed concerns related to the impact of Alcoa's historical groundwater extraction on Salt Creek surface water flows. This has included numerous face-to-face meetings and responding to many and varied questions during this time.

With the completion of the update to the Anglesea Groundwater Numerical Model early in 2024 allowing the progression of the final anticipated groundwater impact and risk assessment technical works, Alcoa undertook further engagement in the form of Open House events conducted from 23-25 May 2024, allowing for even greater community engagement on the topic of the water filling strategy.

The purpose of these three open house sessions in Anglesea, was to provide an opportunity for local community members to learn about the company's potential plans to fill the mine void with groundwater from the UEVF aquifer and hear the latest on rehabilitation of the former mine and power station sites.

- Thursday 23 May from 4:00pm to 6:00pm – 24 attendees.
- Friday 24 May from 10:00am to 12:00pm – 16 attendees.
- Saturday 25 May from 10:00am to 12:00pm – 62 attendees.

Alcoa provided detailed information boards related to various aspects of the water filling strategy to structure the information for the community, a copy of these boards is provided in the community engagement report referred to below.

The sessions were part of a comprehensive community engagement initiative, which leveraged a number of communication channels to generate community awareness and attendance. In total, 102 members of the local community dropped in to the sessions, seizing the opportunity to discuss the technical findings with Alcoa representatives and Alcoa's technical experts, demonstrating strong community interest.

The outcomes of this engagement are summarised below, with the Community Engagement Report made available to the community also attached as **Appendix H**.

In addition to the above, Alcoa has provided regular briefings to representatives of the local Traditional Owners – the Wadawurrung People. This has included technical briefings to their team related to surface and groundwater, site tours as 'walks on country' focussed on the mine rehabilitation and more specially the water related features of the area. The most recent briefing was provided during June 2024 providing a detailed overview of the groundwater investigations and outcome of these over approximately the last four years and Alcoa's intent to apply to SRW for an amended license. No objections or significant concerns were raised as part of this, or since with the information shared directly with the Traditional Owner team for further consideration.

2.4.2 Community Open House Engagement Objectives

The open house community engagement strategy encompassed two main objectives.

1. To provide the opportunity for local community members to learn about the potential plans to fill the mine void with groundwater from the UEVF aquifer and provide opportunities for feedback prior to any future application to Southern Rural Water.
2. To provide an update on the latest on rehabilitation of the former mine and power station sites including the opportunity to engage directly with Alcoa representatives and their technical experts.

2.4.3 Target Audience

A broad range of community and key stakeholders including Anglesea residents and homeowners, businesses, members of local community and interest groups and the general public.

2.4.4 Communication, Advertising, and Materials

While the subject of the mine void water filling strategy is well known to the Anglesea community having been covered on an ongoing basis since 2020 as described above, a multi-channel approach was adopted to inform the community and stakeholders about the open house sessions. Copies of the advertising collateral are provided in the attached Community Engagement Report.

Methods to advertise the open house sessions and the extent of each are shown in **Figure 2-12** and included:

- Direct email via Alcoa database to 979 direct community email addresses;
- Use of the Alcoa website www.alcoa.com.au/anglesea including featured FAQ's;
- Event listings via the Surf Coast Shire website event calendar;
- Advertorial and editorials in the Surf Coast Times and the Armstrong Creek Times newspapers;
- Multiple direct outreaches to community interest groups (including the Friends of the Anglesea River);
- Multiple direct outreaches to other key stakeholders including local and state government representatives, authorities, regulators, and ongoing engagement with the Wadawurrung local Traditional Owner representatives; and
- Use of a Facebook and Instagram campaign.

Figure 2-12 Summary of how the Sessions were Advertised

2.4.5 Summary of Open House Community Engagement Results

A total of 102 community members dropped in to one of three, 2-hour sessions hosted at the Anglesea Bowling Club, with many spending a significant period of time reading the information boards displayed around the room and conversing with Alcoa representatives and their technical experts.

Alcoa engaged independent communications agency, Keep Left, to capture community feedback throughout the sessions via a simple questionnaire - comprising three questions.

Prior to leaving the sessions, community members were invited to provide feedback, by completing the questionnaire themselves, or verbally while one of the two Keep Left representatives recorded the response. The questionnaire comprised three questions, and of the 102 attendees, more than half (65) chose to provide feedback.

The following data analysis aims to summarise the feedback provided, including categorisation of common themes and sentiment. A copy of all the completed feedback forms is provided within the attached Community Engagement Report.

Q1 Has this session helped you to better understand the Anglesea Mine Rehabilitation and Closure Plan?

- The vast majority (88 per cent) of attendees responded yes.
- Some respondents (9 per cent) didn't provide a clear response or made an alternative option, such as maybe - for the purpose of this analysis, these have been categorised as other.
- Only two attendees (3 per cent) responded no.

Q2 Has this session informed you about what viable options there are to fill the mine pit?

- The vast majority (86 per cent) of attendees responded yes.
- Seven respondents (11 per cent) responded no.
- While two were categorised as other.

Graphical presentation of results for Question 1 and 2 is shown in **Figure 2-13**.

Q3 Is there any additional information you'd like to learn about the potential strategy to fill the mine pit, or in regards to the Anglesea Mine Rehabilitation and Closure Plan?

- The nature of this question prompted respondents to say what additional information they would like regarding the mine water filling strategy and broader Anglesea Mine Rehabilitation and Closure Plan, whilst also providing opportunity for general comments or feedback.
- While some respondents directly answered this question by specifying the exact information that they would like, many others used the free text field as an opportunity to provide their views and opinions about the project.
- The majority of feedback was unsurprisingly related to the water filling strategy given this was the main topic of the open house sessions, however a number of other topics were raised as shown **Figure 2-14** .

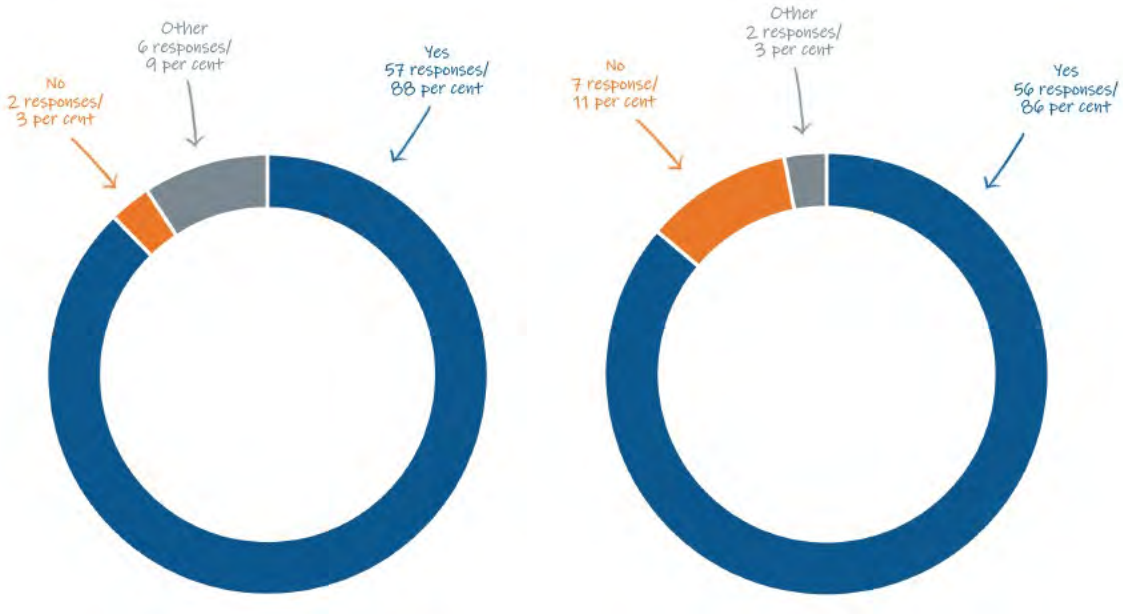

Figure 2-13 Question 1 Summary (left); Question 2 Summary (right)

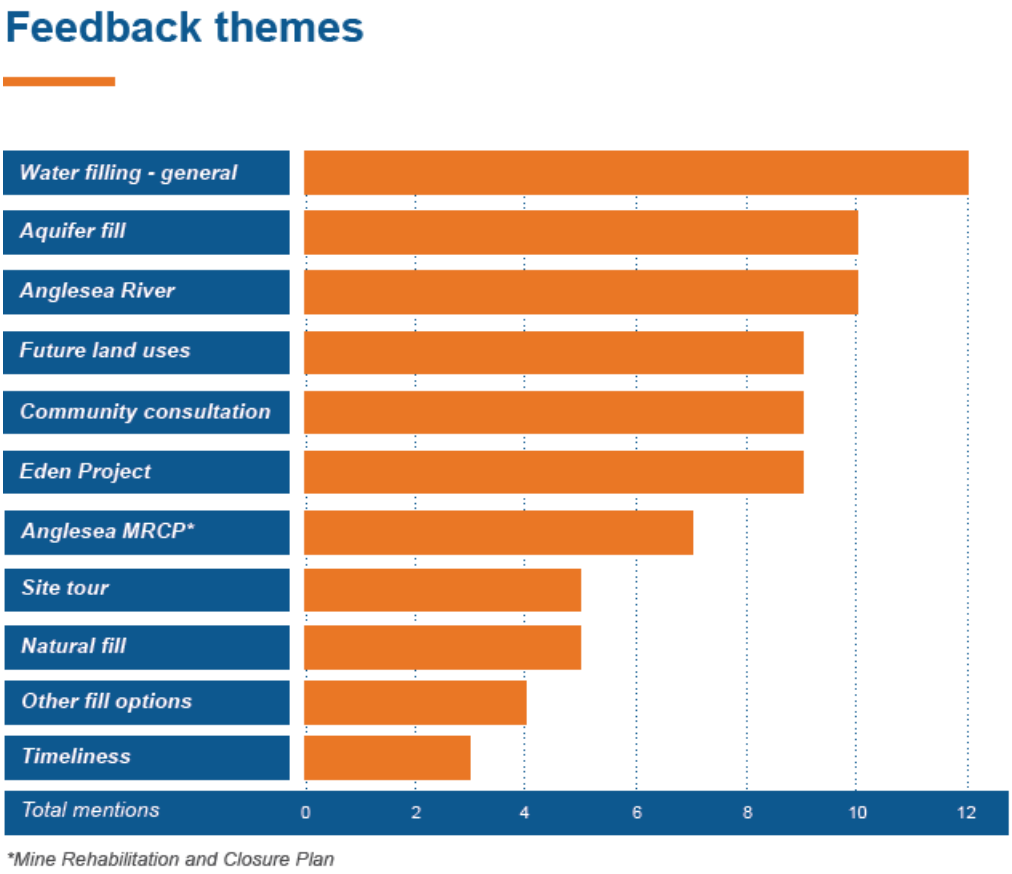

Figure 2-14 Question 3 – Feedback Themes

An analysis was also undertaken of the feedback provided in an attempt to determine the general community sentiment towards the proposed water filling strategy. This indicated that the majority of feedback (56 per cent) was assessed as being neutral in tone, just under a third (32 per cent) of respondent feedback was assessed as being positive in nature, and feedback from nine respondents (14 per cent) was assessed as being negative in nature.

2.4.6 Conclusion from Open House Community Engagement

Throughout the sessions, Alcoa representatives and technical experts engaged in numerous constructive conversations with individuals who showed genuine interest in the work being undertaken.

Many were equally as appreciative of the opportunity to be informed, with positive comments highlighting the sessions' informative nature, the professionalism of the presentation, and the accessibility of the representatives. This notion also aligns with the majority sentiment gleaned from the feedback forms and from the data analysed.

A summary of all the feedback collected during the open house sessions is detailed below:

- 88 per cent of feedback received indicated that attendees felt they better understood the draft Anglesea Mine Rehabilitation and Closure Plan.
- 86 per cent of the feedback received indicated that attendees felt informed about what viable options there are to fill the mine pit.
- The majority of feedback (56 per cent) was assessed as being either neutral in tone or positive (32 per cent), with only 14 per cent assessed as negative.

2.4.7 Ongoing Community Engagement Activities

Alcoa is committed to keeping the community informed about the proposed water filling strategy, including most recently (July 8, 2024) providing a copy of the Community Engagement Report to the Alcoa email database (950+), posting this on the Alcoa Anglesea website, and also sharing this directly via the online Anglesea Community Network.

Using these established engagement tools Alcoa will continue to seek feedback from interested community members and key stakeholders.

Alcoa will also continue to use these tools to continue to provide updates to the community about the status of the proposed groundwater license amendment once it is made to Southern Rural Water.

Ongoing feedback

Ongoing feedback and questions are always invited and responded to by Alcoa in all communication materials via emails to angleseaps@alcoa.com.

3 Relevant Regulatory Framework

3.1 Commonwealth Legislation

3.1.1 Environment Protection and Biodiversity Conservation Act 1999 ('EPBC Act')

The EPBC Act provides a legal framework to protect and manage nationally and internationally important flora, fauna, ecological communities, and heritage places – which are defined in the EPBC Act as Matters of National Environmental Significance (MNES). The EPBC Act has the following objectives:

- Provide for the protection of the environment, especially matters of national environmental significance;
- Conserve Australian biodiversity;
- Provide a streamlined national environmental assessment and approvals process;
- Enhance the protection and management of important natural and cultural places;
- Control the international movement of plants and animals (wildlife), wildlife specimens, and products made or derived from wildlife;
- Promote ecologically sustainable development through the conservation and ecologically sustainable use of natural resources;
- Recognise the role of Indigenous people in the conservation and ecologically sustainable use of Australia's biodiversity; and
- Promote the use of Indigenous peoples' knowledge of biodiversity with the involvement of, and in cooperation with, the owners of the knowledge.

The Australian Department of Sustainability and Environment, People and Communities (DSEWPAC, 2013) provides for protection of environmental matters on Commonwealth land.

Where a project or activity may negatively impact an MNES the activity should be referred to the Australian Government Minister for the Environment.

An EPBC Act self-assessment is a report prepared by project proponents which identifies MNES within the project area and the likelihood of the project impacting the MNES. If a self-assessment concludes that MNES will not be impacted, a referral to the Minister and formal assessment under the EPBC Act is not required.

As indicated by this groundwater impact assessment for the proposed extraction, risks of adverse impact to groundwater dependent eco-systems including the Anglesea River are low, and as such the likelihood of impacting any MNES is also low. On this basis it has been concluded by Alcoa that a referral to the Minister and formal assessment under the EPBC Act is not required.

3.2 State Legislation

3.2.1 Water Act 1989

In the context of groundwater, the Water Act principally deals with the sustainable, efficient, and equitable management and allocation of the resource. It also provides a means for the protection and enhancement of all elements of the terrestrial phase of the water cycle. Approvals are required under the Water Act for:

- Construction of bores for monitoring, dewatering, or aquifer recharge; and
- Extraction of groundwater, or aquifer reinjection/recharge.

The State assessment process will consider:

- The impact of the extraction on water availability within the area;
- Public and agency submissions;
- Water quality impacts;
- Existing water allocations;
- Natural processes and aquifers; and
- A requirement for approval of the licence will be to demonstrate no significant impact on the Section 79 Rehabilitation plan.

3.2.2 Mineral Resources (Sustainable Development) Act 1990

Mineral exploration, extraction, and the rehabilitation of mine sites is regulated by the Mineral Resources (Sustainable Development) Act 1990. This Act is overseen by Resources Victoria and the ERR unit, a part of the Department of Energy, Environment and Climate Action (DEECA)

A draft MRCP was developed in 2017 in compliance with Section 79 Rehabilitation plan. Key rehabilitation plan elements[3] include:

- The proposed post mining land use.
- Defined rehabilitation areas.
- Rehabilitation objectives.
- Rehabilitation criteria.
- Schedule for rehabilitation milestones.
- Rehabilitated land risk assessment.

3.2.3 Environmental Protection Act 2017

A key part of the Environment Protection Amendment Act is the general environmental duty (GED). This approach focuses on preventing waste and pollution impacts rather than managing those impacts after they have occurred. This duty requires people to undertake reasonably practicably steps to eliminate, or otherwise reduce risks of, harm to human health and the environment from pollution and waste. A breach of GED could lead to criminal or civil penalties. This concept is analogous to Victoria's existing Occupational Health and Safety laws.

[3] Microsoft Word - Preparation of rehabilitation plans - Guidelines for mining and prospecting projects February 2020.docx (earthresources.vic.gov.au)

3.2.4 Climate Change Act 2017

The Climate Change Act provides Victoria with a legislative foundation to manage climate change risks, maximise the opportunities from decisive action, and drive a transition to a climate resilient community and economy with net zero emissions by 2050.

3.2.5 Environment Effects Act 1978

The Environment Effects Act provides for assessment of proposed projects (works) that are capable of having a significant effect on the environment. The responsible Minister decides whether an Environment Effects Statement (EES) should be prepared. The EES process involves:

- Referral to the Minister for Planning;
- The Minister's decision on the need for an EES;
- Preparation of scoping requirements for the EES studies and reporting;
- Preparation of the EES report;
- Public review (exhibition and lodgement of submissions);
- Ministerial assessment of environmental effects; and
- Consideration of the assessment.

3.2.6 Catchment and Land Protection Act 1994

The Catchment and Land Protection Act 1994 establishes a series of reginal catchment strategies throughout Victoria. The Anglesea mine is located in the Corangamite catchment area. The Corangamite Regional Catchment Strategy outlines the catchment authorities vision for water, biodiversity, land, coast & marine, and communities within the catchment area. Under the Water Theme in the Corangamite Regional Catchment Strategy are four Sub-themes waterways, wetlands, estuaries, and groundwater.

Potential impacts on waterways, groundwater, or wetlands should have reference to the catchment strategy, and:

- Our Living Rivers of the Barwon, A Discussion Paper for the Future.
- Corangamite Natural Resource Plan for Climate Change.
- Corangamite Regional Floodplain Management Strategy, 2018-2028.
- Corangamite Waterway Strategy, 2014- 2022.
- Guidelines for assessing the impact of climate change on water availability in Victoria – 2020.
- Long Term Water Resource Assessment.
- Port Phillip Bay (Western Shoreline) and Bellarine Peninsula Ramsar Site Management Plan.
- Victorian Index of Stream Condition 2010.
- Western District Lakes Interim Ramsar Site Management Plan.

3.3 State and Local Planning Schemes

The State Planning Policy Framework (SPPF) is common to all Victorian planning schemes, and contains policies in relation to various policies, guidelines and standards. The SPPF has specific provisions relating to the environment, specifically the protection of catchments, waterways and groundwater. In terms of strategies within specific clauses:

- Clause 12.03-1S River corridors, waterways, lakes, and wetlands. To protect and enhance river corridors, waterways, lakes, and wetlands.

- Clause 13.01 – 1S Natural hazards and climate change. To minimise the impacts of natural hazards and adapt to the impacts of climate change through risk-based planning
- Clause 13.04-3S Salinity. To minimise the impact of salinity and rising watertables on land uses, buildings and infrastructure in rural and urban areas and areas of environmental significance and reduce salt load in rivers.
- Clause 14.02 – 1S Catchment planning and management. To assist the protection and restoration of catchments, water bodies, groundwater, and the marine environment.
- Clause 14.02-2S Water quality. To protect water quality
- Clause 19.03-3S Integrated water management. To sustainably manage water supply, water resources, wastewater, drainage and stormwater through an integrated water management approach.

The above clauses apply across the State, but each local council within the project area may have additional clauses in its local planning scheme relating to groundwater and sustainable environmental practices.

3.4 Policies, Guidelines, and Standards

3.4.1 National Guidelines and Policies

3.4.1.1 Groundwater Modelling Guidelines 2012

The objective of the guidelines is to promote a consistent and sound approach to the development of groundwater flow and solute transport models in Australia. Numerical groundwater modelling undertaken to assess impacts to groundwater has adopted these guidelines.

Note: These guidelines contain outdated approaches when it comes to aspects like model calibration as well as model classification. The traditional approach of developing a single calibrated model can give a false expectation that there is a single deterministic set of best parameters. Best practice now calls for derivatives of suites of plausible parameters that reflects the uncertain nature of the history-matching “calibration” process, which can be extended to predictive uncertainty analysis in an efficient manner. This probabilistic approach has become more widely applied in groundwater modelling since the publication of the guidelines in 2012.

3.4.1.2 Minimum Construction Requirements for Water Bores in Australia 2020 (Edition 4)

The guidelines outline the minimum requirements for constructing, maintaining, rehabilitating, and decommissioning water bores in Australia. They are used extensively by regulators and the drilling industry and provides a consistent standard reference across Australia for the licensing of bores and drillers. Investigations undertaken to characterise the groundwater environment of the project have adopted these guidelines.

3.4.1.3 NHMRC, NRMMC 2011 Australian Drinking Water Guidelines Paper 6 National Water Quality Management Strategy

The guidelines are intended to provide a framework for good management of drinking water supplies that, if implemented, will assure safety at point of use. The ADWG have been developed after consideration of the best available scientific evidence. These guidelines have been applied to assess groundwater quality.

3.4.1.4 ANZG 2018 Australian and New Zealand Guidelines for fresh and marine water quality.

The guidelines outline the management framework recommended for applying the water quality guidelines to the natural and seminatural marine and freshwater resources in Australia and New Zealand. The guidelines provide a summary of the water quality objectives proposed to protect and manage the environmental values supported by the water resources, and advice on designing and implementing water quality monitoring and assessment programs.

3.4.1.5 NHMRC 2008 Guidelines for Managing Risks in Recreational Waters

The primary aim of these guidelines is to protect the health of humans from threats posed by the recreational use of coastal, estuarine and fresh waters. Threats may include natural hazards such as surf, rip currents and aquatic organisms, and those with an artificial aspect, such as discharges of wastewater. These guidelines have been applied to assess groundwater quality.

3.4.2 State Guidelines and Policies

3.4.2.1 Environment Reference Standard

The Environment Reference Standard (ERS) is part of the Environment Protection Act 2017 and commenced on 1 July 2021. The ERS identifies environmental values that the Victorian community want to achieve and maintain and provides a way to assess those environmental values in locations across Victoria.

The ERS is itself made up of many reference standards. These reference standards are in groups that cover four aspects of Victoria's environment:

- Ambient air;
- Ambient sound;
- Land; and
- Water (surface water and groundwater).

Each reference standard identifies an environmental value. Most reference standards also have indicators and objectives. These are how we assess if the environmental value is being achieved, maintained or threatened. An indicator is something we measure. An objective is the level of an indicator, or a way of using an indicator, to help us assess the environmental value.

3.4.2.2 Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems 2015

These guidelines are a supplement to a section of the Water Act 1989 where a groundwater Take and Use Licence application is made. It requires applications to undergo a risk assessment and referral process.

3.4.2.3 Aboriginal Water Program

The Aboriginal Water Program is a partnership between the DEECA and Traditional Owners and Aboriginal Victorians to manage our waterways and catchments across the State. Importantly, it is reconnecting communities to water for cultural, economic, customary and spiritual purposes.

3.4.3 Responsible Authority

Rural Water Corporations are responsible for issuing groundwater licences for any water other than mains supply (which is managed by urban water authorities). At Anglesea, Southern Rural Water is the Responsible Authority.

3.4.3.1 Groundwater Licensing

A licence to take and use groundwater may be issued by the Minister under Section 51 of the Water Act 1989. Approvals under the Water Act, such as for bore construction, groundwater extraction (dewatering) or artificial groundwater recharge may also be required by the project from the relevant water corporation, Southern Rural Water.

3.4.3.2 Discharge to Surface Water

Discharge of groundwater to surface systems would need to be assessed based on the EPA Victoria Publication 1287 (EPA Victoria, 2009), via a risk-based approach.

There are quality differences between the Upper Eastern View Formation (UEVF) groundwater and the existing surface water within the mine void. These are summarised in the **Table 3-1** and **Table 3-2.** Overall pH is lower in the water body and sulfate, calcium, aluminium and boron are more elevated compared to the UEVF groundwater. However, due to the elevated concentration of iron and reducing conditions of the UEVF groundwater, the pH of the UEVF groundwater is anticipated to be similar once the iron oxidises when discharged to the water body.

Table 3-1 Water Composition – Major Ions

Sample Location	Date	pH	Sodium mg/L	Potassi-m mg/L	Calcium mg/L	Magnesium mg/L	Chloride mg/L	Sulfate (as SO4) mg/L	Alkalinity (as CaCO3) mg/L
Water Body	9/11/22	3.6	250	19	87	82	427	626	<1
UEVF (WB12)	8/11/22	6.8	150	17	29	49	384	64	72

Table 3-2 Water Composition – Minor Ions

Sample Location	Date	Aluminium mg/L	Barium mg/L	Boron mg/L	Iron mg/L	Manganese mg/L	Zinc mg/L
Water Body	9/11/22	5.33	0.0509	1.23	2.59	0.555	0.582
UEVF (WB12)	8/11/22	0.0002	0.11	0.227	13.9	0.56	0.0116

Geochemical modelling has been used to simulate the addition of UEVF groundwater into the existing water body to achieve the final water elevation of 5.5 mAHD. The outcome of the modelling, refer to **Section 8.1.4** for more information, indicates no change in pH, minor increases in chloride and manganese and minor increases in other constituents of interest as provided in Table 3-3.

Therefore, the activity of discharging UEVF groundwater is not considered to be 'pollution' and neither is the existing water body considered to be 'polluted' as it is representative of the surrounding background catchment water quality.

Table 3-3 Comparison of one, four, and ten Year Fill Scenarios

Fill Scenario	pH	Sodium	Potassium	Calcium	Magnesium	Chloride	Sulfate	Aluminium	Barium	Boron	Iron	Manganese	Zinc
	S.U.	*mg/L*											
Initial	3.60	250	19	87	82	373	627	5.34	0.05	1.23	2.59	0.56	0.58
Final 1yr	3.49	182	18	43	59	420	200	1.06	0.03	0.44	0[4]	0.60	0.14
Final 4yr	3.50	196	17	48	63	410	267	1.09	0.02	0.44	0	0.61	0.20
Final 10yr	3.54	241	16	61	77	413	441	1.23	0.01	0.48	0	0.70	0.34

[4] PHREEQC model precipitates iron (as iron mineral species) if oversaturated, in reality the mine water is supersaturated with iron

3.5 Summary

With reference to EPA Victoria Publication 1287 (EPA Victoria, 2009), specifically discharge of groundwater to surface systems, geochemical modelling indicates no change in pH, minor increases in chloride and manganese and minor increases in other constituents of interest, however the activity of discharging UEVF groundwater is not considered to be 'pollution' and neither is the existing water body considered to be 'polluted' as it is representative of (and still will be) the surrounding background catchment water quality

With reference to the EPBC Act and the requirement for a self-assessment referral, as part of the options assessed included within the draft MRCP and inclusive of the progressive rehabilitation works over the past nine years, and this GIA determining risks of adverse impact to GDE's including the Anglesea River are low, it was concluded that a self-assessment was not required due to the low risks (or ability to progressively manage) of any proposed works.

In compliance with Section 79 of the Sustainable Development Act 1990, a draft MRCP was developed and submitted to ERR in 2017. Within this Plan, it was presented that water is required to accelerate the filling of the mine void to achieve the MRCP objectives.

As such and in accordance with Section 51 of the Water Act 1989 which deals with sustainable, efficient, and equitable management and allocation of water resources, Alcoa are seeking to obtain approval from Southern Rural Water (the Responsible Authority) to reduce their existing Groundwater Licence (BEE029662), from 4000 ML/yr to 1,500 ML/yr and amend its use to allow this groundwater to accelerate filling of the former Anglesea coal mine to achieve the MRCP objectives.

To ensure the reduced and amended allocation poses no unacceptable risks to the environment that may rely on groundwater, an impact assessment (**this report and its supporting appendices**) has been developed in accordance with EPA Victoria Publication 688.1 Hydrogeological assessment guidelines for groundwater quality and Section 59A of the Water Act (1989).

This assessment also aligns with the precautionary principal and satisfies Section 40 of the Water Act 1989 as the results presented in this application err on the side of conservatism as the numerical results which form the risk assessment have isolated Alcoa's pumping impact from other cumulative impact contributors such as Barwon Waters Bulk Entitlement and climatic factors, also presented in this application. By using this approach, the modelled outputs are more conservative (i.e. Alcoa's modelled impact is likely greater than may be realistically observed, thus satisfying Section 40 of the Water Act 1989). This is further discussed in **Section 0**.

4 Datasets

This chapter sets out the list of all historical surface water data, groundwater data and climate data used to support this GIA, and broader work assessments completed to support the development of the MRCP. Where specific datasets are derived for a particular purpose, e.g., mine pit geochemical mixing, this data is presented in the relevant chapter.

Where appropriate this report also provides a compilation of all data and assesses this against the defined data quality objectives (DQOs). By undertaking this, potential data limitations or data uncertainties can be documented. Where limitations or uncertainties exist, the water management, monitoring, and contingency plan (refer **Section 10**) presents the approach for where, when, and how additional data and/or supplemental assessments or mitigation measures will be adopted.

4.1 Data Quality Objectives

In addition to the numerical groundwater model Quantities of Interest (refer **Section 7.2**), EHS Support developed the following DQOs with reference to relevant guidelines published (for example Australian and New Zealand Environment and Conservation Counsel, National Environment Protection Council, Australian Government Department of Agriculture and Water Resources, and Victorian requirements), which define minimum data requirements and quality control procedures.

The DQO process is used to establish performance or acceptance criteria and serves as the basis for designing a plan for collecting data of sufficient quality and quantity to support the goals of a study. The DQO process consists of seven iterative steps that are documented in **Figure 4-1**. While the interaction of these steps is portrayed in **Figure 4-1** in a sequential fashion, the iterative nature of the DQO process allows one or more of these steps to be revisited as more information on the problem is obtained.

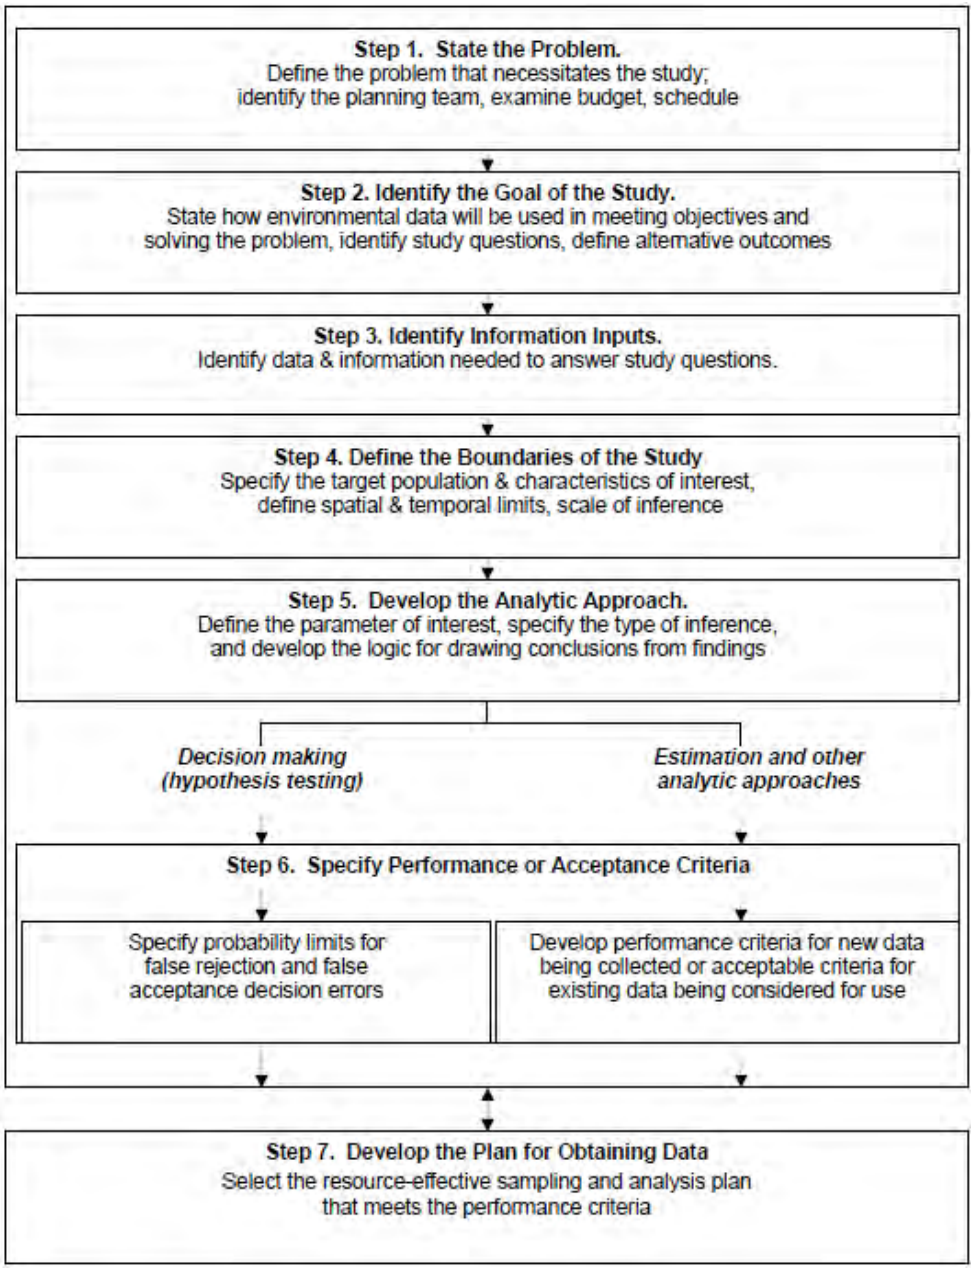

Figure 4-1 Data Quality Objective Process

Each step of the DQO process defines criteria that will be used to establish the final data collection design. The first five steps are primarily focused on identifying qualitative criteria, such as:

- The nature of the problem that has initiated the study and a conceptual model of the environmental hazard to be investigated;
- The decisions or estimates that need to be made and the order of priority for resolving them;
- The type of data needed; and
- An analytic approach or decision rule that defines the logic for how the data will be used to draw conclusions from the study findings.

A summary of the site wide DQOs is provided in **Table 4-1**.

Table 4-1 Summary of DQOs

DQO Step	DQO Overview
Step 1 – State the Problem	The Alcoa Anglesea Power Station and Coal Mine was permanently shut down on 31 August 2015. Alcoa is required to develop a MRCP and implement actions that establish a safe, stable, and sustainable landform. The MRCP comprises a final mine void waterbody surrounded by safe and stable batters and revegetated areas. The MRCP also depicts the preferred option to return a final mine void waterbody, this is now proposed to be achieved via groundwater pumping from the lower sands of the UEVF. The intent is to ensure that pumping of the UEVF does not result in potential unacceptable risk to the environment, such as impacts to GDEs, generation of acidic conditions, impacts to surface water quality and flows etc, a GIA is required.
Step 2 – Identify the Goal and Decisions	The goal of the GIA is to assess potential risks to the environment due to pumping of the UEVF aquifer to fill the mine void. Environmental data has been collected as part of the GIA to assess the following key decisions: • Will pumping of the EUVF result in impacts to GDE. o What aquifers support GDE at the site and in the surrounding area (i.e., ASA and DBG); o Is the UEVF hydraulically connected to GDE, or the aquifers which support them (i.e., ASA and DBG); o Will pumping of the UEVF result in a significant reduction in groundwater levels in the ASA and DBG; and • Will this reduction result in adverse impact to the GDE. • Will pumping of the UEVF result in a significant reduction in groundwater levels of the ASA and DBG resulting in the potential oxidation of Potentially acid sulphate soils (PASS) and generation and mobilisation of acidic conditions within the Anglesea River or its tributaries (and in turn impact ecological health and the broader environment). • Will pumping of the UEVF result in a reduction in surface water flows at Anglesea River and Salt Creek, and if so, will this reduction in flow impact ecological health either directly or indirectly (i.e. through acid generation). • Will the filling of the mine void with groundwater pumped from the UEVF compromise the water quality of surrounding shallow aquifers such as ASA and DBG, and in turn, impact on ecological health. • Are there any groundwater users of the UEVF (i.e., extractive uses such as drinking water, irrigation, stock watering, etc.) in the surrounding area, and if so, will these groundwater users be impacted by pumping of the UEVF.

DQO Step	DQO Overview
Step 3 – Identify Inputs to the Decision	Several previous and historical assessments and investigations have been completed at the site in order to assess potential impacts to the environment due to groundwater pumping of the UEVF. Data from these investigations provide inputs to make the above decisions, and includes (but not limited to): • Surface water data (flow pathways, historical and current flows, water quality, groundwater-surface water interactions, background water quality). • Mine void water data (water levels, evaporation rates, water quality, groundwater-surface water interactions, predicted future water quality). • Groundwater data (historical and current groundwater levels, continuous groundwater level monitoring, groundwater quality data [including quality data from various aquifers including UEVF, ASA and DBG], groundwater seasonal and temporal fluctuations, groundwater-surface water interactions, background groundwater quality). • Climatic data (historical and current rainfall, humidity, pressure, evaporation. etc.). • Publicly available data (i.e., surrounding groundwater users, SOBN historical data, general historical information, etc.). The inputs will be used to inform a hydrogeological risk assessment and help to make the defined decisions.
Step 4 – Define the Study Boundaries	The mine site boundary is shown on **Figure 2-1**; however, for the purpose of this GIA the site boundary also includes the Anglesea River and Salt Creek catchments and the extent of the LEVF, UEVF, ASA, and DBG aquifers which may be impacted by groundwater pumping based on measured and modelled drawdown. The GIA also assumes groundwater pumping will be conducted over a period of 10 years.
Step 5 – Develop a Analytical Approach (or Decision Rule)	The following decision rules have been established: • Groundwater data indicates that pumping of the UEVF does not result in a significant reduction in groundwater levels in shallow aquifers of the ASA or DBG, and in turn, is unlikely to impact on GDE (or vice versa). • Groundwater data indicates that pumping of the UEVF does not result in a significant reduction in groundwater levels in shallow aquifers of the ASA or DBG, and in turn, is unlikely to result in oxidation of PASS and generation and mobilisation of acidic conditions (or vice versa). • Groundwater data indicates that pumping of the UEVF does not result in a reduction in surface water flows, and in turn, is unlikely to impact ecological health either directly or indirectly (or vice versa). • Groundwater and surface water data indicates that the water quality of the UEVF once in the mine void is unlikely to impact surrounding shallow aquifers such as the ASA and DBG, and in turn, is unlikely to result in impacts to ecological health (or vice versa). • There are no groundwater extractive users in the surrounding area likely to be impacted by pumping of the UEVF (or vice versa).

DQO Step	DQO Overview
Step 6 - Specify Performance or Acceptance Criteria (Limits on Decision Errors)	Decision errors that may occur due to uncertainties or limitations include concluding that there is no impact when there in fact is. To prevent this, the following performance criteria will be adopted: • Adopting industry standard and best practice approaches to assess potential impacts. • Undertaking works in accordance with relevant National, State, and local legislation, regulations, standards, and guidelines, including, but not limited to: o ANZECC/ARMCANZ (2000). National Water Quality Management Strategy. Australian and New Zealand Guidelines for Fresh and Marine Water Quality, 2000; o ANZG 2018. Australian and New Zealand Guidelines for Fresh and Marine Water Quality. Australian and New Zealand Governments and Australian state and territory governments, Canberra ACT, Australia. o Australian Government Department of Agriculture and Water Resources (2018). National Acid Sulfate Soils Guidance – Guidance for the dewatering of acid sulfate soils in shallow groundwater environments, 2018; o DELWP (2016). Guidelines for Assessing the Impact of Climate Change on Water Supplies in Victoria, 2016; o Environment Protection Act 2017 o NEPC (2013). National Environment Protection (Assessment of Site Contamination) Measure, 2013. o Victoria Government (2021) Environment Reference Standard. Victoria Government Gazette No S245, 26 May 2021. Melbourne. Victoria. Australia • Establishing a detailed understanding of background aquifer and surface water conditions based on historical groundwater, surface water and climate data. • Implementing a Water Management Monitoring and Contingency Plan (WMMCP) (refer to **Section 10**) to ensure ongoing surveillance of potential impacts to the environment during pumping of the UEVF and filling of the mine void. • Implementation of robust QA/QC procedures and acceptance limits; and • Adopting the null hypnosis that potential impacts exist unless proven otherwise.
Step 7 – Optimise the Design for Obtaining Data	The GIA is based on historical and more recent assessments. A WMMCP (refer to **Section 10**) has also been proposed and has been optimized based on the information provided by the various supporting datasets and assessment.

4.2 Datasets

4.2.1 Surface Water

The main surface drainage features in the Anglesea area are described below and shown on **Figure 4-2**.

- Salt Creek and its associated swamps and tributaries (such as Breakfast Creek);
- Upper Anglesea River/Marshy Creek and its associated swamps and tributaries; and
- Lower Anglesea River.

With reference to the proposed activity, the overarching data objectives are as follows:

1. Obtain surface water flow data used for model history-matching (previously referred to as "calibration") and uncertainty analysis approaches applied with the numerical groundwater flow model;
2. Prediction of mine void water body quality; and
3. An assessment of groundwater/surface water interaction.

Over the last 20 years, the catchment hydrology has been extensively studied for a range of reasons. These have primarily focused on the catchment acid generating potential, as both the Anglesea River and Salt Creek and its tributaries experience frequent low pH water quality (pH 2-4) or acid flows due to naturally occurring conditions.

Key datasets were reviewed to gain an understanding of the background surface water conditions. A summary of the historical water quality results from Upper Anglesea River/Marshy Creek (AV2) and Salt Creek (SV2) are presented in **Table 4-2** and **Table 4-3**, respectively.

4.2.2 Mine Water

With reference to the proposed activity, the overarching data objective is to assess background water quality to enable:

- Predicting the potential impacts of mine void water quality; and
- Bench-marking performance criteria.

The key data that were reviewed to gain an understanding of the background mine water conditions are presented in **Table 4-4**; note, prior to March 2016, analysis of the mine void water has most likely been from the mine reclamation pond and as such not included in **Table 4-4**. As demonstrated on **Figure 4-3**, this is not a direct sample of the pit water (sump) as the reclamation pond resides after the pit water is directly pumped out and into a small wetland prior to entering the reclamation pond. This wetland residence time is unknown and therefore this data must be treated with caution.

Post 2016 EHS Support has undertaken detailed water quality analysis of the mine void water (at the sump), however this period has been affected by authorised ash management activities (as seen in the large increase in pH) in the mine void and may not entirely be representative of background conditions. This is the data presented in **Table 4-4**.

4.2.3 Groundwater

As noted in **Section 2.2.4.1**, Alcoa have implemented a groundwater monitoring network that includes 87 observation bores (**Figure 2-9**). With reference to the proposed activity, the overarching data objectives are:

- Obtain reliable groundwater level data used for model history-matching (previously referred to as "calibration") and uncertainty analysis approaches applied with the Anglesea groundwater numerical model;
- Assess background groundwater quality to understand the potential for groundwater mixing; and
- Understand surface water/groundwater interactions.

A comprehensive database of groundwater levels and groundwater quality exists. This information is summarised in the CHM report included as **Appendix A** and a summary of sentinel bores is presented in **Table 4-5**. Hydrographs of "**bolded**" bores are presented in **Appendix D.**

4.2.4 Climate

With reference to the proposed activity and information presented in **Section 5**, the overarching data objectives were to assess climatic conditions (specifically rainfall and evaporation) across the site to:

- Obtain input parameters for numerical groundwater modelling;
- Understand water body evaporation rates; and
- Understand evapotranspiration.

Six meteorological weather stations exist across the site, with the closest weather stations to the site being Wensleydale 6km to the northwest and Aireys Inlet 6km to the southwest. The weather stations and the data considered in this study are presented in **Table 4-6** with all meteorological data derived from www.bom.gov.au.

Table 4-6 Key Meteorological Weather Stations

BOM Station Name	Station ID	From	To	Lat	Long	Temp	Rainfall	Evap
Aireys Inlet	90180	1994	Current	-38.458	144.0883	x	x	
Wensleydale (Anglesea (Vehicle Proving Ground)	87119	1965	Current	-38.368	144.0843		x	
Torquay Golf Club	87160	1974	2016	-38.340	144.3101		x	

BOM Station Name	Station ID	From	To	Lat	Long	Temp	Rainfall	Evap
Wurdiboluc Reservoir	87126	1969	2016	-38.282	144.0518		x	x
Buckley (Balliwindi)	87124	1968	Current	-38.250	144.0854		x	
Boonah	90187	2001	Current	-38.411	143.9771		x	

In addition to the above, catchment specific data has been obtained from the SILO database (https://www.longpaddock.qld.gov.au/silo/). SILO is a database of Australian climate data from 1889 and are constructed from observational records provided by the Bureau of Meteorology. SILO interpolates the raw data, using nearby BOM climate stations to derive datasets which are both spatially and temporally complete (more information can be found at (https://www.longpaddock.qld.gov.au/silo/about/overview/).

As observed in **Table 4-6**, continuous climate data does not exist at any one station spanning 1900 to current. The Australian climate change site networks (http://www.bom.gov.au/climate/change/hqsites/) doesn't have a station close to the mine; therefore a dataset was obtained from SILO (Point Patched Dataset (PPD) for the location shown on **Figure 4-5**. This location was chosen as it was close to the mine and equi-distance from coastal and higher relied stations and thus representative of the surface water catchments that feed Anglesea. **Figure 4-4** presents the side-by-side comparison of annual rainfall from Aireys Inlet, Wensleydale and the SILO (Point Patched Dataset (PPD) location shown on **Figure 4-5**.

5 General Environment

5.1 Topography and Land use

The topography of the Anglesea area is presented in **Figure 5-1**. The land surface falls rapidly from 300 m AHD to 400 m AHD in the west to 0 m AHD along the coastal plains.

The topographically elevated areas to the west of Anglesea are dominated by forest. This primarily comprises native vegetation conservation areas, with smaller areas of production and plantation forestry (**Figure 5-1**). Across the flatter areas to the north and east, grazing pastures dominate. Urban land use is limited to small areas at the coastal towns. Several large and small marsh and wetland areas are found across the region. There are extensive swamp areas immediately northwest of Anglesea along the Anglesea River and Salt Creek (**Figure 5-1**).

5.2 Climate

The Anglesea area is characterised by relatively high rainfall in the topographically elevated areas to the west, with decreasing rainfall across the lower northern and eastern areas. The two closest rainfall gauges are located at Wensleydale (BOM ID 87119), approximately 6 km northwest of the mine (within Anglesea River Catchment), and Aireys Inlet (BOM ID 090180), approximately 6 km southwest of the mine along the coast.

Long-term average annual (LTA) rainfall at Wensleydale is 769 millimetres per year (mm/yr) based on data from 1935 to current. At Aireys Inlet, the LTA is 616 mm/yr based on data from 1994 to current. Yearly averages are presented on **Figure 5-2** along with rainfall surplus/deficit data from Wensleydale.

Since measurements began in 1965 at Wensleydale, rainfall data indicates a distinct wetting and drying phase. Using SILO, a longer-term record can also be derived beginning 1900, and this identifies a 3rd climatic phase (**Figure 5-3**). This climate signature shows:

- Between 1900 and 1950, the region exhibited a neutral to drying climate.
- Between 1950 and 1990, the region then experienced a strong wet period.
- Since 1990, a prolonged drying period is observed. The millennial drought (late 1996 to mid-2010) occurs in this period.
- Since 1990, 4 out of the top 5 driest 5-year totals on record for the region have occurred (**Figure 5-4**). The only other significant dry period being the drought during 1914-1918. This is an important consideration as recent surface water flows in Salt Creek (at monitoring point SV2) have been significantly lower than those recorded from 1969 to 1982; (refer to **Section 5.8** for more information on surface water flow data).

Seasonally rainfall is variable, with around 60 percent of total annual rainfall falling over the months of May through October. Heavier episodic rainfall (greater than 50 mm/day) generally occurs in Spring and Summer with almost 70 percent of these falls occurring in this period.

Mean annual potential evaporation (PE) does not vary significantly across the region, with an annual mean of 1,300 mm measured at Anglesea. Further information on evaporation (including lake evaporation) is discussed in **Section 5.2.1**.

5.2.1 Evaporation on Water Bodies

Typically, evaporation from surface water bodies (such as a lake), are calculated using Morton's Lake Coefficient or a Synthetic Class A Pan Coefficient. However, Morton's Lake Coefficient is for a shallow lake, and Synthetic Class A Pan Coefficient is for a shallow evaporation-pan. Therefore, to determine evaporation from a deeper lake (i.e., the mine void water body), both need to be converted by a coefficient to relate them to evaporation for a deep lake (greater than 1.0 m depth).

The standard conversion-factor for Pan to lake is generally 0.75 x Potential Evaporation (PE). For the mine void, PE was calculated using FAO56[5] and SILO Data Drill system6 for the site. The results indicated the ratio between the Synthetic Class A Pan Coefficient and FAO56 is 0.725; therefore, the unadjusted FAO56 is close to lake evaporation and its direct use without adjustment can therefore be used as the simplest estimate of lake evaporation.

McJannet et al. (2017, 2019) undertook a study whereby evaporation from a mine void lake using analytical, actual and modelling approaches were compared. The results found that aerodynamic modelling provided the closest match to actual floating pan evaporation, whilst applying the standard Class A pan measurements sometimes provided poor correlation, especially where shading from steep side walls and high evaporation rates are common (such as in northwestern Australia). As the former Anglesea mine, neither has steep sided walls or experiences very large seasonal fluctuations in temperature using the approach above is considered representative and no direct evaporation measurement is necessary.

Figure 5-3 shows a plot of PE (FAO56) and rainfall from SILO, as well as actual annual rainfall deficit for a site at the mine void (Lat. and Long. of -38.40^{o} 144.15^{o}, decimal degrees). This rainfall deficit was then used across the surface area of a full mine void (approximately 100 Ha at +5.5 m AHD) to determine likely actual evaporative losses as opposed to PE. On average, evaporative losses (rainfall deficit) per year were estimated at 311 mm/year or about 0.31 GL/yr of water at full storage (100 Ha x $1x10^{4}$ x 311mm/year x $1x10^{-9}$).

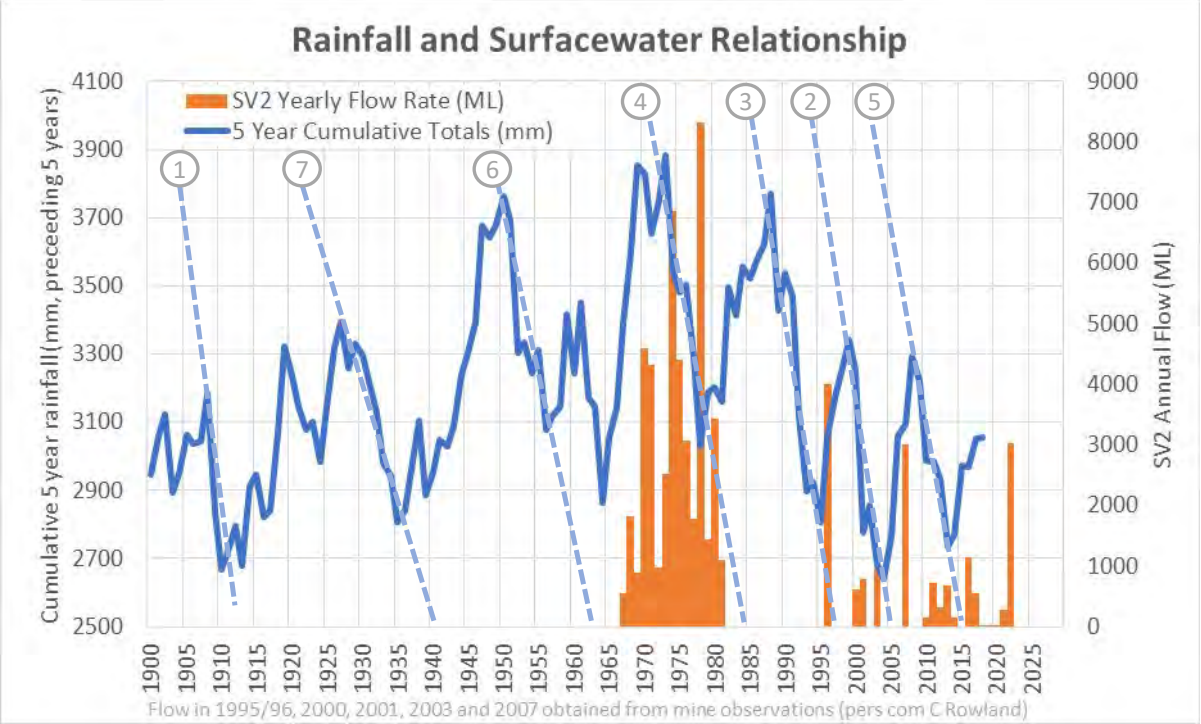

Figure 5-4 Rainfall and Surface water Relationship

5.3 Climate Change

As shown in **Figure 5-3** and discussed in **Section 5.2**, there is evidence of three strong climatic cycles over the last 120 years. Between 1900 and 1950, the region exhibited a drying climate, defined by average annual rainfall typically being lower than the LTA rainfall. Between 1950 and 1990, the region then experienced a strong wet period where above average rainfall fell for 27 out of 40 years. Recently, however, the rainfall surplus/deficit has again begun to fall with drier than average conditions dominating over the last 30 years. An important observation from **Figure 5-3** is the rate of decline (slope of the rainfall surplus/deficit) observed over the last 20 years is occurring 1.5 times faster than observed during the drying phase of 1900 to 1950.

As a result of this historical climate variability, the Victorian Government prepared a series of guidelines (Department of Environment, Land, Water and Planning [DELWP], 2016) outlining how the climate change projections can be applied for water resource planning in Victoria. These guidelines are based on 42 global climate models (GCM) and applied to generate climate change projections for Victoria's river basins for the years 2040 and 2065. With respect to this report, the Otway Coast basin is the relevant river basin.

A summary of the climate change projections for the Otway Coast basin are presented below for two projections: low (10th percentile) and high (90th percentile) impact on water availability from climate dependent sources. The results suggest:

- Average daily temperature is projected to increase by 1.0 °C by 2040 and 1.9 °C by 2065 relative to the current climate baseline.
- Potential evapotranspiration is projected to increase by 3.7 percent by the Year 2040, and 6.4 percent by 2065 relative to the current climate baseline.

- Average annual rainfall is projected to range from a decrease of 11.7 percent (high scenario) to an increase of 2.1 percent (low scenario) by the Year 2040, with a 3.6 percent decrease in rainfall for the medium climate change scenario. By 2065, rainfall is expected to range from 19 percent reduction (high scenario) to a 0.5 percent increase (low scenario). The median climate change scenario predicts a 5.8 percent relative reduction to the current climate baseline.
- Average annual runoff is projected to range from -25.3 percent to -6.6 (median = -15.8 percent) by the Year 2040. By 2065, annual runoff is projected to range from -41.9 percent to -4.7 percent (median = - 7.2 percent) relative to the current climate baseline.

With respect to sea level rise, future rises are projected for key areas in Victoria based on the 2015 national sea level projections (CSIRO and BoM, 2015). By the 2030s, sea level is projected to rise by around 12 cm (range of 7–18 cm) (relative to 1986–2005) under medium (RCP4.5) and high (RCP8.5) emissions scenarios. By the 2070s, the emissions scenario has greater impact, with increases of around 32 cm (range of 20–46 cm) under RCP 4.5, but up to 42 cm (range of 26–54 cm) under RCP 8.5.

In addition, the Victorian Governments Future Coasts Program7 is preparing policy of planning for not less than 0.8 m of sea level rise by 2100. Note: if this level of rise did occur it would only impact the estuary. The lowest point of Coal Mine Road which runs between the top of the estuary and the former mixing zone has an elevation of 5.0 mAHD.

5.4 Soils

Regionally, to the north and west of Anglesea, the soils are dominated by sandy uniform units formed on the Tertiary-aged sediments of the EVF. Further to the east, the dominant soil type changes to the more clay rich soils formed on the more recent Neogene-aged marls and non-calcareous sediments of the Jan Juc Formation and the DBG. In the topographically elevated and forested areas in the west, the soils are dominated by texture contrast soils formed on the Lower Cretaceous-aged sedimentary rocks of the Otway Group.

Locally, soils generally exhibit acid duplex profiles from three distinct profile types developed from differing parent materials. The three main characteristics of the vast majority of soils across the site are the distinct texture contrast between the light-textured sandy surface soil and the clay subsoil:

1. Sandy podzols and podsolic soils: These tend to be developed on older Tertiary sediments and therefore tend to be more prevalent on the lower sections of slopes. These highly leached acidic soils are characterised by sandy topsoils and low fertility with deficiencies in phosphorus, potassium, nitrogen, copper, zinc and molybdenum (Pitt, 1977).
2. Lateritic podsolic soils: These are generally developed on the plateau remnants of the Tertiary peneplain. The A horizons of these soils have a loamy texture with an organic aluminium (A1) and bleached A2 horizon, changing sharply to well-structured silty clay at a depth of approximately 40 cm. Ironstone blocks and nodules are ubiquitous at around a depth of 1 metre.
3. Acid peaty soils: These are developed in local creek beds and may be up to several metres in depth. Although nutrient levels are high, they are not freely available to plants due to a pH less than 4 (Kentish and Bourne, 1983).

5.5 Catchment Acidity and Acid Sulphate Soils

Acidity in the Anglesea River catchment is a topic that has been researched extensively over the last 20 years and all studies to date acknowledge the catchments naturally high pyrite and sulphur content as the main source of acidity or acid drainage.

In the most recent study, Wong et al., (2020), investigated the distribution and characterisation of acid sulfate soils in the Salt Creek and Marshy Creek Swamplands. The study involved field sampling of 28 sites within the course of the Anglesea Swamplands and a further 25 sites along the marshlands associated with Salt Creek.

The study identified three modes of acidity at each site:

i) Potential sulfidic acidity, sourced from sulfidic sediments containing pyrite and monosulfides;
ii) Labile acidity, which is existing acidity and can be rapidly mobilised; and
iii) Retained acidity, which is existing latent acidity usually stored in minerals such as jarosite. In addition, acid neutralising capacity was also analysed, and net acidity determined.

The report found that both Salt Creek and Marshy Creek contain substantial volumes of acidity in a form that can be mobilised rapidly. Marshy Creek contains higher concentrations of labile acidity which can be transported readily in surface water and groundwater, whereas Salt Creek contains higher concentrations of retained acidity which can be slowly released over time.

Given it is known that the catchment is naturally acidic, the hydrogeological system contributes to acid generation and transport in 3 ways:

- Fluctuating watertables - falling watertables introduce air into moist pore spaces of the unsaturated zone.
- Dissolved oxygen can be transported to pyrite by groundwater recharge.
- Groundwater flow, specifically in the vadose zone, transports any acid generated.

These factors are schematically shown in **Figure 5-5**.

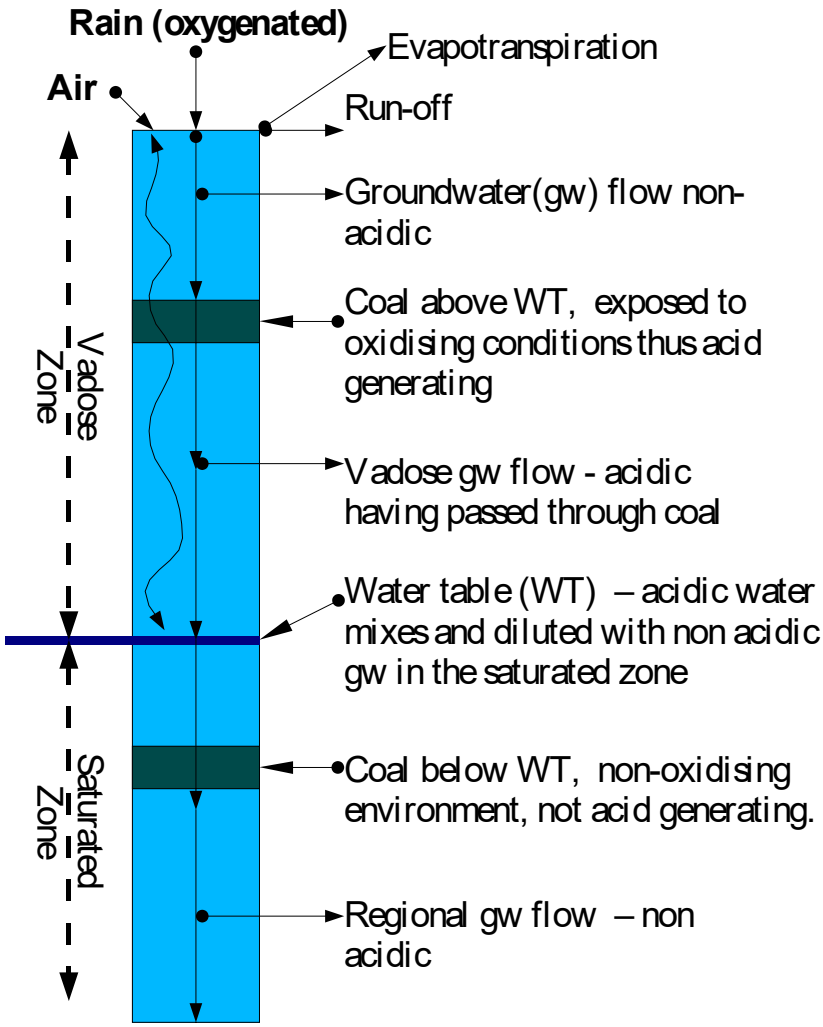

Figure 5-5 Model of Acid Generation and Transportation from Sulphide Containing Units of the Anglesea Geological Sequence (after Tutt 2008)

The key processes of the cycle which directly influence acid generation and transport in the Anglesea catchment are precipitation, infiltration, percolation and groundwater to lakes and streams (refer **Figure 5-6**).

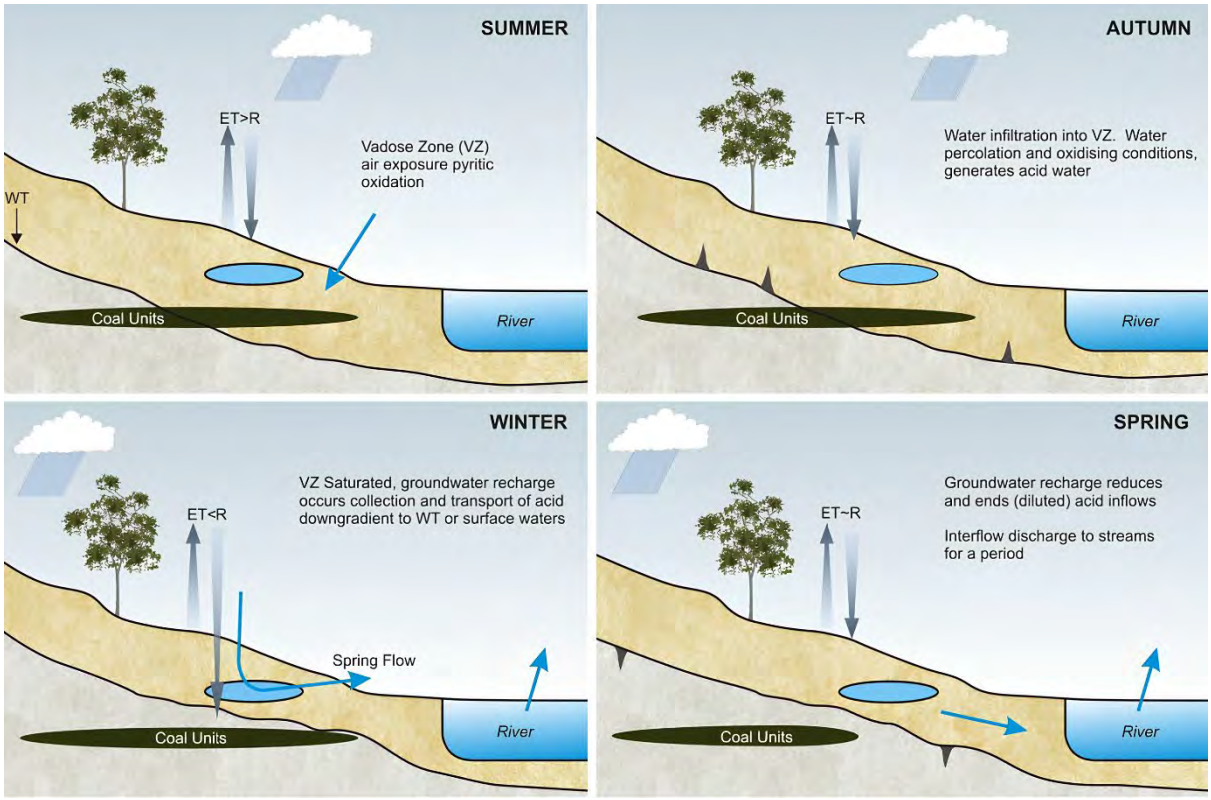

Figure 5-6 Modified Conceptual Model of Seasonal Acid Generation and Transportation Mechanisms (after Tutt 2008, reference GHD 2013)

As depicted in **Figure 5-6**, some acid generation and transportation should theoretically occur every year. Over winter and spring, water infiltrates and percolates into the vadose zone oxidising pyrite and transporting acidic water downgradient. This water can either discharge as a spring flow to the surface or mix with the existing groundwater within the shallow alluvial aquifer.

Seasonal rainfall therefore directly influences the rate of acid generation and transportation. Variation to normal weather patterns, including extended dry periods, which may drop the water table and affect acid generation and transportation, potentially creating scenarios such as:

- Low recharge to the shallow groundwater system causing reduced generation and transportation of acid in the systems and a potential build-up of acid in pore spaces.
- High recharge to the shallow groundwater system causing greater oxidation of pyrite plus increased transportation as percolating groundwater flushes pore water from the vadose zone.

In addition to Wong et al., (2020), other detailed studies that summarise the sources of acidity in the catchment are summarised in the CHM report in **Appendix A**.

5.6 Groundwater Users

The location of the groundwater users (such as private and commercial water bores) is shown on **Figure 5-7**. Groundwater bores within the local area have been determined through a search of the Victorian Water Measurement Information System (WMIS). The WMIS database was undertaken in 2024 to identify registered bores within a 10 km buffer of the mine void and within the Jan Juc GMA.

Figure 5-7 shows a high density of stock, domestic and irrigation bores located to the northeast of the Jan Juc GMA (north of Torquay); however, these bores are generally shallow and intersect the groundwater resources of the Beaumaris Sandstone (formerly known as the Moorabool Viaduct Sands) or the shallow sediments of the DBG. Of these bores, only two appear to be completed in the UEVF. Bore ID 68160 is completed to a depth of 278.9 m and located ~3 km southeast of the mine near the coast. Bore ID 68179 is completed to a depth of 28 m in coal and is approximately 8.5 km northeast of the mine. This bore sits within the Jan Juc syncline and due to the Bells Beach Anticline separating the UEVF at the mine and this bore, they are not connected.

Beginning 2007, Barwon Water installed seven production bores (GW1 to GW7) in the LEVF (refer **Section 2.2.3**).

Lastly, the Moriac Quarry has a licence to extract 250 ML/year. The quarry is located approximately 13 km north of the mine void with groundwater extracted from the LEVF (up-gradient of the site) and used for industrial sand washing purposes.

5.7 Potential Environmental Sensitive Receptors and Groundwater Dependant Ecosystems

Across the catchment there have been many studies that have assessed the nature and extent of GDEs that may occur within the catchment along with the aquatic ecology of the surface water systems. Many of these are summarised in **Figure 5-8** with the section below providing the most current understanding. Specifically, the following Environmental Sensitive Receptors (ESRs) and potential GDEs are discussed: summarised in GHD (2013) and the CHM report in **Appendix A**.

- Anglesea River and Salt Creek Permanent Pools.
- Anglesea River and Salt Creek Vegetated Marshlands.
- Anglesea River Estuary.

Additional information on the terrestrial and aquatic ecology of the catchment can be found by Ecology Australia (2007–2013) and GHD (2012–2016).

5.7.1 Anglesea River and Salt Creek Permanent Pools

As part of Barwon Waters Anglesea Borefield Project, a number of persistent pools in upper catchments of both water courses have been identified and include (**Figure 5-8**):

- Upper Anglesea Persistent pools (named AGP1-B, AGP2 and ASP7); and
- Salt Creek Persistent pools (SGP1-A and SGP2-B).

These pools (or potential GDEs) were identified as key asset points in the outcrop area associated with the LEVF, which had the potential to be significantly impacted by dewatering activities, as:

- They appeared to be permanent pools and therefore considered baseflow dependent.
- They are located in the interpreted LEVF outcrop area and hence likely to be in direct connection with the aquifer being pumped, also situated at the LEVF outcrop area closest to the Barwon Water borefield, and therefore impacts were possible in the short term.
- Southern Pygmy Perch was identified in the Salt Creek pools suggesting the pools may have a relatively high ecological value as habitats for these fish.

However, GHD (2011a) undertook a detailed investigation on these pools. These studies used stable oxygen isotopes, chlorofluorocarbons and radiocarbon to better understand surface water and groundwater interactions. The results, as well as yearly surface water quality monitoring from 2012 to 2019 confirmed that these pools, with the exception of SGP1-A, are not in direct connection with the underlying aquifer and not baseflow dependant, rather they are perched systems recharged by surface water flows.

5.7.2 Anglesea River and Salt Creek Vegetated Marshlands

Groundwater dependent ecosystems as defined by the Ministerial guidelines for groundwater licensing and the protection of high value groundwater dependent ecosystems (DELWP, 2015) means those ecosystems that require access to groundwater to meet all or some of their water requirements so as to maintain the communities of plants and animals and ecological processes they support and the ecosystem services they provide. This definition has also been used in the recent Anglesea River and Estuary Environmental Flow Study (GHD, 2021).

Whilst there is always conjecture in determining the degree of groundwater reliance of certain GDEs (a process that often takes years and a high level of detailed studies to define), GHD (2021) presents that there are some vegetated communities in the swamplands within the Anglesea River and Salt Creek Catchment (defined in this report as the vegetation on top of the Alluvial Swamp Aquifer (ASA)) that rely on less than 10 percent groundwater contribution and therefore meet the definition of a GDE. These swamplands are typically found in the mid and upper reaches of Salt Creek and Marshy Creek and are shown on **Figure 5-8**

Importantly, no other GDEs or areas where they could exist were identified, and to date no other GDEs have been identified where they are in direct connection to the UEVF.

5.7.3 Anglesea River Estuary

The Anglesea River Estuary is an important environmental and community asset in the region. Multiple lines of evidence suggest that the estuary is hydraulically disconnected from the main aquifers within the UEVF and LEVF and include:

- Monitoring of shallow aquifers (DBG/ASA) in the vicinity of the former power station show no changes in water level despite climatic events and aquifer stresses.
- The top of the UEVF under the estuary occurs at a depth of 115 mbgl (refer bore log for P14, GHD, 2010).
- Underneath Marshy Creek adjacent to the former power station, ~30 m of coal, clay and silty clays separate the base of the Creek to the top the UEVF.
- Pre-development (Hancock, 1967) noted small artesian conditions near the former power station from a bore screened 138 mbgl. This indicates that the presence of clay layers between the surface and the water bearing zones are strongly confining.

5.8 Catchment Hydrology

The main surface drainage features in the Anglesea area are:

- Upper Anglesea River/Marshy Creek and associated swamps and tributaries.
- Lower Anglesea River (Estuary).
- Salt Creek and its associated swamps and tributaries (e.g., Breakfast Creek).

Figure 4-2 and **Figure 5-8** shows the location of surface water features and monitoring points discussed throughout this section.

5.8.1 Anglesea River

The total catchment extent is approximately 65 km^2. Swampy heath and heathy woodlands predominate in the catchment. The Anglesea River is described in three segments:

- Upper reaches of the Anglesea River (i.e., Marshy Creek).
- Swamps associated with the mid-reaches of Anglesea River/Marshy Creek.
- Lower Anglesea River.

Geographically, the Lower Anglesea River is defined to begin downstream of monitoring point SP6 at Coal Mine Road. The swamps are located between monitoring point SP6 and 1 km upstream of monitoring point AV3. The upper reaches are located above this point.

Table 5-1 discusses the Anglesea River inter-gauge flow differences and flow statistics are described in **Section 5.8.1.1**. Furthermore, it is noted that stream flow characteristics observed at the end of the catchment are considerably different between the 2 periods of 14-year available surface water flow data that are available for comparison i.e. 1968 to 1981 and 2010 to 2023. The difference (reduction) in observed flow and potential causes is discussed in **Section 5.8.3.**

5.8.1.1 Upper Anglesea River/Marshy Creek

The upper reaches of the Anglesea River/Marshy Creek are ephemeral; however, GHD (2013) reports that several non-groundwater fed, permanent pools exist across its reach (monitoring points AGP1-A, AGP1-B and AV1, **Figure 5-8**). These reaches drain the eastern flanks of the Otway Range, and much of the outcropping LEVF and MEVF from the west to the east near Gum Flats Road.

The ephemeral nature of flow within the Anglesea River catchment is evident in stream gauging data. Upstream monitoring point AV1 shows around 250 days per year (nearly 70 percent of the year) with no recordable flow. **Figure 5-9** shows flows since 2009 and **Figure 5-10** shows flows from 2019 to 2021.

5.8.1.2 Swamps

The swamp associated with Anglesea River/Marshy Creek is primarily located between AV3 and SP6 near the former power station. Within this stretch, surface water flow is ephemeral and usually dry during the summer; however, it has a number of wetlands that may be present year-round (GHD, 2013). During large first flush events of these swamps (i.e., first flows after a prolonged period of no flow), significant volumes of low pH water can be flushed into the estuary (Lower Anglesea River), which cause metals precipitation and, in some cases, fish kills. Historical data shows that the estuary exhibits low pH (<5) in two out of every three years.

At monitoring point AV2, which is located just upstream of the former power station, data indicates that there are on average 134 days per year (37 percent of the year) that show no recordable flow for the period 2009 to 2021. Note, AV2 was installed in 2009, much later than gauging station SV2 on Salt Creek.

For periods where baseflow is sustained for longer periods than average, **Figure 5-10** presents typical flow duration curves using runoff events from 2019 to 2021 from AV2 (lower catchment) and AV1 (upper catchment). This shows discharge in AV2 runs for a longer period of time than in the upper catchment (**Table 5-1**).

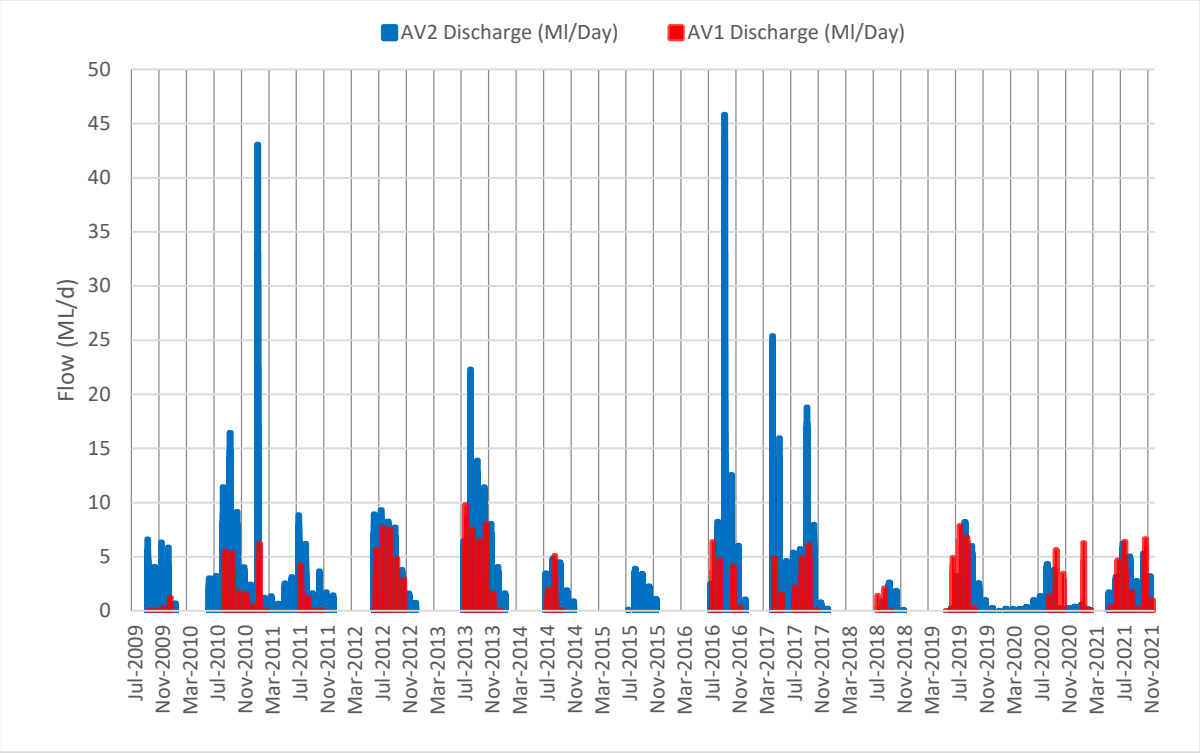

Figure 5-9 Total flow (by month) for the Anglesea River (AV1 & AV2) from 2009 to 2021

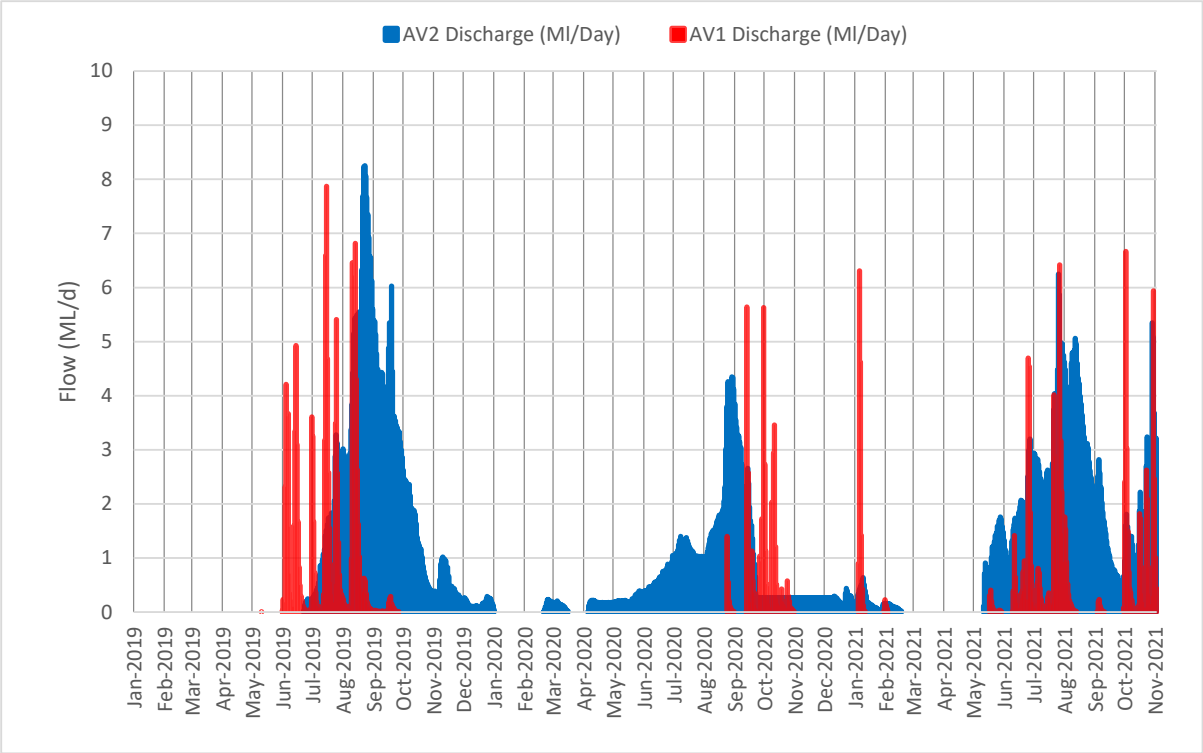

Figure 5-10 AV1 vs AV2 Baseflow Comparison 2019 to 2021

Table 5-1 Anglesea River Inter-Gauge Flow Differences

Monitoring Point	Comparison
Between monitoring points AV1 and AV2	Gaining conditions (i.e., where surface water flow gains occur as water travels downstream) are identified throughout the data record for these monitoring points. These stream gains are due to continued runoff and drainage of the catchment downstream of the upstream monitoring point. Again, this is as expected due to the increasing catchment size and runoff potential moving downstream. Short-term losing stream conditions were identified following prolonged dry periods. In these cases, rainfall recorded in the upstream monitoring point (AV1) probably infiltrated relatively dry ground and was subsequently attenuated in the swamp prior to reaching AV2.

5.8.1.3 Lower Anglesea River

At the lower reaches of the Anglesea River catchment in the region of the site and downstream, flows had previously been artificially supported by a 3-5 ML/day of approximately pH 7-8 water discharges from Alcoa's power station (EPA License EM32162), refer **Figure 2-3**. In addition to this discharge, the lower reaches of the Anglesea River received periodic baseflow (as throughflow) from the ASA formed in the permeable alluvial sediments deposited along the creek valley. The effect of Alcoa's alkaline buffering capacity, effectively masking the ongoing naturally occurring issues within the ephemeral river system for the majority of the last 50 years, along with peak flows from Salt Creek and Upper Anglesea River on the pH of the Estuary is clear on **Figure 2-3**.

5.8.2 Salt Creek

The total catchment area of Salt Creek is approximately 48.7 km^2 and primarily resides within Anglesea Heath, containing significant quantities of heathy woodland and swampy heath with peaty soils. For the purposes of this report, Salt Creek is described in two segments: Upper Salt Creek and Lower Salt Creek, **Figure 4-2**.

Geographically, Upper Salt Creek is defined as the reach above the marshland (near monitoring point SV4) with the lower reaches being defined from this point to monitoring point SV2 along the diversion channel. Flows occurring in the lower reaches have been modified over time as the mine footprint developed. A portion of the Salt Creek catchment has been modified in the 1960's whereby surface water in this location now runs into the mine void as opposed to Salt Creek or the diversion channel. The physical size of the mine void today, plus its local drainage area represents approximately 8% of the Salt Creek catchment, however the actual impact on the historical flows to Salt Creek would be dependent on the original topography and any additional catchment introduced by the diversion channel.

Monitoring point locations are shown in **Figure 5-7**. **Table 5-2** discusses inter-gauge flow differences across Salt Creek and flow history is shown in **Figure 5-11** (since 2009) and **Figure 5-12** (total period).

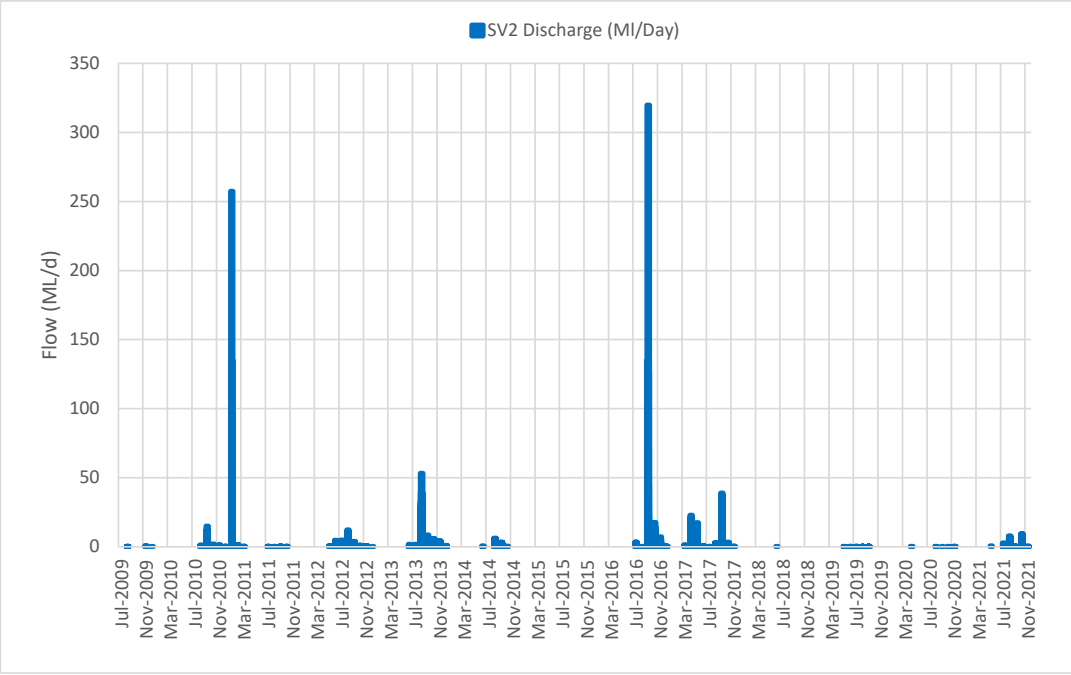

Figure 5-11 Total Flow (by month) for Salt Creek from 2009 to 2021

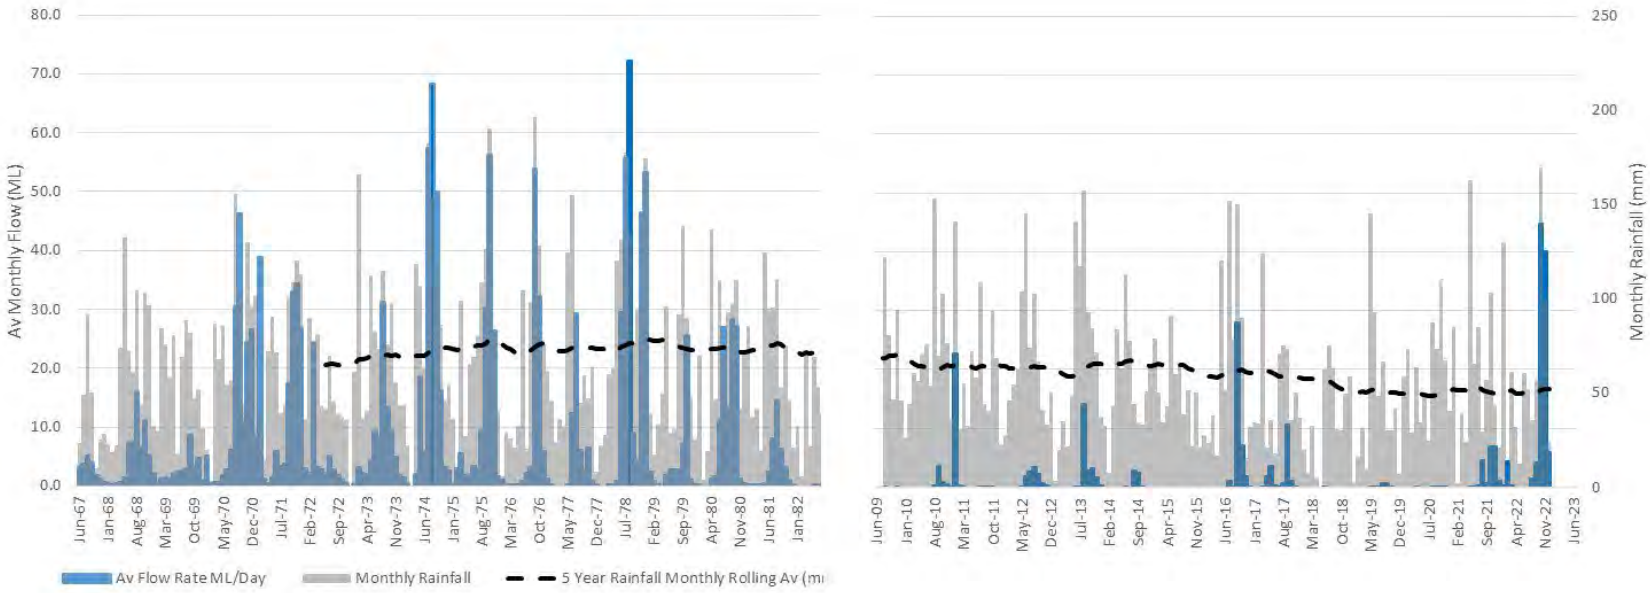

Figure 5-12 SV2 Historical Flow

Table 5-2 Salt Creek Inter-Gauge Flow Differences

Monitoring Point	Flow Description
Between monitoring points SV3 and SV1	• These monitoring points show primarily gaining stream conditions, often following large rainfall events. This is where surface water gains occur as water travels downstream, due to continued runoff and drainage of the catchment downstream of the upstream monitoring point (SV3). This is as expected given that catchment size increases in the downstream direction. Also, the likely addition of groundwater from perched watertables would contribute to gaining stream conditions. • Losing stream conditions occur temporarily, often at the commencement of the wetter winter period. This is possibly due to increased infiltration rates to relatively dry and unsaturated sub-surface soils.
Between monitoring points SV1 and SV4	• Short-term surface water flow losses were identified at downstream monitoring points, primarily due to rainfall runoff and infiltration subsequent to significant rainfall events. • Longer term surface water flow gains occur at SV4 (upstream of the swamp). Flow at this monitoring point continues subsequent to rain events and subsequent to flow upstream. This shows the increase in catchment size and as such, runoff potential, available to the downstream monitoring point (SV4). • A period of no flow was identified between January and April 2012.
Between monitoring points SV4 and SV2	• These monitoring points, situated upstream and downstream of the main swamp, predominantly show minor flow differences. They frequently show losing stream conditions, whereby surface water is attenuated by the swamp, either through evapotranspiration or infiltration. This results in less net flow passing through the down-swamp monitoring point (SV2). • Gaining stream conditions occur periodically during significant rain events, whereby there is more surface water flow at the down-swamp monitoring point compared with the up-swamp monitoring point. This results in cyclical flushing of the swamp and prolonged flow to the downstream monitoring point (SV2) compared with the up-swamp Anglesea River Catchment.

5.8.2.1 Upper Salt Creek

Upper Salt Creek, above the Breakfast Creek confluence (near SV1), is ephemeral; however, Breakfast Creek itself (a tributary to Salt Creek) appears to be the only section within the Anglesea River/Salt Creek catchment that appears to be perennial (GHD, 2013). This is supported by subsequent surface water monitoring reported by GHD (2016b).

Between SV1 and SV4, where the LEVF outcrops, baseflow is ephemeral with permanent pools of water (monitoring points SGP2-B and SV4). Mostly year around, these upper reaches appear to be mainly losing surface water reaches. **Figure 5-13** shows the flow differences in 2013 from upper catchment monitoring points (SV1 to SV3) to the lower reach (SV2).

5.8.2.2 Lower Salt Creek

Lower Salt Creek and its associated swamp (between SV4 and SV2) reports historical spring surface water flows with dry periods occurring at most other times of each summer (**Figure 5-12** and **Figure 5-13**). In this location, the Creek is confined to a more incised channel and is also inferred to be a potential losing stretch of surface water (GHD, 2013).

The lowest monitoring location in Salt Creek is along the diversion channel (monitoring point SV2), which generally only records flows during the winter months when high intensity and large duration rainfall events occur.

Total stream flow data at SV2 (Lower Salt Creek) ranges from 1967 to 1982 and 2009 to 2021 and is presented in **Figure 5-12**. This shows an average stream flow of 2,300 ML/year, ranging from years of no flow (e.g. 2015) to 9,000 ML/year (1978). In the latter period, flows are significantly lower than those observed in 1967 to 1982. **Section 5.8.3** explores the observed flow reduction further.

At SV2, daily flow exceeding 1 ML/day occurs approximately 35 percent of the time and completely dry conditions occur for approximately 50 percent of the time based on existing gauge records.

Lastly, it should be noted that only anecdotal data for flow exists between the period of 1983 and 2009, these are noted on **Figure 5-14**. Whilst no measured flow data exists between this period, a significant rainfall event (November 1995 of approximately 200 mm over 2 days), led to the overtopping of the Salt Creek diversion channel embankment and a volume of water estimated between approximately 3 and 4 GL entering the mine void (pers. com C. Rolland, 2016, former Alcoa Mine Manager).

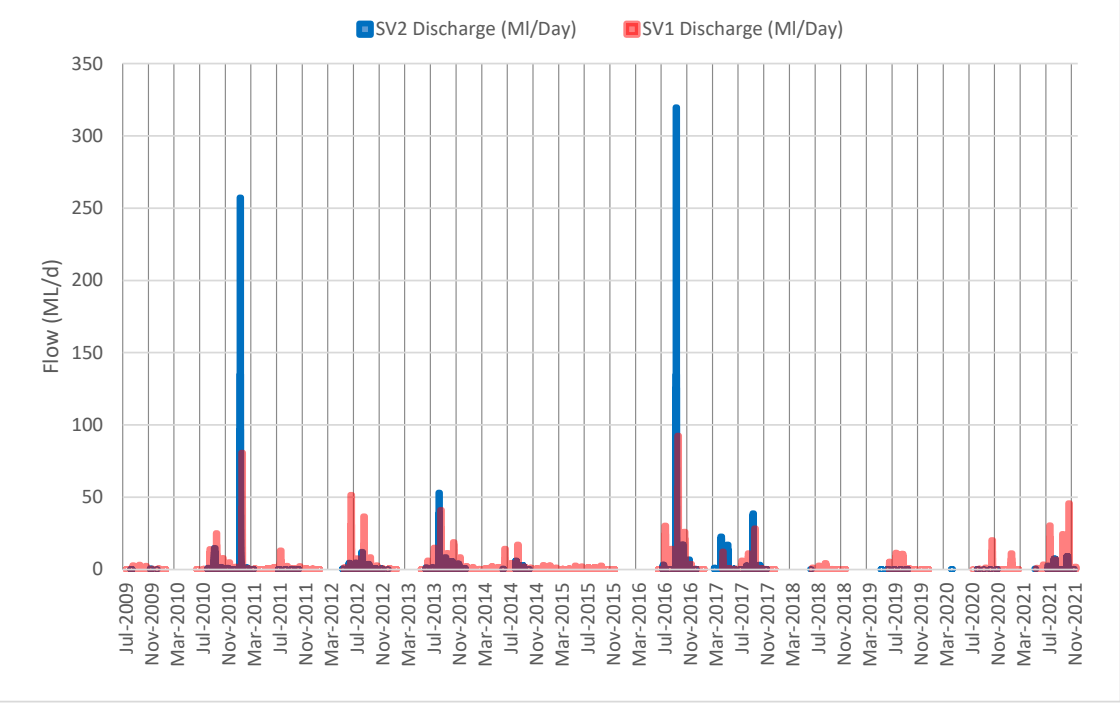

Figure 5-13 Upper Salt Creek Flow (SV1) vs Lower Salt Creek Flow (SV2)

5.8.3 Reduction in Surface Water Flows

Stream flows within the catchment have significantly declined since monitoring began in 1967, refer **Figure 5-14**. Numerous theories have postulated causes for this from the impact of climate change (such as decreased rainfall and increase in evapotranspiration) to an increase in water loss to underlying aquifers. This section explores these questions and outlines the most probably cause.

Firstly, the relationship between rainfall and runoff is not linear. Using over 120 years of catchment specific data, e.g. climate data from a gridded point adjacent the mine from the SILO database it is clear the region has seen significant shifts in climate. Between the 2 periods of 14-year available surface water flow that are available for comparison i.e. 2010 to 2023 and 1968 to 1981 there are vastly different rainfall statistics.

- Total rainfall between 1968 to 1982 was 9,994 mm an average of 714mm/yr.
- Total rainfall between 2010 to 2023 was 8,515mm with an average of 608mm/yr.

This means that during 2010 to 2023, the catchment received 1479 mm less rainfall when compared to 1968 to 1982. Using a high-level catchment yield calculator, this drop in rainfall represents a decline in more than 12,000[8] ML of surface water.

Furthermore, Chiew and Prossor (2011) suggest annual variations in rainfall are typically amplified as two- to three-times larger variations to annual runoff. So, a 10 percent reduction in rainfall typically leads to a 20 to 30% reduction in runoff. However, this rule of thumb does not always hold true especially in catchments dominated by large elevation differences and steep slopes (such as the Otway's). In fact, a study undertaken by (Potter and Chiew, 2011) in the Campaspe region of Victoria found that observed reduction in annual runoff during 1997–2008 was 59 percent lower compared to its long-term average despite rainfall only falling by 15 percent during this period.

For Salt Creek, a 16 percent reduction of rainfall (2010 to current c.f 1968 to 1981) has led to an 89 percent reduction in flow. Whilst this does seem severe and may indicate that additional water must also be losing from the catchment, it may not be unexpected considering the results from the Campaspe trial (Pott and Chew, 2011) and the fact that the majority of Salt Creek is located within a high relief catchment.

An additional study undertaken by (Saft *et al.,* 2015) looked at data from 228 catchments from south-eastern Australia (East Coast and Murray-Darling Basin water divisions) that are unregulated, relatively unimpaired, not nested, and with catchment areas between 50 and 2000 km^2. The study aimed to address whether annual rainfall-runoff relationships are significantly different during extended dry periods, compared with the historical norm and if so what catchment and climate characteristics cause these changes.

[8] Catchment Area = 11670 Ha; Catchment yield co-efficient of 7

The results found 79 percent of all catchments experienced a downward shift in the best-fit rainfall-runoff relationship during extended dry periods. This means that a persistent drought results in lowered runoff generation rates for similar rainfall amounts. Thus, in a sequence of years with reduced rainfall we would expect not only lower runoff due to the lower rainfall, but also less runoff than would be expected from the historical functional dependency of runoff on rainfall.

To relate the above with Salt Creek, and in recognition that following the millennial drought, multiyear rainfall from Wensleydale in 2005/06 was the 4th driest 2-year cumulative period on record (from 122 years); 2015/2016 was the 5th driest and 2018/19 was the 8th driest on record. In addition, the cumulative 5-year period 2005 to 2009 and 2014 to 2018 represent the two driest 5-year cumulative rainfall totals on record being 24 percent and 21 percent drier than each cumulative 5-year average between 1968 to 1981.

Therefore, if a 15 percent reduction in annual rainfall causes a 59 percent reduction in surface water flow in the Campaspe region of Victoria, it is entirely possible that >20 percent reduction in rainfall can lead to almost a 90 percent reduction in flow for a catchment with the relief characteristic of Salt Creek.

Notwithstanding the above, the purpose of this GIA, the data analysis, the groundwater pumping test, and the updated groundwater numerical model is to determine the risk of adverse impact associated with Alcoa groundwater extraction based on the best available data and science.

6 Conceptual Hydrogeological Model Overview

EHS Support developed a comprehensive Conceptual Hydrogeological Model, which has been reviewed and endorsed by the State appointed independent TRP and is provided in **Appendix A.** The following sections provide a focussed summary of the conceptual hydrogeological (and hydrological) conditions, relevant to the GIA.

In addition, continuous level loggers (data from some presented in **Appendix D**) and water quality are reported on a quarterly basis (example report presented in **Appendix G**). Observations that may lead to a potential change or increase understanding of hydrogeological processes are summarised in **Section 6.6**.

6.1 Climate

The Anglesea area is characterised by relatively high rainfall in the topographically elevated areas to the west, with decreasing rainfall across the lower northern and eastern areas. Long term average annual rainfall at the two closest rainfall gauging stations to the former mine range from 616 to 769 mm/year. Mean annual potential evaporation exceeds rainfall and has been measured at approximately 1,300 mm/year. Within the mine void, evaporative losses per year are estimated at 311 mm/year.

Over the last 120 years there have been three distinct climatic phases. Between 1900 and 1950, the region exhibited a drying climate, defined by average annual rainfall typically being lower than the LTA rainfall. Between 1950 and 1990, the region then experienced a strong wet period where above average rainfall fell for 27 out of 40 years. Recently, however, the rainfall surplus/deficit has again begun to fall with drier than average conditions dominating over the last 30 years.

Future median climate projections, relative to the current climate baseline, estimate that daily temperatures will increase, potential evapotranspiration will increase, and average annual rainfall and runoff will decrease.

6.2 Surface Water

The three main surface drainage features in the Anglesea area include Salt Creek and its associated swamps and tributaries, Upper Anglesea River/Marshy Creek and associated swamps and tributaries and the Lower Anglesea River. These waterways are ephemeral in natural, however, there are several non-groundwater fed, permanent pools that exist across its reach. These are recharged by overland/surface runoff and located in densely vegetated parts of the Alluvial Swamp system. Since surface water monitoring began in 1967, Salt Creek has experienced a significant decline is annual flow. This decline is primarily related to climate as outlined within this document.

At the lower reaches of the Anglesea River catchment in the region of the site and downstream, flows had previously been artificially supported by a 3-5 ML/day of approximately pH 7 water discharges from Alcoa's power station (EPA License EM32162). This ceased in 2016.

The surface water that flows in the catchment is retarded in Alluvial Swamps located in the mid and upper parts of the catchment. These alluvial swamps store and use (via evapotranspiration) significant volumes of water. The water that is stored in these systems is referred to as groundwater of the alluvial swamp aquifer (ASA). When the ASA storage is fully saturated and / or runoff exceeds the ASA's storage capacity, surface water flows begin.

The pH in the upper region of the Salt Creek catchment is generally around 5-7 and decreases to 3.5 to 4 in the mid to lower reaches due to a greater component of ASS which is readily oxidised. As with Salt Creek, acidity increases downstream in the Upper Anglesea River/Marshy Creek where the mid and lower reaches of the catchment contain more ASS which is readily oxidised. A similar trend is observed in electrical conductivity, where fresher water is reported in the upper catchments of Salt Creek and Anglesea River/Marshy Creek. In both sub catchments, the larger variation in EC seen in the downstream part of the catchment is likely due to surface water flows being retarded in the Alluvial Aquifer and allowing evapotranspiration to concentrate salts.

6.3 Catchment Acidity

Studies of acidity in the Anglesea River catchment have acknowledged the catchments naturally high pyrite and sulphur content as the main source of acidity or acid drainage. An acid sulfate soil assessment undertaken within the Anglesea swamp by Fiona Glover and Assoc Prof. John Webb (Report on Anglesea River Acid Sulfate Soil[9]) identified both potential PASS and AASS were present within the sediments. Wong et al., (2020), also found the catchment to contain high sulfur reserves from pyritic shales and siltstones, coal seams, tea tree swamps. The ASA also contains naturally occurring sulphide-bearing sediments, peat and coal. As the water level fluctuates in the ASA these sediments are exposed to air and oxidised in the vadose zone. This happens over and over again resulting in a build-up of leachable acid and metals. When the ASA becomes fully saturated (usually after a significant wet period), these oxidised sediments are mobilised resulting is low pH (acidic) water.

The Upper Anglesea River has experienced low pH events prior to Alcoa activities. A sampling point located at AV2 has consistently recorded pH between 2.5 and 4 since 1967. The Anglesea River estuary had previously been artificially supported by a 3-5 ML/day of approximately pH 7 water discharged from Alcoa's power station (EPA License EM32162) effectively masking any upstream low pH events. This discharge ceased in 2016. This along with the introduction of Cooroogarah Park (circa 1983) and the management of the estuary mouth have contributed to the variability in water quality seen in the Estuary over time.

A good statistical correlation exists between rainfall surplus and deficit trends and catchment acidity (pH) indicating that climate (rainfall) and catchment pH have some dependency. 12 km further south at Airies Inlet, Distillery Creek (a tributary of Painkalac Creek) has also reported frequent low pH conditions (Surf Coast Shire, 2006). Therefore, climatic drivers as opposed to anthropogenic factors (such as groundwater pumping) are understood to be the main reason for the low pH conditions experienced within the catchment.

[9] Download Thesis (hdp-au-prod-app-barwonwater-yoursay-files.s3.ap-southeast-2.amazonaws.com)

6.4 Surface Water and Groundwater Interactions

Previously geological and hydrogeological evidence has indicated that the swamps and marshlands that make up the shallow unconfined ASA acts like a perched water system, that is water in the ASA finds it very difficult to interact (leak or receive baseflow) with underlying aquifers. This conceptualisation is supported by a number of lines of evidence which are summarised below:

- A review of all available exploration geological bore logs (22 logs) that were located either within or adjacent to the ASA shows that an average thickness of 27.7m (max = 86m; min = 2.4m) of either clay or silt (e.g. low permeability material) that separates the base of the alluvial / swamp sediments in which surface water flows to the next most permeable layer underlying the surface water systems.
- Laboratory testing of some of these low permeability materials indicated that the average vertical hydraulic conductivity was 0.0002 m/d with an average porosity of 41 percent. To put this in context, assuming a minimum thickness of 2.4m existed between the base of the swamp sediments and the next most permeable formation, surface water would need to be present for 5.6 years for water to leak though this barrier. As we know, the surface water ways are ephemeral, and this driving head of water is rarely there for more than a few months at a time.
- Throughout the marshland areas several permanent water pools have been mapped (AGP1-B, AGP2 and ASP7). Stable and radioactive isotopes obtained within these pools indicate that they are not in direct connection with the underlying aquifers and therefore not baseflow dependant. At these locations there is an upward gradient. If the gradient was to reverse, as the impermeable base of the ASA inhibits baseflow, there is no reason to suggest it won't do the same and inhibit leakage.
- All ASA monitoring bores have shown a stable trend over the last 10 years with no impact seen in either system despite Alcoa extraction up to 2016, more recent aquifer pumping tests undertaken by Alcoa, and also aquifer pumping tests undertaken by Barwon Water between 2009 and 2012.
- Most large rainfall events exceeding 40mm have resulted in an immediate increase in groundwater levels within most ASA monitoring locations. This indicates that direct rainfall recharge is the dominant driver of recharge to the ASA. Within the ASA, the steepest decline of groundwater levels occurs over spring and summer when episodic rainfall events are absent (such as spring and summer of 2011/12; 2013/14; 2015/16; and 2019/2020). This similar correlation is not commonly observed in unconfined aquifers surrounding the ASA such as the outcropping UEVF, DBG and Boonah Formation. As evapotranspiration is highest during spring and summer, this suggests that evapotranspiration and throughflow is the most likely cause of water loss from the ASA.

6.5 Hydrogeology

A complex series of aquifers and aquitards exist beneath the coal mine and former power station. A summary from the shallowest to deepest is provided below.

In addition to the hydrogeological units described below, the mine void acts as a hydrogeological control; for the local catchment, the mine void acts as a groundwater sink. Prior to the exposed coal being covered, seepage faces after heavy rain were observed near the main coal and basal clay interface leading into the mine void. As coal is unsaturated, its anticipated that its permeability has increased and within the vicinity of the mine, groundwater that would normally be held in the Boonah Formation, now has an easier migration path. This flux will continue to be high until the main coal seam becomes saturated.

The Alluvial Swamp Aquifer (ASA) is the shallowest and described as unconfined comprising alluvial sediments and organic clay and peaty mix. This aquifer exists within Marshy Creek and Salt Creek and appears to be disconnected from the underlying sediments of the DBG, Boonah Formation and the UEVF by clay located at its base. Hydrographic analysis as well as water chemistry using stable and radioactive isotopes also suggest limited potential for surface water and groundwater interactions to occur. A review of the aerial imagery along with ecological reports (Ecology Australia 2007, 2011, 2012, 2013a,b) indicates swamp vegetation and associated ecology has persisted and suggests that the ASA has remained saturated over the long term.

The Demons Bluff Formation consists of siltstone, clay, sandstone and minor coal seams. At the former power station site, the DBG is extends from the surface to ~10 mbgl and thickens and dips towards the southeast. The Boonah Formation underlies the DBG, is ~25m thick and consists of clean sandstone with minor shale, clay and coal. The mine void acts as a groundwater sink and most observation bores screened in the DBG surrounding the mine are unsaturated. In the vicinity of the mine, the only monitoring bore that was saturated was DBG MB06 with an average TDS of 2,770 mg/L. This bore is installed within the backfilled overburden material and as such is not representative of the native aquifer. Permeability tests undertaken within this formation are highly variable with an average horizontal hydraulic conductivity (0.1 m/d, from slug tests) and vertical hydraulic conductivity of $1x10^{-4}$ m/d, from laboratory analysis). The recharge potential of outcropping sediments is low as evidenced by a lack of watertable response after heavy rainfall.

Underlying the DBG is the UEVF which is represented by multiple aquifers occurring as sand lenses separated by aquitards (clay and coal). In the upper half, there is significantly more clay and coal, whilst more permeable sand lenses exist near the base. These basal sand lenses were the target of Alcoa's historical extraction. Pre mine levels suggested the potentiometric surface (groundwater pressure) for the UEVF lower sands found >180mbgl at the mine was ~4m AHD. This means that is a bore were to be drilled to >180m at this location, the standing water level in that bore would rise to 4m AHD or near ground surface. Individual sand sequences above this within the UEVF showed slightly lower potentiometric surfaces the shallower the sand lenses occurred. Vertical permeability testing of these clays and coal indicated an average vertical hydraulic conductivity of $1x10^{-4}$ m/d. Analysis of the pumping test Stage 1 results suggest the horizontal hydraulic conductivity is 1.3 m/d and a storativity of $4x10^{-4}$. Groundwater quality is variable within shallower sand sequences with the TDS within the upper sands is variable ranging from 168 mg/L (UEVF MW07) to 3,470 mg/L (UEVF MW04) with a median

concentration of 889 mg/L. This provides evidence that these lenses may be discontinuous or impacted by the mine void. In the lower sands, during the groundwater pumping test pH ranged from 6.3 to 6.7 with a mean of 6.5. The TDS ranged from 741 to 1,660 mg/L which is consistent with historical ranges reported prior to May 2021, of between 830 to 1,313 mg/L.

The MEVF underlies the UEVF and generally consists of 30-40m of mudstone and siltstone, but also has minor sand and gravel lenses as well as thin brown coal layers. It has been previously modelled as a leaky aquitard as depressurisation impacts have been observed in some deep Alcoa UEVF observation bores whilst pumping has been occurring from nearby the LEVF extraction bores. However, a recent bore assessment program involving down hole camera and wireline logging was undertaken by Alcoa to identify bores with potential integrity issues or those that may cross screen aquifers. In 2021, several at-risk bores were identified and decommissioned. Since the restarting of the LEVF extraction by Barwon Water in early 2022, no impacts have been recorded in the Alcoa UEVF deep observation bores indicating that potential cross aquifer interactions have been mitigated (refer to **Section 7** for further discussion on cumulative pumping risks).

The LEVF underlies the MEVF and forms a confined to semi-confined aquifer (in the upper parts of the catchment) across the region and consists of unconsolidated micaceous silts, carbonaceous clays, silty clays, thin brown coal seams and fine to coarse-grained sands and gravels. Below the coal mine site, the LEVF is up 200 m thick where aquifer material occurs within geological synclines. Geologically, this unit represents the Pebble Point Formation and, prior to Barwon Water groundwater extraction in the area, was artesian at the site. Groundwater TDS in the LEVF is fresher than that observed in the UEVF. GHD (2013) reported that groundwater salinity had been measured between approximately 500 to 900 mg/L TDS. The aquifer parameter data suggests hydraulic conductivities of up to 2.77 m/day can occur in individual sand horizons.

6.6 Observation from the Ongoing Quarterly Monitoring

As part of the current site reporting objectives, continuous groundwater level and water quality are reported on a quarterly basis. This was initiated for the UEVF groundwater pumping test which commenced on 13 May 2021, and was completed on 8 December 2021. The November 2024 Quarterly report is attached as **Appendix G**. Key observations noted from this report include:

- Groundwater pressure for the upper part of the UEVF aquifer (approximately 40m to 140m depth) show no impact of pumping (**Figure 6-1**). This increase in trend in this part of the aquifer is attributed to the long-term pumping of the sump which intersected the upper sand lens.
- The rate of recovery observed in UEVF MB1, UEVF MB 2 and UEVF MB 5 (downgradient of the waterbody and closest to the historical sump location) show a partial response to pit waterbody level fluctuations (**Figure 6-1**). This does not imply a direct connection, rather as the pit waterbody fills, the aquifer is compressed, and the rate of recovery varies slightly due to compressibility and storativity characteristics of the aquifer.
- Groundwater levels in the shallower aquifer generally show gradual to stable trends over the cooler months (March to October) and declines over the warmer months (associated with higher evapotranspiration) or when there has been low rainfall in the preceding months (**Figure 6-1**). This continues to support rainfall and evapotranspiration as the key drivers for groundwater behaviours in this area.

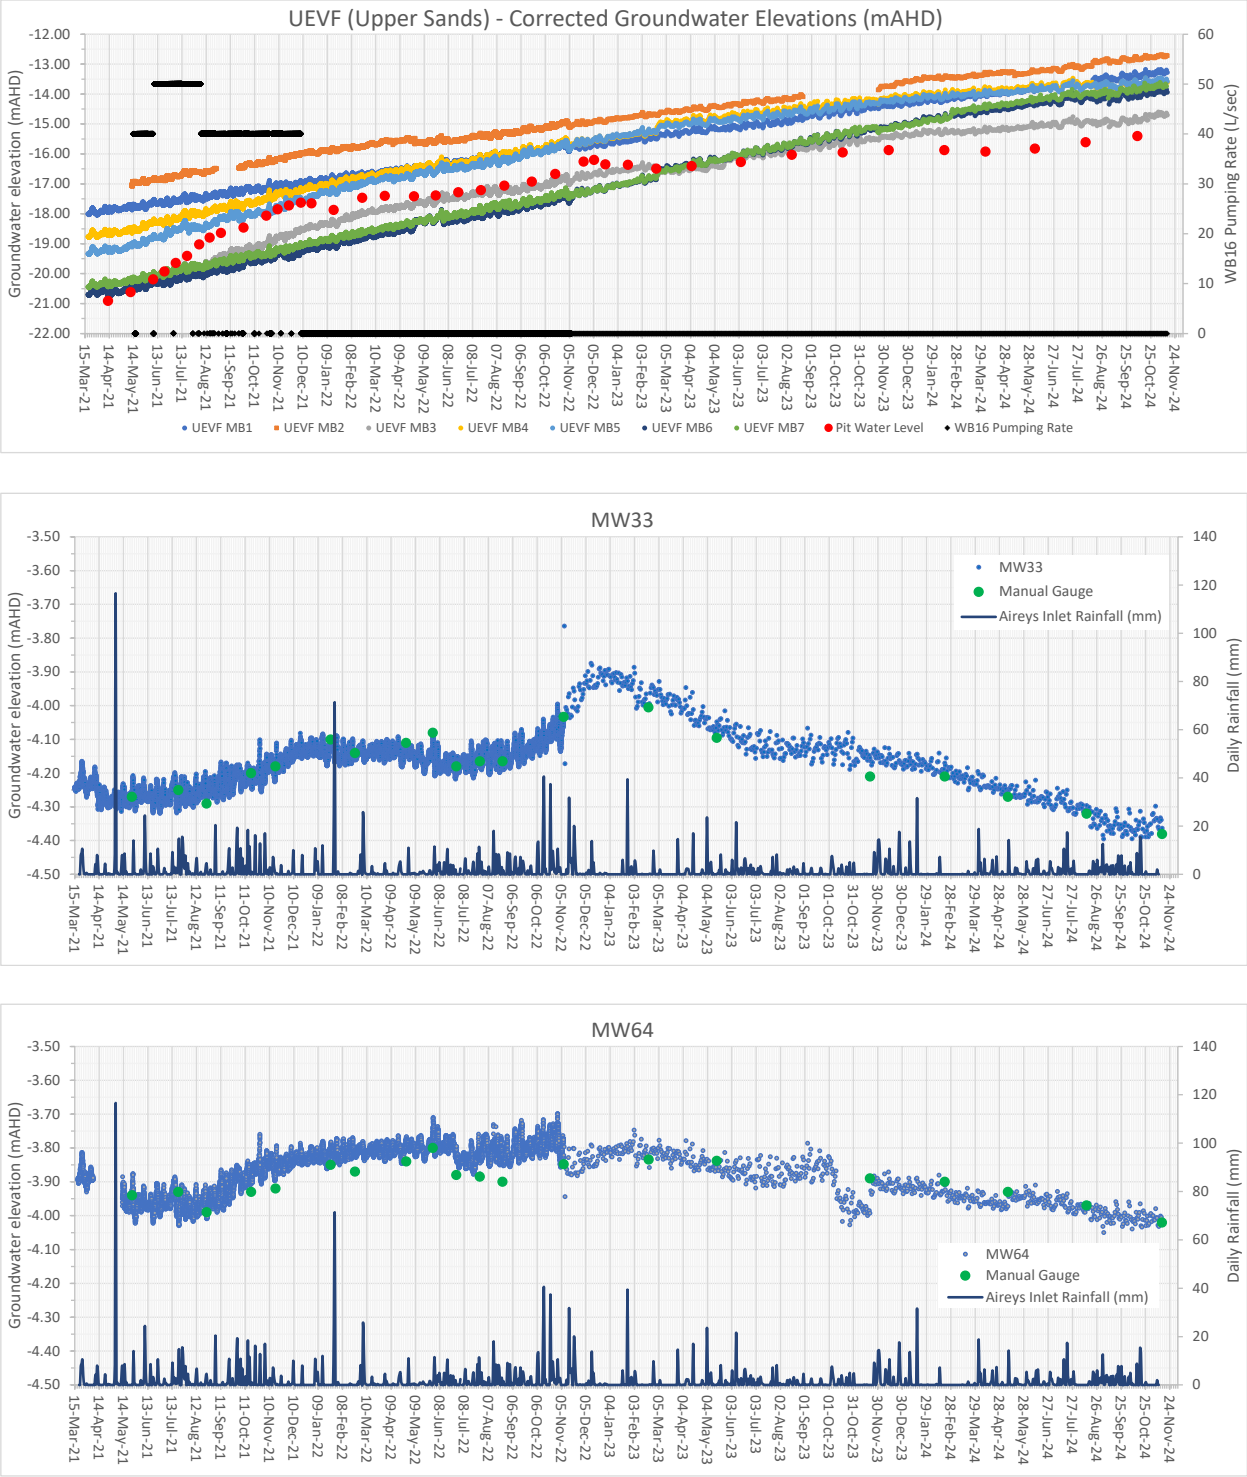

Figure 6-1 Selected Hydrographs from the Continuous Water Level Monitoring

7 Numerical Groundwater Flow Model

The updated Anglesea Groundwater Model - Numerical Model Development and Calibration Report is provided in full as **Appendix E**. A summary of the findings is provided below.

7.1 Overview

Barwon Water investigated and developed the Anglesea bore field, an urban groundwater supply, between 2007 and 2010 in response to severe water shortages at that time. Development of the bore field was supported by a series of field and desktop investigations, including the original 2009 numerical groundwater model developed by GHD, that evaluated potential bore field impacts. Following this, a Bulk Entitlement (BE) for bore field operation was issued by the Victorian Government in June 2009 based on those preliminary investigations. In 2013, the 2009 numerical groundwater model was updated following a series of pumping tests undertaken by Barwon Water between 2011 and 2012. A five-yearly review of data and modelling is required under the BE following bore field operation, which occurred in late 2019, and is again under review in 2024; Barwon Water rely on the most updated numerical groundwater model, currently referred to as the 2024 Anglesea groundwater model, for bore field sustainability and impact assessments.

In 2020 Southern Rural Water (SRW) approved a 12-month UEVF groundwater pumping test for Alcoa to assess the sustainability and effects of groundwater abstraction for filling of the mine void over a proposed period of approximately 10 years. Hydrogeological data from this pumping test along with refinement of geological layers from recent drilling near the mine supported further development and calibration of the 2024 Anglesea groundwater model. Note that Barwon Water and Alcoa both use the same calibrated 2024 Anglesea groundwater model for supporting groundwater licence requirements.

The 2024 Anglesea groundwater model has been subject to rigorous independent peer review by a regulator appointed Technical Review Panel has two main objectives:

- Support Barwon Water's Anglesea bore field planning, management and approvals works under the BE process, specifically:
  - Barwon Water are required to periodically update their Anglesea groundwater model that underpins the Anglesea bore field BE and use it to re-assess aspects of bore field sustainability, details of which are outlined in the main body of this GIA report.
- It is intended that GHD, with subconsultant Groundwater Logic, will develop and apply predictive model scenarios for Barwon Water's BE review purposes, using the developed history-matched models documented in **Appendix E**.
- Support Alcoa/EHS Support for Alcoa's mine closure and rehabilitation planning and management works, specifically:
  - Support Alcoa's license application to SRW for potential long-term groundwater abstraction for filling of the mine void. Specific issues to be addressed using the 2024 Anglesea groundwater model are outlined in the main body of this GIA report.
- It is intended that Alcoa/EHS Support will develop and apply predictive model scenarios for Alcoa's purposes, using history-matched models (refer **Appendix E**).

The 2024 Anglesea groundwater model is based in a minor sense on the earlier modelling of GHD (2013) but is a wholly new model using a new numerical code, layer structure, and parameterisation schemes, and modern methods of history matching to historical observation data. It was built and operates in a stochastic framework that recognises input observation data and model parameter uncertainties.

The intent of using this approach is that the recognised input uncertainties are carried through to their effects on model forecasts and their uncertainty, and therefore their effects on water management decision-making.

The model simulates flux-conserved groundwater and surface water flow and interactions between the two systems. It also simulates the post-Alcoa coal mine closure mine void water body balance, including its interaction with groundwater and other surface water systems. The model history-matching process therefore uses a range of surface water and groundwater data of wide-ranging types, including mine void water levels, to inform (constrain) model parameters. It also uses derivative observations such as water table depth-frequency curves, flow-frequency curves, pumping-induced drawdown trends, and vertical hydraulic gradients.

The intent of employing these wide-ranging observation types is, to the extent possible, to minimise related model forecast uncertainties such as the uncertainty in potential effects from groundwater use on the shallow water table (in swamps), surface water systems, and acid generation risks.

Two-hundred and sixty-three history matched model realisations, each with widely varying parameters, were selected from an ensemble of five hundred. For predictive scenario modelling purposes, a smaller, more manageable number of model realisations was selected for application in that case (e.g., the top 150 models of higher history match quality).

History match quality across these models is generally good, for groundwater levels in deeper bores, water table depths in shallow bores, mine void water body levels, and surface water flows. There are however of course exceptions to this which are discussed in the main body of this GIA report. Several points for further investigation and analysis, aimed at improving history-match quality at specific sites in specific ways, are also identified and discussed.

The model developed and framework used provide a sound basis for ongoing use of the 2024 Anglesea groundwater model in the context of rigorous model forecast and uncertainty assessment.

7.2 Predictive Model Scenarios/Quantities of Interest

Both the updated Alcoa Conceptual Hydrogeological Model (**Appendix A**) and the updated Anglesea groundwater model have been independently peer reviewed by the regulator appointed Technical Review Panel (TRP) to ensure that the model represents current best conceptual understanding, technical practice, and meets the model defined objectives (refer **Appendix E**). This has ensured a comprehensive and robust basis for predictive scenario assessment as part of this GIA.

The modelled scenario and historical climatic data (and climate change projections) along with the Quantities of Interest (QoIs) for assessing any potential impacts or defining other investigations that may be required are discussed in the sections below. It should be noted in the QoIs (refer **Table 7-6**)

drawdown and absolute heads will be extracted as this will enable a comparison between the potential impact as a result from extraction under a certain climate reference period to that of the calibrated observations.

7.2.1 Climate Change

The Guidelines for Assessing the Impact of Climate Change on Water Availability in Victoria DELWP (2020) were used to identify an approach for applying climate change scenarios for temperature, potential evapotranspiration, rainfall, runoff and groundwater recharge to be used across Victoria for assessing the impact of climate change on water availability.

7.2.2 Reference Period

The reference period outlined in DELWP (2020), i.e., Reference Period 1 – post-1975 to 2023, will be used to inform future projections whilst considering potential future climate change effects. The use of a post-1997 reference period was considered however due to significant model run time and the statistical similarities of annual rainfall from the SILO (Point Patched Dataset (PPD) location shown on **Figure 4-5** between post-1975 and post-1997 to 2023s, refer below for rainfall, this second reference period was not warranted.

- Rainfall post 1975 = 643 mm/yr
- Rainfall post 1997 = 622 mm/yr

Note: whilst the rainfall observations from the two periods above are relatively similar, observations between the two periods that contain surface water flow data (that is 1968 to 1982 and 2010 to 2023) are significantly different, refer **Table 2-3.**

7.2.2.1 Applying Climate Change Projections

Whilst it is anticipated that any groundwater application will just be for the period required to fill the mine void, the models' predictive capability will begin January 2023 (year 1) and will run until February 2066 (year 44) which will be decades longer than any potential groundwater application. Monthly stress periods will be incorporated up until February 2040. Between March 2040 and 2066, stress periods will reduce to seasonal, being 4 stress periods per year (March to May, June to August, September to November, and December to February).

Simulations involved using a climate projection obtained from the Stochastic Climate Library (SCL) tool within the stochastic weather library[10] for the climate reference station within and adjacent the model domain. Whilst each predictive groundwater scenario contains 150 unique projections (to bound uncertainty), one realisation from the SCL was applied, rather than 150 unique realisations for each of the 150 history-matched groundwater models. This approach removes "noise" from the model outputs so that the effects from any proposed pumping can be more readily discerned from randomness in

[10] https://toolkit.ewater.org.au/Tools/SCL

climatic inputs. To ensure this stochastically generated dataset was appropriate, a scenario without any climate change applied to the climate reference period (1975 - 2023) was used to check that the simulated average annual recharge map derived from the SCL outputs was sufficiently like that from the average rate mapping from the history-matched models over this same period. This is how the single SCL realisation was chosen, i.e., the one (of 150) that most closely resembled historical annual average recharge across the model domain.

The projections based upon data obtained from the post-1975 reference period and projected changes between 1995 and the year of interest were scaled according to the RCP8.5 (conservative) global climate model (GCM); that is, the 10, 50, and 90 percentile forecasts for the stochastic dataset for rainfall and evaporation were scaled down by the amounts for the climate projection scenarios (medium, high) as shown in **Table 7-1** and would be applied directly to the climate sequence obtained from the method above. Forecasting projections based on post-1997 reference period used the 10, 50, and 90 percentile forecasts for the stochastic dataset for rainfall and evaporation.

Note: The DELWP (2020) guidelines recommends analysis of the low, medium and high scenarios, projected from the post-1975 reference period. The low climate change scenario was excluded from this assessment as this would have resulted in even lower potential risks and as the risk assessment is designed to be conservative, the use of a low climate change scenario was excluded.

Table 7-1 Projected Change in Average Annual Rainfall, Runoff, and Potential Evapotranspiration Relative to 1995 % for the Otway Coast as Presented in DELWP (2020b)

	Rainfall (RCP8.5)			Runoff (RCP8.5)			Evapotranspiration (RCP8.5)		
Projection	**2020**	**2040**	**2065**	**2020**	**2040**	**2065**	**2020**	**2040**	**2065**
Medium	-2.0%	-3.6%	-5.8%	-4.0%	-7.2%	-15.8%	2.0%	3.7%	6.4%
High	-6.5%	-11.7%	-19.0%	-14.1%	-25.3%	-41.9%	2.9%	5.3%	9.5%

Table Notes:
These are applicable to post 1975 reference period.

7.2.3 Defining Surface Water and Groundwater Historical Reference Period

While the project site contains a comprehensive set of climate data, and despite 27 years of daily surface water data, there is a gap for Salt Creek flow data between 1982 to 2009. Between 1967 and 1982 surface water data at SV2 was collected during the wettest period on record for the catchment, and then from 2010 to current, which is representative of some of the driest conditions observed (refer **Figure 5-4**). Historical trends and relationships between surface water flow and rainfall have resultingly been difficult to establish.

To maintain the use of the precautionary principal, the surface water conditions (monthly flow and no flow days) experienced between the period January 2010 to 2023 will therefore be used as "the historical reference period", as any adverse impact beyond this as a result from a proposed groundwater license application will clearly be unacceptable. Flow statistics are presented in **Table 7-2** to **Table 7-4**.

It is worth noting however that ultimately, in practice, comparison between model forecast conditions with historical conditions is done using modelled equivalents of the historical data – noting that the model is history-matched to the data most strongly over the 2010-2023 period of data availability.

Table 7-2 Annual Surface Water Flow Statistics – February 1975 to December 2023

7.2.4 Predictive Groundwater Modelling Scenarios

Table 7-5 outlines the scenarios undertaken. The outcomes of the scenario modelling have informed the broader groundwater impact and risk assessments associated with the Alcoa groundwater license application; note, Barwon Water have a current licensed Bulk Entitlement, and are also currently in the process of reviewing their future Bulk Entitlement. Barwon Water have informed Alcoa that for their assessment a Bulk Entitlement of 7GL per year for 5 years, every 5 years should be considered appropriate.

Note: To satisfy Section 40 of the Water Act 1989, from the scenarios modelled, the results presented in this application have isolated Alcoa's pumping impact from other cumulative impact contributors such as Barwon Waters Bulk Entitlement and climatic factors, also presented in this application. Specifically the results shown for Alcoa's pumping only impact presented in the following sections of this assessment, were determined numerically by the difference between Scenario 2 and Scenario 3.

Fundamental to each scenario are the Quantities of Interest (QOIs). The QOIs form a key prediction or model outcome from a specified model scenario, with a predefined spatial and temporal setting, that is relevant to assessing the likelihood and consequence of a causal pathway element representing a hazard. These are presented in **Table 7-6**. Fundamental to these QOIs are the following terminology definitions:

- "Drawdown" refers to the magnitude of change in groundwater level in response to a given development scenario, as measured relative to the case without the development change (i.e., the "baseline" or "null" scenario, which is that without the groundwater pumping that is tested in the development scenario).
- "Absolute head" is used herein to refer to observed and/or modelled groundwater levels and/or depths (i.e., not change in groundwater levels). Absolute head is used in the QOI definitions to present the modelled drawdown (scenario difference) in a more physically meaningful context. In this case, we assess whether modelled drawdown induces a decline in groundwater levels below the observed and/or modelled historical range (from the historical comparison period described earlier); this will differ across the various climatic model inputs (rainfall, evaporation, and hence recharge and runoff; see the above section on "Applying climate change projections").

Table 7-5 Model Scenarios

Scenario	Climate Scenario	High Level Rationale
Scenario 1		
No Groundwater Extraction ("baseline Scenario 1" or "null" scenario)	Reference Period 1 - Medium[1]	Estimate the natural recovery of the mine void over time with only natural groundwater inflow, and rainfall (overland flow and direct) to counter evaporation.
	Reference Period 1 - High[1]	
Scenario 2		
Baseline Scenario 2 Bulk Entitlement Operation for LEVF. The BE has been defined by Barwon Water	Reference Period 1 - Medium[1]	Modelled results (drawdown and absolute heads) to assess potential impacts for existing Barwon Water BE from the LEVF.
	Reference Period 1 - High[1]	
Scenario 3		
Groundwater extraction from WB16 at 1500ML/yr for 10 years Bulk Entitlement Operation for LEVF[2].	Reference Period 1 - Medium [1]	Modelled results (drawdown and absolute heads) to estimate the potential cumulative impacts resulting from dual operation of UEVF and LEVF extraction.
	Reference Period 1 - High[1]	
Scenario 4		
Mine void fills in 12 months	Reference Period 1 - Medium [1]	Estimate the movement of mine void water into the surrounding aquifers as a result of a Catastrophic Flood Filling event which will cause the mine void to fill up within 12 months.

Table Notes:

1 Applied to the post-1975 reference period.

2 Barwon Water pumping @ 7GL/year for 5 years, then off for 5 years. This cycle will be repeated once, totalling a model run for 20 years, after which, no further pumping assumed.

Table 7-6 Quantities of Interest

Quantities of Interest	Where and How It Will Be Defined or Measured
1 Drawdown at High Value Groundwater Dependent Ecosystems and within the mapped marshlands of the ASA. High Value GDEs is represented by the mapped marshy sediments founds in the alluvial channels located across the catchment and shown on **Figure 4-2** and **Figure 5-8**.	Risks (consequence and likelihood) to high value GDEs was assessed using the framework outlined in the Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems (DELWP 2015) as well as likelihood of exceedance as presented in Peeters LJM and Middlemis H 2023[1] (table 4, pg. 42). Consequence was determined by the modelled median prediction (P50) whilst the method presented in Peeters LJM and Middlemis H., 2023[1] was used to determine the likelihood. Of these 150 realisations, the median value (e.g., P50) represented the consequence of the impact, whilst the P10 and P90 outputs represented the bounds of probability (or likelihood). Both drawdown and historical dry season water table depth were used to assess risk by adopting these consequence criteria: • Minor consequence if median modelled drawdown or change in historical dry season water table depth is <0.1m; • Moderate consequence if modelled drawdown change in historical dry season water table depth is > 0.1 m but < 2m; and • Significant (high) consequence if modelled drawdown change in historical dry season water table depth is > 2 m. Note: Drawdown of 0.1m is the lowest resolution the numerical model is designed for, refer, Table 5-3 of GHD Rev 7. The rationale for using seasonal variability in addition to drawdown is that reductions in seasonal water table depth range may pose risks to GDEs – i.e., some species may require periodic root zone saturation, flushing, or moisture access via capillary action from the water table. This metric however must be interpreted in the context of drawdown because absolute watertable depths arguably matter more to GDEs than seasonal variability – if a GDE cannot access the water table because it has been lowered below the root zone throughout the year (due to climatic factors), then seasonal watertable fluctuations below the root zone throughout the year would have no bearing on GDE health or risks because the water table that the GDE typically seasonally accesses is no longer accessible; for reference, "Seasonal watertable depth range" here means the difference between the 95th percentile and 5th percentile exceedance values as measured over the time periods assessed. These percentile values represent percentages of time over which watertable depth values are exceeded – i.e., the 5th percentile reflects the deepest groundwater depth values that are exceeded only 5% of the time (typically occurring in summer), whilst the 95th percentile represents the shallowest water table depth values that are exceeded over 95% of time (typically occurring in winter and spring). This range metric represents typical seasonal watertable range or variability. Differences in this modelled seasonal range metric between the model with WB16 pumping and the case without pumping, along with differences from historical 2010-2023 conditions are presented. This is termed change in historical dry season water table depth.
2 Increase in future acid generating events at SV2 and AV2 as a result of increased flow cessation days.	The natural or artificial lowering of water tables, below those typically experienced under natural conditions along with the frequency and seasonal fluctuations, can lead to acidification of soil and groundwater in areas where these sub-surface environments contain appreciable amounts of sulfide minerals (Shand et al, 2018). To assess the risks of acid generating events, a similar approach to protect high value GDEs was used; that is, using the groundwater model to establish consequence limits for the altering of the seasonal variability of the water table as well as the flow characteristics of the surface water systems. Specifically: • Minor consequence if the seasonal variability of the ASA water table (WTOB1 and WTOB2) is no more than 0.1m greater than the historical range (2010 to 2023) caused by Alcoa's simulated pumping AND other effects such as climate and other groundwater users, OR there is no reduction in annual zero-flow days relative to the 2010-23 historical period. • Moderate consequence if the seasonal variability of the ASA water table (WTOB1 and WTOB2) is greater than 0.1m and less than 1m greater than the historical range (2010 to 2023) caused by Alcoa's simulated pumping AND other effects such as climate and other groundwater users, OR there is between zero and 10% reduction in mean annual zero-flow days relative to the 2010-23 historical period. • Significant consequence if the seasonal variability of the ASA water table (WTOB1 and WTOB2) is more than 1m greater than the historical range (2010 to 2023) caused by Alcoa's simulated pumping AND other effects such as climate and other groundwater users, OR there is greater than 10% reduction in zero-flow days relative to the 2010-23 historical period. As outlined in QOI 1, the method presented in Peeters LJM and Middlemis H., 2023[1] was used to determine the likelihood by using the P10 and P90 outputs as the bounds of probability (or likelihood). Note: As mentioned above 0.1m drawdown is the lowest resolution the numerical model is designed for, refer, Table 5-3 of GHD Rev 7. This combined with natural water level fluctuations within the ASA which on a daily timescale can often exceed 0.1m (**Figure 6-1),** and >2.5m annually **(Appendix D),** means acid generating processes at a scale finer than 0.1m cannot be numerically assessed. As a result and to add an extra layer of conservatism to the assessment, seasonal variability of the water table as well as the flow characteristics of the surface water systems has also been incorporated in this process. This combined with the fact that the modelled Alcoa results in this GIA are conservative in nature, satisfies Section 40 of the Water Act 1989
3 Reduction in surface water flows from Marshy Creek and Salt Creek flows into the Anglesea River Estuary.	Water quality aside (assessed in QOI 1 and 2), flows from Salt Creek and Marshy Creek are important to maintain stage heights in the Anglesea River Estuary. To ensure the model predictions and resulting risk adequately considers potential changes to surface water flows, the absolute flow rate difference as a percentage against flow from the baseline period was used to inform the risk of modifying catchment inflows to the Anglesea River Estuary. Specifically, a moderate or higher consequence is identified when: • Low consequence. o No reduction in zero flow days from the historical period 2010-2023. o Where AV2 and SV2 mean annual absolute flow rate difference measured against the baseline period is less than 5%. • Moderate consequence: o Between zero and 10% reduction in mean annual zero-flow days relative to the 2010-23 historical period, OR

Quantities of Interest	Where and How It Will Be Defined or Measured
	o Where AV2 and SV2 mean annual absolute flow rate difference measured against the baseline period is greater than 5% but less than 20%, as a result of the pumping (in isolation from climate and other groundwater users) AND where the mean annual absolute flow rate measured against the historical period (2010 – 2023) has a difference greater than 5% but less than 20%, as a result of the "cumulative" pumping and climatic factors. • Significant (high) consequence: o Greater than 10% reduction in zero-flow days relative to the 2010-23 historical period; OR o Where AV2 and SV2 mean` annual absolute flow rate difference measured against the baseline period is greater than 20%, as a result of the pumping (in isolation from climate and other groundwater users) AND where the mean annual absolute flow rate measured against the historical period (2010 – 2023) has a difference greater than 20%, as a result of the "cumulative" pumping and climatic factors. Measured at AV2 and SV2. As outlined in QOI 1, the method presented in Peeters LJM and Middlemis H., 2023[1] was used to determine the likelihood by using the P10 and P90 outputs as the bounds of probability (or likelihood).
4 Migration of mine void water beyond the licenced mine lease area and into the underlying UEVF Upper Sands as part of any proposed future extraction from the UEVF.	As the mine void fills, there is potential for pit (surface) water to infiltrate into the unsaturated mine sediments surrounding the mine, which may in turn create conditions where water rock geochemical interactions can occur. To assess this water particle migration was undertaken. To capture the most conservative scenario (e.g., the case that provided the greatest potential mine void water to migrate into the surrounding environment, the mine void is assumed to be filled in 12 months). If as a result of this activity there is more than a 10% (P10) chance of a particle of water (determined by Mod-Path3DU or flux source tracing e.g., FlowSource code (Foley and Black, 2013)) migrating from the mine void to nodal points placed at the boundary of the mine lease area as well as in the top of the UEVF Upper Sands over the modelled extraction period, a mass balance of acid-generating materials within the pit overburden/backfill material vs. natural DBG may be undertaken.

7.3 Results

For a complete list of modelled results, refer to **Appendix F**.

7.3.1 Mine Void Water Body Recovery Profile

The mine void water level stage height was modelled under the various scenarios presented in **Table 7-5** to better understand the recovery profile of the mine void water body, which is presented in **Figure 7-1**. Firstly, it should be noted that the applied evaporation rate for the developing water body is based on the historical (post-Alcoa closure 2016 to 2023) rate of mine void water body recovery. This means that as the mine void fills, evaporation is likely underestimated at later times and hence and especially for the no pumping scenario, modelled fill times will be underestimated (modelled to fill quicker). Therefore, for this scenario (i.e., no pumping scenario), and due to this uncertainty, the modelled P5 uncertainty bounds have been presented. This uncertainty is not considered critical for the proposed groundwater amendment, more for the final MRCP, and as such it is proposed that in future iterations of the model, this will be addressed.

The current uncertain result indicated that for the scenario of left to fill naturally, under a medium climate change scenario, the mine void water body would fill in approximately three decades (26 years). However, and as discussed above, this time is estimated to be quicker due to the uncertainty surrounding modelled open waterbody evaporation. Once a steady state profile is achieved, the modelled water level would fluctuate by up to +2 m annually, although smaller variations of about 0.5m (volume equivalent of ~500 ML) annually are more frequent.

For the scenario where groundwater is extracted from the UEVF at a rate of 1.5 GL/yr for 10 years, (Alcoa only Pumping, **Figure 7-1**), and the basis of the proposed license amendment, the mine void water body fills in just under 10 years. Full is defined by water level >+4.0m AHD as per the current mine earthworks design. Once the UEVF extraction ceases, a small amount of mine void water appears to infiltrate into the remaining unsaturated surrounding sediments to fill pore spaces before slowly reaching the maximum model height of 5.67m AHD. After this point, water is removed from the model. As presented in **Section 7.3.5**, particles of water that move from the mine void water body back into the aquifer, never migrate beyond the mine lease boundary.

For the cumulative scenario (UEVF at a rate of 1.5 GL/yr for 10 years, plus the operation the LEVF Bulk Entitlement), the mine void water level is modelled to take significantly longer. The reasons for this additional time will be explored further by Alcoa in conjunction with Barwon Water, with this potential issue being important to understand for the final MRCP, but not considered critical for the proposed groundwater amendment application.

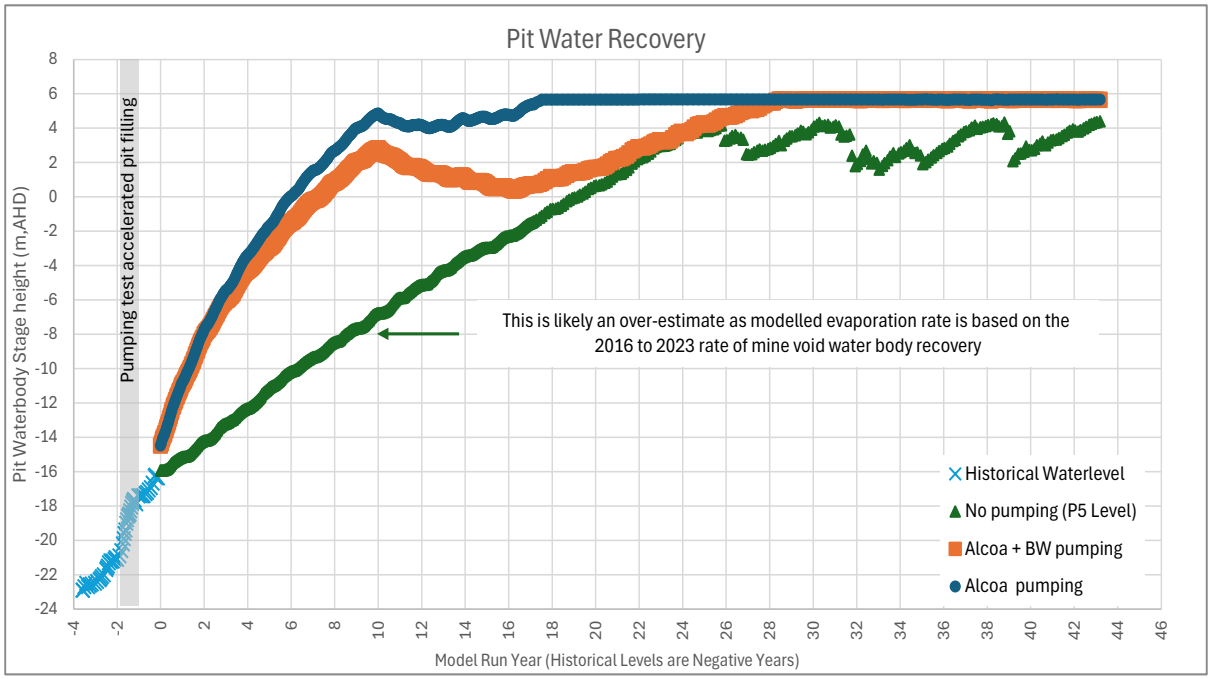

Figure 7-1 Modelled Pit Water Body Behaviour

7.3.2 Drawdown at High Value Groundwater Dependent Ecosystems

7.3.2.1 Median Climate Change

The modelled change in water table depth caused by Alcoa simulated pumping in isolation of all other effects is presented and discussed below, specifically:

- **Table 7-7** presents the modelled P10, P50 and P90 maximum drawdown within the modelled dataset at all ASA observation bores. Graphically, these are shown in **Appendix F**.
- **Figure 7-2** to **Figure 7-4** present modelled water table depth changes at observation bores located within the ASA caused by Alcoa's simulated pumping in isolation of all other effects such as climate and other groundwater users (i.e., "drawdown"). Error bars show model uncertainty over the 10th to 90th percentile range. Negative y-axis values indicate lower (deeper) water table levels than the baseline model (e.g., no pumping), while positive y-axis values indicate higher values.
- **Figure 7-5** presents the maximum annual average drawdown over any decadal or longer forecast period measured across the P10, P50, and P90 modelled water table drawdown across defined zones of Potential Acid Sulphate Soils (ASS/PASS) within the ASA and swamplands.
    - The maps in the left column of **Figure 7-5** represent the modelled water table drawdown due to Alcoa pumping, averaged across each zone. The value that is averaged is actually the maximum annual average drawdown over any decadal or longer forecast period.
    - The maps in the right column of **Figure 7-5** represent the modelled water table depth difference from historical (2010-2023) conditions, accounting for the effects of climate and all groundwater users.
    - The upper and lower row of maps present the upper (90th percentile) and lower (10th percentile) model uncertainty limits.
    - The three colours used to symbolise each map are classed according to the consequence thresholds defined in **Section 7.2**, – i.e., high, moderate, and low consequence.
- **Figure 7-6** presents modelled water table depth changes at bores WTOB1 (lower Salt Creek swamplands; left half of the chart) and WTOB2 (lower Anglesea River swamplands; right half of the chart).
    - The blue data series markers represent the modelled change in water table depth caused by Alcoa's simulated pumping in isolation of all other effects such as climate and other groundwater users. Drawdown here is measured as the maximum annual average drawdown over any decadal or longer forecast period (periods are shown along the x-axis).
    - The red data series markers on the other hand show the difference in water table depths between the forecast model and the historical model over the 2010-2023 period, accounting for the effects of climate and all groundwater pumping. This metric is often termed "cumulative drawdown", as it includes the cumulative effect of Alcoa's pumping along with climatic effects and the effects of other groundwater users. The red data series represent changes in dry (summer) period water table depths relative to historical (2010-2023) conditions, as measured at the higher (deeper) 10th percentile depth exceedance value over each of the time-period blocks shown along the x-axis; this figure represents risks to the typical seasonal low point on the water table hydrograph, which is presumably important to GDEs that require seasonal water table access when there is little to no rainfall.

  - Both the red and blue data series need to be interpreted in the context of one another – a model that simulates "drawdown" when measured as a difference between a model with groundwater pumping and another without pumping does not mean that groundwater levels will be lower than they were historically. This is particularly important in this case, because of the long history of groundwater usage and mine dewatering by Alcoa between 1968 and 2016. Under these conditions the groundwater system is in the process of a long-term recovery in pressure, hence future "drawdown", at least around the Alcoa mine site, is likely to delay groundwater pressure recovery rather than lower groundwater pressure. Note this is pressure within the lower sands of the UEVF and is not reflected within surface aquifers.
  - Error bars show model uncertainty over the 10th to 90th percentile range. Negative y-axis values indicate lower (deeper) water table levels than either the model without Alcoa pumping (blue data series) or the historical period (red data series), while positive y-axis values indicate higher values.
- **Figure 7-7** presents modelled seasonal water table depth range changes for Salt Creek swamplands (WTOB1) and Anglesea River swamplands (WTOB2). These also form a GDE risk metric; therefore, consequence thresholds are shown behind this plot. "Seasonal water table depth range" here means the difference between the 95th percentile and 5th percentile exceedance values, as measured over the time periods shown along the x-axis on **Figure 7-7**. These percentile values represent percentages of time over which water table depth values are exceeded – i.e., the 5th percentile reflects the deepest groundwater depth values that are exceeded only 5 percent of the time (typically occurring in summer), whilst the 95th percentile represents the shallowest water table depth values that are exceeded over 95 percent of time (typically occurring in winter and spring). This range metric represents typical seasonal water table range or variability. Differences in this modelled seasonal range metric between the model with Alcoa pumping and the case without pumping (blue data series), along with differences from historical 2010-2023 conditions (red data series), are presented in this plot. Other details follow:
  - The marker symbols (data series) plotted are presented for observation bore WTOB1 in the left half, and for observation bore WTOB2 in the right half.
  - Each marker is labelled along the x-axis by a model time-period over which the water table depth range statistics are taken. A variety of these periods is presented to show that modelled changes in water table depth seasonality, and changes that are due to Alcoa pumping, can vary over time.
  - Each marker has error bars shown, which represent the lower (10th percentile) to upper (90th percentile) model uncertainty limits as measured across the 150 model realisations.

The results listed in **Table 7-7** and presented in **Figure 7-2** to **Figure 7-5** (as well as **Appendix F**) show that of the 44 years modelled, the median (P50) drawdown for all observation bores within the ASA and marshlands have modelled potential drawdown <0.1m. This results in a low consequence of impact as defined by the Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems (DELWP 2015).

When considering uncertainty (used in the assessment of Risk, **Section 7.3.6**), the P10 limit (e.g. takes into consideration 90% of model realisations) suggests at WTOB2 (**Figure 7-2**) and P7/P7B a maximum potential drawdown of 0.11m is forecast. As the median drawdown here is much lower than this, it would indicate very few of the 150-model realization indicate this 1cm exceedance. It is important to note that historical groundwater monitoring at this location shows no evidence of historical pumping related impacts (refer **Table 2-3**, and **Section 2.3**).

In addition to the above, **Figure 7-5** suggests the only areas simulated to experience drawdown from the proposed Alcoa only pumping scenario to water table levels below historically observed depths are two small tributaries in the middle Anglesea swamplands and the upper-mid sections of the Anglesea river swamplands (see the circled areas in **Figure 7-5**). Most other areas of the ASA and swamplands are simulated to experience similar or slightly shallower water table depths than historical conditions (blue areas on the right column of maps in **Figure 7-5**), despite drawdown from Alcoa pumping (orange areas on the left column maps).

With respect to cumulative impacts, **Figure 7-6** shows that the modelling indicates a high likelihood of low consequence to water table drawdown from Alcoa pumping for bores WTOB1 and WTOB2 (blue data series). When these (low) risks are considered with reference to water table change from historical (2010-2023) conditions (red data series), there is also generally low (to no) consequence because water table levels, particularly at bore WTOB2, are for the most part higher (i.e., shallower) over the forecast model period than those over the historical period.

Regarding modelled seasonal water table depth range (**Figure 7-7**), the modelling shows that the simulated Alcoa groundwater pumping has caused insignificant to no reduction in the seasonal water table depth range over the forecast model period (blue data series; low consequence) at both WTOB1 and WTOB2. Even at the 90th percentile model uncertainty limit, the error bars indicate that this metric never breaches the moderate consequence threshold for either bore. **Figure 7-7** also shows that when forecast seasonal water table depth ranges are compared with those from the historical (2010-2023) period (red symbols), they are always higher (greater seasonal variability) than in the historical period for bore WTOB2, despite the insignificant potential water table depth changes arising from Alcoa's pumping. WTOB1 shows modelled water table depths that are at times deeper than those in the historical 2010-2023 period, though this is not due to drawdown from Alcoa's proposed pumping schedule.

Table 7-7 Modelled Maximum Drawdown Over a 10 Year Period (Medium Climate Change) from the Alcoa Only Pumping scenario at all ASA Observation Bores

Bore ID	Drawdown (m, P90 Max)	Drawdown (m, P50 Max)	Drawdown (m, P10 Max)
P1	0.00	-0.02	-0.06
P13B	-0.02	-0.04	-0.07
P16	0.00	0.00	-0.01
P17	0.00	-0.01	-0.03
P18	-0.01	-0.02	-0.04

7.3.2.2 High Climate Change

The modelled change in watertable depth caused either by Alcoa simulated pumping in isolation of all other effects as well as accounting for the effects of climate and all groundwater pumping users is presented and discussed below, specifically:

- **Table 7-8** presents the mmodelled P10, P50 and P90 maximum drawdown within the modelled dataset at all ASA observation bores. Graphically, these are shown in **Appendix F**.
- **Figure 7-8** to **Figure 7-10** present modelled water table depth changes at observation bores located within the ASA caused by Alcoa's simulated pumping in isolation of all other effects such as climate and other groundwater users (i.e., "drawdown"). Error bars show model uncertainty over the 10th to 90th percentile range. Negative y-axis values indicate lower (deeper) water table levels than the baseline model (e.g., no pumping), while positive y-axis values indicate higher values.
- **Figure 7-11** presents the maximum annual average drawdown over any decadal or longer forecast period measured across the P10, P50, and P90 modelled water table drawdown across defined zones of ASS/PASS within the ASA and swamplands.
    - The maps in the left column of **Figure 7-11** represent the modelled water table drawdown due to Alcoa pumping, averaged across each zone. The value that is averaged is actually the maximum annual average drawdown over any decadal or longer forecast period.
    - The maps in the right column of **Figure 7-11** represent the modelled water table depth difference from historical (2010-2023) conditions, accounting for the effects of climate and all groundwater users.
    - The upper and lower row of maps present the upper (90th percentile) and lower (10th percentile) model uncertainty limits.
    - The three colours used to symbolise each map are classed according to the consequence thresholds defined in **Section 7.2**, i.e., high, moderate, and low consequence.
- **Figure 7-12** presents modelled water table depth changes at bores WTOB1 (lower Salt Creek swamplands; left half of the chart) and WTOB2 (lower Anglesea River swamplands; right half of the chart).
    - The blue data series markers represent the modelled change in water table depth caused by Alcoa's simulated pumping in isolation of all other effects such as climate and other groundwater users (i.e., "drawdown"). Drawdown here is measured as the maximum annual average drawdown over any decadal or longer forecast period (periods are shown along the x-axis).
    - The red data series markers on the other hand show the difference in water table depths between the forecast model and the historical model over the 2010-2023 period, accounting for the effects of climate and all groundwater pumping. This metric is often termed "cumulative drawdown", as it includes the cumulative effect of Alcoa's pumping along with climatic effects and the effects of other groundwater users. The red data series represent changes in dry (summer) period water table depths relative to historical (2010-2023) conditions, as measured at the higher (deeper) 10th percentile depth exceedance value over each of the time-period blocks shown along the x-axis; this figure represents risks to the typical seasonal low point on the water table hydrograph, which is presumably important to GDEs that require seasonal water table access when there is little to no rainfall.
- Both the red and blue data series need to be interpreted in the context of one another – a model that simulates "drawdown" when measured as a difference between a model with Alcoa pumping and another without pumping does not mean that groundwater levels will be lower than they were historically. This is particularly important in this case, because of the long history of groundwater usage and mine dewatering by Alcoa between 1968 and 2016.

Under these conditions the groundwater system is in the process of a long-term recovery in pressure, therefore future "drawdown", at least around the Alcoa mine site, is likely to delay groundwater pressure recovery rather than lower groundwater pressure.

- Error bars show model uncertainty over the 10th to 90th percentile range. Negative y-axis values indicate lower (deeper) water table levels than either the model without Alcoa pumping (blue data series) or the historical period (red data series), while positive y-axis values indicate higher values.

The results listed in **Table 7-8** and presented in **Figure 7-8** to **Figure 7-10** (as well as **Appendix F**) show that in all model predictions, the median (P50) drawdown predictions are all <0.1m across the ASA and marshlands. There are minor exceedances when the upper uncertainty level is considered, which are:

- Minor drawdown exceedances are observed at observation bore WTOB2 (**Figure 7-8**, mid reaches of Marshy Creek) in 9 out of 44 years modelled. Maximum drawdown modelled is 0.22m.
- Minor drawdown exceedances are observed at observation bore P1 (**Figure 7-9**, upper reaches of Salt Creek) 25 years into the model timeline. Note: There are no mapped GDE's at this location.
- Minor drawdown exceedances are observed at observation bore P8 (**Figure 7-10**, mid reaches of Marshy Creek) in 2 out of 44 years modelled.
- Minor drawdown exceedances are observed at observation bore P13B (**Figure 7-10**, upper reaches of Marshy Creek) in 9 out of 44 years modelled. Note: There are no mapped GDE's at this location.

With respect to **Figure 7-11**, this also confirms drawdown along Salt Creek remains a low consequence whilst confirming the results above; i.e., under a high climate change scenario the Lower-mid Anglesea River swamp and two small tributaries upstream of Salt Creek confluence (circled in **Figure 7-11**) are modelled to experience moderate consequence drawdown levels (due to Alcoa pumping alone).

With respect to cumulative impacts, **Figure 7-12** shows that the modelling indicates a high likelihood of low consequence to water table drawdown from Alcoa pumping for bores WTOB 1 and WTOB2 (blue data series).

Table 7-8 Modelled Maximum Drawdown Over a 10 Year Period (High Climate Change) from the Alcoa Only Pumping scenario at all ASA Observation Bores

7.3.3 Modelled Future Acid Generating Events

7.3.3.1 Median Climate Change

As presented in **Table 7-6**, water table depth, its variability, and changes to stream flow zero-flow days is used to inform the risk of increasing acid generating events.

Figure 7-13 presents the seasonal variability of the ASA water table (WTOB1 and WTOB2) relative to the 2010-2023 historical period, as per below:

- Seasonal water table depth range metrics are shown to the right, recalling that more than 0.1m change greater (lower water table) than the historical range (2010 to 2023) results in moderate or high consequence.
- Blue markers show the range change due to Alcoa pumping, as measured against the “no Alcoa pumping” case.
- Red markers show the cumulative range change, due to all factors including pumping, climate, and post-mining recovery. These are measured as change from the historical 2010-2023 period.

Figure 7-14 presents the percent change in annual zero-flow days relative to the 2010-2023 historical period, as per below:

- The percent change in annual zero-flow days metrics are shown to the right. Recalling any change greater than 0 percent (dryer) than the historical range (2010 to 2023) results in moderate or high consequence.
- Blue markers show the range change due to Alcoa pumping, as measured against the “no Alcoa pumping” case.
- Red markers show the cumulative range change, due to all factors including pumping, climate, and post-mining recovery. These are measured as change from the historical 2010-2023 period.

The results from **Figure 7-13** indicate that all model estimates fall within the low consequence band in terms of Alcoa’s component of drawdown (blue markers). In cumulative terms, either climate or potential cumulative impacts associated with the BE causes a risk of seasonal water table variability range both higher and lower than historical conditions, however Alcoa’s proposed pumping is not forecast to appreciably influence this.

The results from **Figure 7-14** suggest forecast zero flow days at SV2 and AV2 are generally the same as or fewer than over the historical 2010-2023 period, at the P10 and P50 uncertainty limits; most model estimates fall into the low consequence band, although in years 11-20 are modelled to fall into the moderate consequence band (at SV2 and AV2). At the upper end (lower likelihood uncertainty estimate - P90) however, the modelling estimates that zero flow days, as compared to the 2010-2023 historical period, could at times fall into the high consequence band at AV2, primarily in years 11-20, under the cumulative scenario.

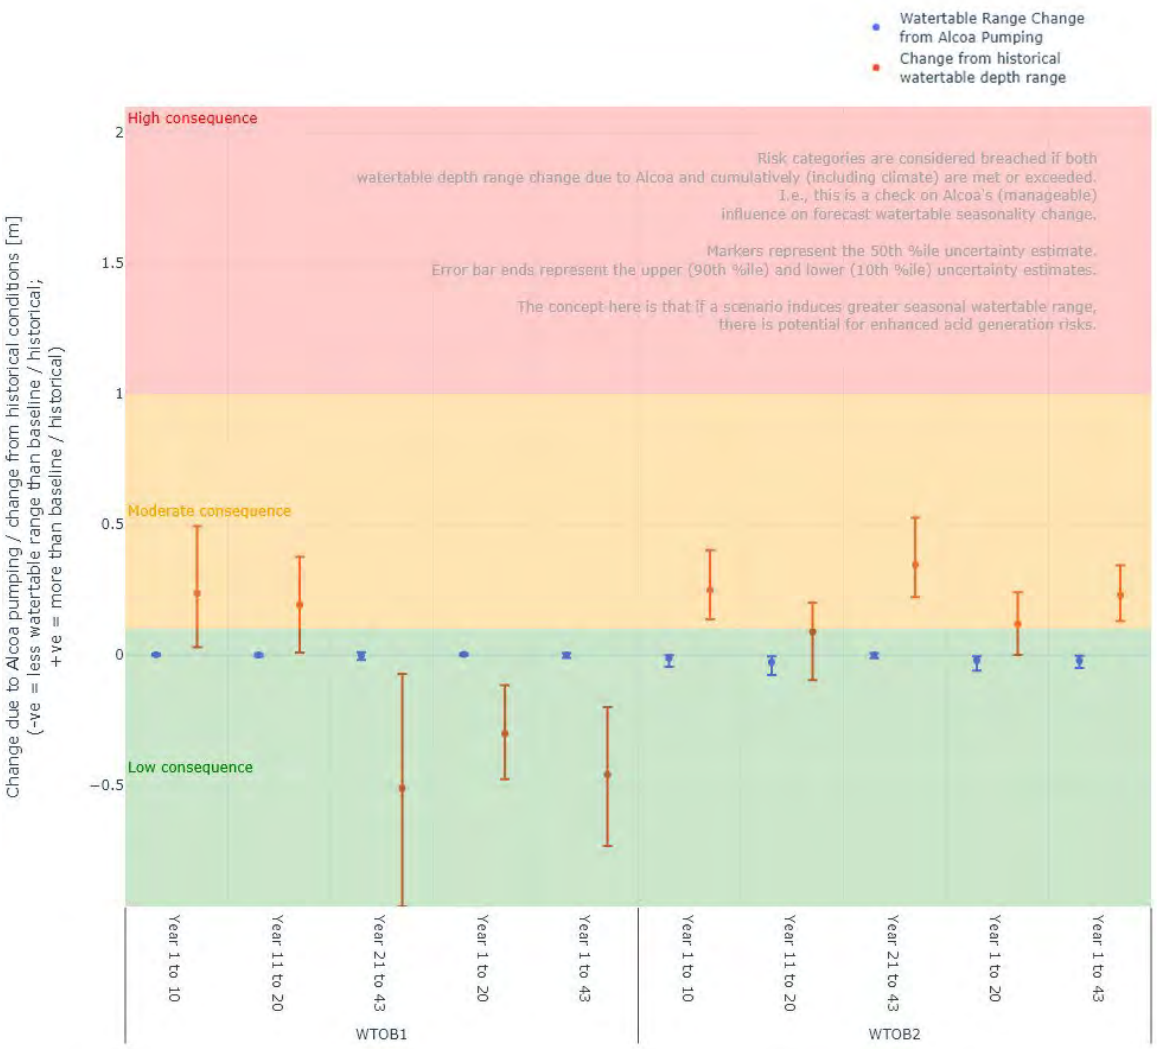

Figure 7-13 Median Climate Change – Seasonal Variability of the ASA Watertable (WTOB1 and WTOB2) Relative to the 2010-2023 Historical Period

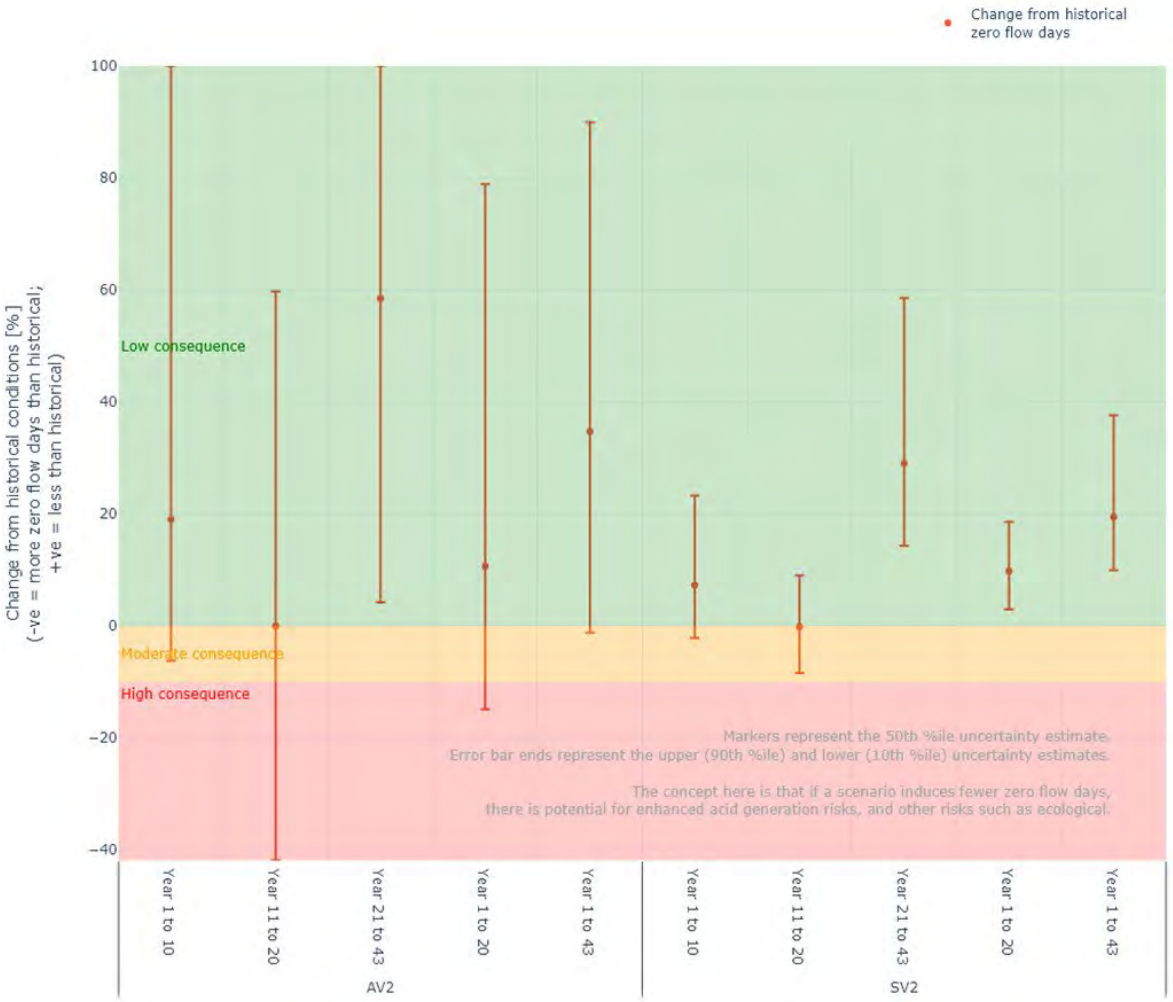

Figure 7-14 Median Climate Change – Percent Change in Annual Zero-flow Days Relative to the 2010-2023 Historical Period

7.3.3.2 High Climate Change

As resented in **Table 7-6**, water table depth, its variability, and changes to stream flow zero-flow days is used to inform the risk of increasing acid generating events.

Figure 7-15 presents the seasonal variability of the ASA water table (WTOB1 and WTOB2) relative to the 2010-2023 historical period, as per below:

- Seasonal water table depth range metrics are shown to the right. Recalling more than 0.1m change greater (lower water table) than the historical range (2010 to 2023) results in moderate or high consequence.
- Blue markers show the range change due to Alcoa pumping, as measured against the “no Alcoa pumping” case.
- Red markers show the cumulative range change, due to all factors including pumping, climate, and post-mining recovery. These are measured as change from the historical 2010-23 period.

Figure 7-16 presents the percent change in annual zero-flow days relative to the 2010-23 historical period, as per below:

- The percent change in annual zero-flow days metrics are shown to the right. Recalling any change greater than 0 percent (dryer) than the historical range (2010 to 2023) results in moderate or high consequence.
- Blue markers show the range change due to Alcoa pumping, as measured against the “no Alcoa pumping” case.
- Red markers show the cumulative range change, due to all factors including pumping, climate, and post-mining recovery. These are measured as change from the historical 2010-2023 period.

The results from **Figure 7-15** indicate that all model estimates fall within the low consequence band in terms of Alcoa’s component of drawdown (blue markers). In cumulative terms, risk of seasonal water table variability range both higher and lower than historical conditions, however Alcoa’s proposed pumping is not forecast to appreciably influence this.

The results from **Figure 7-16** suggest forecast zero flow days at SV2 and AV2 fall into the high consequence band, except at AV2 at the upper uncertainty interval at times, when zero flow days are like or fewer than over the historical period. AV2 also exhibits a much greater range of (and uncertainty in) potential zero flow periods than does SV2, likely due to SV2 being closer to the significant historical stresses of the Alcoa mine. Model parameters relating to its behaviour are therefore more informed by mine void management and progression than those in the AV2 catchment; either way, the modelling indicated climate, rather than Alcoa pumping, has the biggest impact on flow and seasonal water table fluctuations.

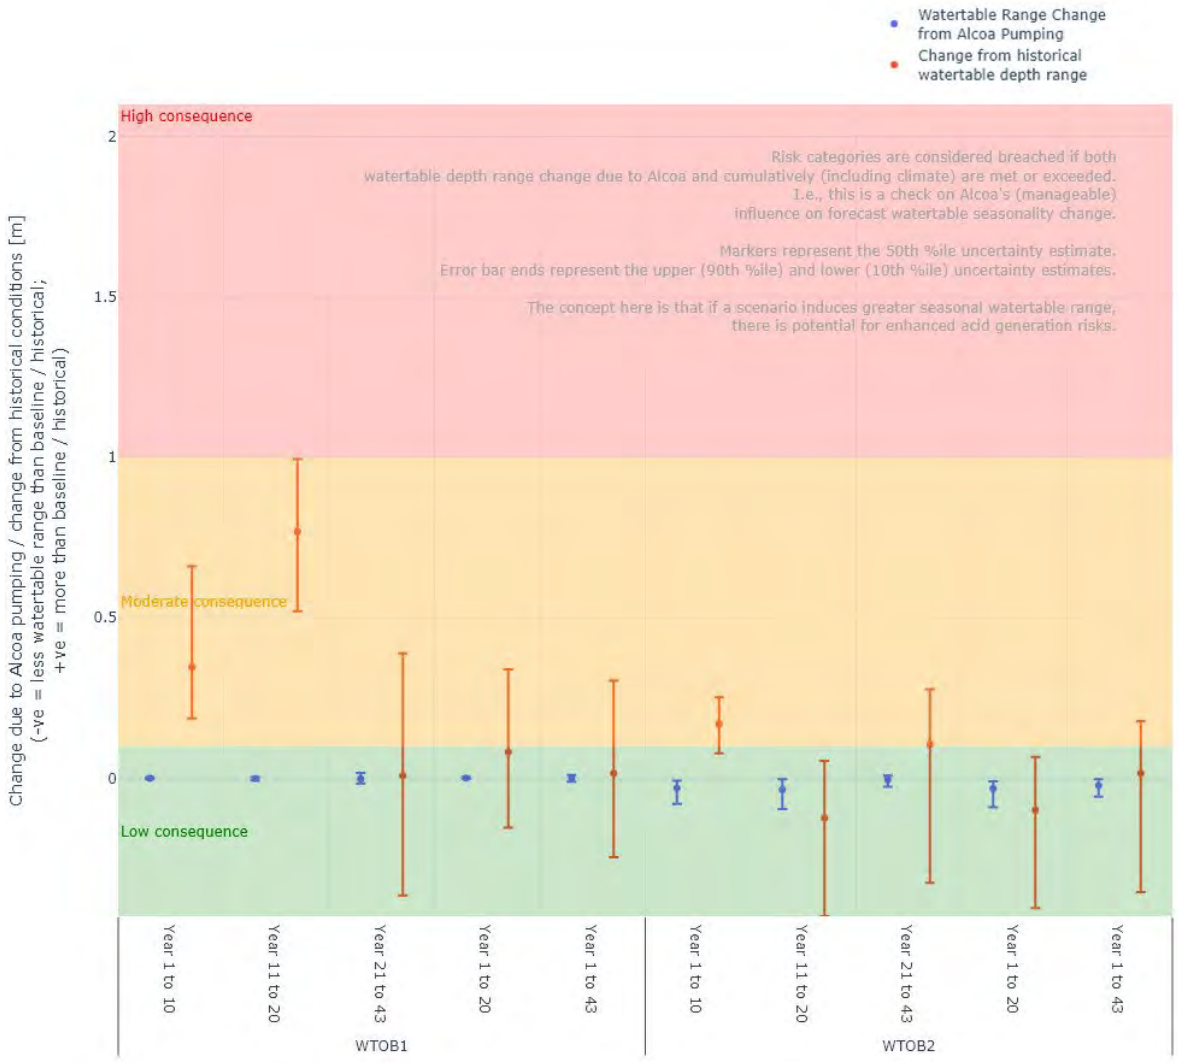

Figure 7-15 High Climate Change – Seasonal Variability of the ASA Watertable (WTOB1 and WTOB2) Relative to the 2010-2023 Historical Period

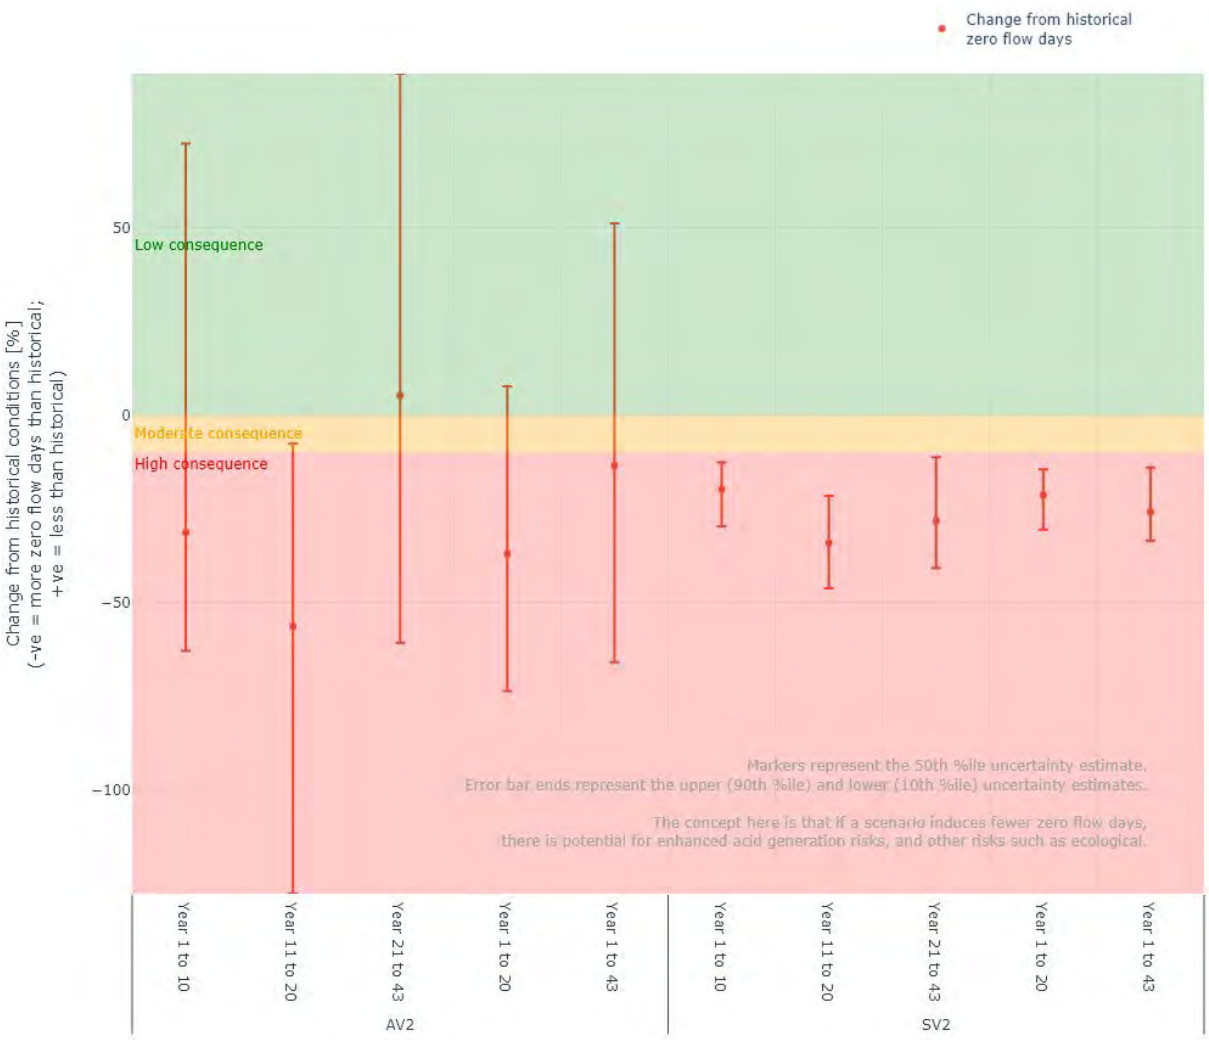

Figure 7-16 High Climate Change – Percent Change in Annual Zero-flow Days Relative to the 2010-2023 Historical Period

7.3.4 Reduction in Surface Water Flows

As presented in **Table 7-6**, the absolute flow rate difference as a percentage against flow from the baseline period was used to inform the risk of modifying catchment inflows to the Anglesea River Estuary from Marshy Creek and Salt Creek; specifically, a moderate or higher consequence is identified when:

- The mean annual absolute flow rate difference measured at AV2 and SV2 against the baseline period is greater than greater than 5 percent as a result of the pumping (in isolation from climate and other groundwater users); and/or
- The mean annual absolute flow rate measured at AV2 and SV2 against the historical period (2010 – 2023) has a difference greater than 5 percent as a result of the “cumulative” pumping and climatic factors.

The above is shown in **Figure 7-17** (medium climate) and **Figure 7-19** (high climate change), as per below:

- The mean annual absolute flow rate difference measured at AV2 and SV2 as a percentage are shown to the right.
- Blue markers show the change due to Alcoa pumping, as measured against the "no Alcoa pumping" case.
- Red markers show the cumulative range change, due to all factors including pumping, climate, and post-mining recovery. These are measured as change from the historical 2010-2023 period.

7.3.4.1 Median Climate Change

The results indicate that for the Alcoa pumping only scenario:

- Forecast annual flows at SV2 are expected to be generally higher than historical rates indicating groundwater extraction has inconsequential impact on flows within the Salt Creek catchment;
- Modelling suggests that Alcoa's pumping at AV2 may contribute only a minor (<5 percent) portion of flow reduction over the historical 2010-2023 period.

For the cumulative impact scenario:

- There is a large degree of uncertainty at both AV2 and SV2 in modelled estimates indicating climatic factors and variability control flow behaviour.
- Modelling generally suggests that flows will be higher at SV2 when compared to the historical period, while AV2 is modelled to be generally less than that over the historical 2010-2023 period by up to 50 percent.

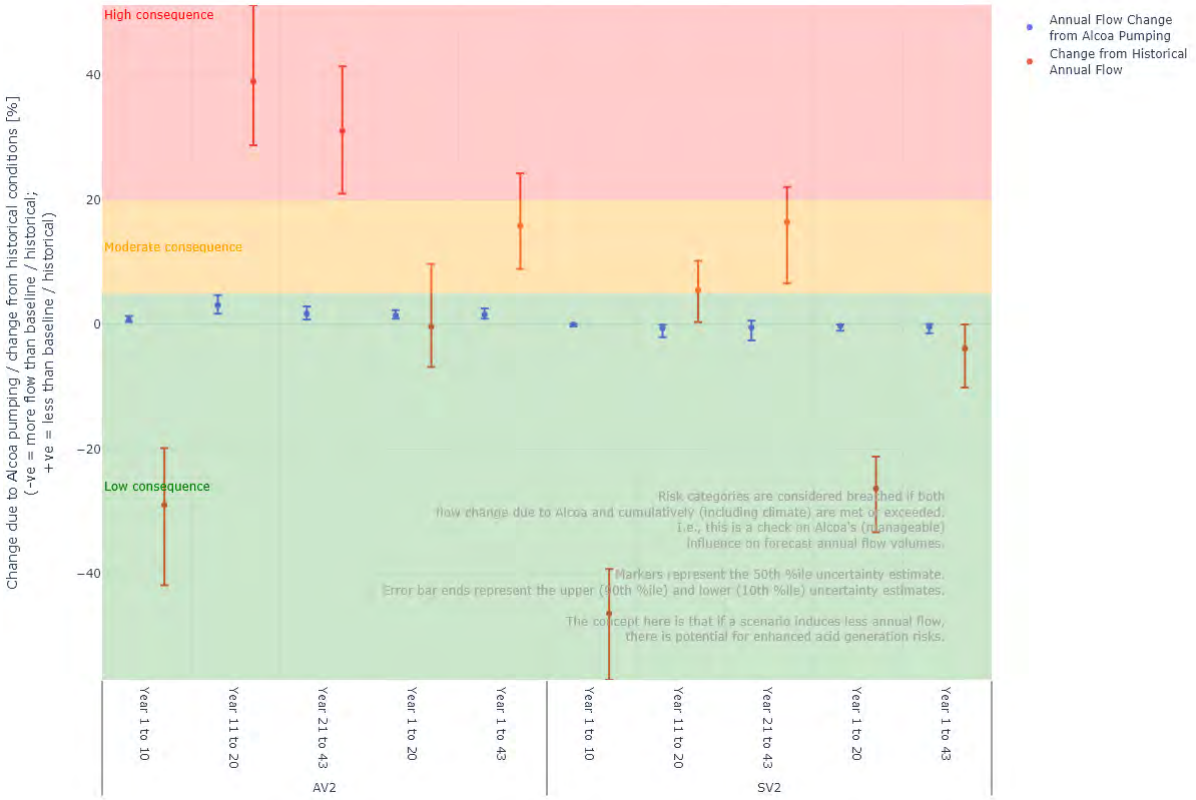

Figure 7-17 Median Climate Scenario – Salt Creek (SV2) and Anglesea River (AV2) Modelled Seasonal Flow Range Acid Generation Risk Metrics and Consequence Thresholds

Figure 7-18 Forecast Annual Flow Timeseries for SV2 and AV2

7.3.4.2 High Climate Change

The results indicate that for the Alcoa pumping only scenario:

- Forecast annual flow flows at SV2 are expected to be generally higher than historical rates, indicating groundwater extraction has inconsequential impact on flows within the salt creek catchment;
- Modelling suggests that Alcoa's pumping at AV2 may contribute minor consequence flow, except during years 11-20, when consequence on these terms may extend into the moderate range.

For the cumulative impact scenario:

- There is a large degree of uncertainty in modelled estimates at both AV2 and SV2, indicating climatic factors and variability control flow behaviour; however, under this climate regime (19 percent further decline in average annual rainfall), modelling suggests that both AV2 and SV2 flows will be significantly lower compared to the historical period.

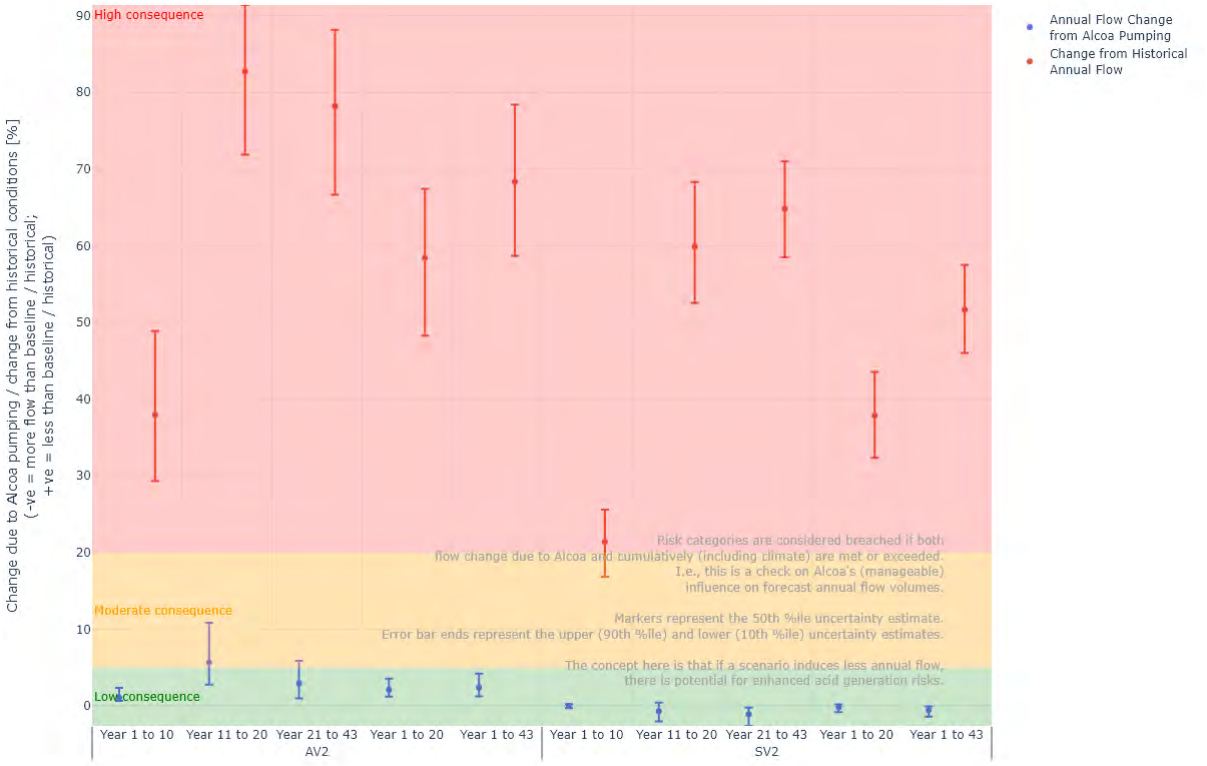

Figure 7-19 High Climate Scenario – Salt Creek (SV2) and Anglesea River (AV2) Modelled Seasonal Flow Range Acid Generation Risk Metrics and Consequence Thresholds

7.3.5 Pit Water Migration

As presented in **Table 7-6**, migration of pit water beyond the specified mine lease area into surrounding aquifers has been assessed. This was achieved using Scenario 1 (medium climate) from **Table 7-5** and assuming base realisation and a rapid pit fill scenario, i.e., the mine void fills within 12 months. By assuming such a rapid fill, this provided the greatest outward hydraulic gradient from which the pit water can migrate into the unsaturated material surrounding the mine.

The results (refer **Figure 7-20**) show that despite the rapid one-year fast fill scenario modelled, 98 percent of the model realisations (147 of 150) indicate that all particles migrating from the boundary of the mine void into the surrounding formation remain within the specified mine lease boundary within the simulation period (to 2066). All water particles are also simulated to discharge back into the mine void, confirming it acts as a groundwater sink for aquifers that intersect the mine in the long term. This is common in Australian post mine closures, as evaporation from the mine void generally exceeds the rate of discharge into it from both surface and groundwater.

Of the three model realisations that represent groundwater migration from edge of the water body across the Alcoa lease boundary (refer **Figure 7-21**), within these three realisations, it is only predicted to occur in 35 particles. That means that of the 300,000 particles simulated across 150 model realisations, totalling more than 45 million particles, only 35 particles indicate a level of cross lease migration risk. Furthermore, at the end of the model simulation (after 44 years), these particles are starting to turn back towards to mine water body.

The geochemical implication of mixing UEVF groundwater with mine void water is discussed in the hydrogeological risk assessment; refer **Section 8.1.4**.

Note: the intent is not to fill over 12 months (which was the conservative case modelled here), and therefore the risk of particle travel is actually much lower than shown in **Figure 7-20** and **Figure 7-21**.

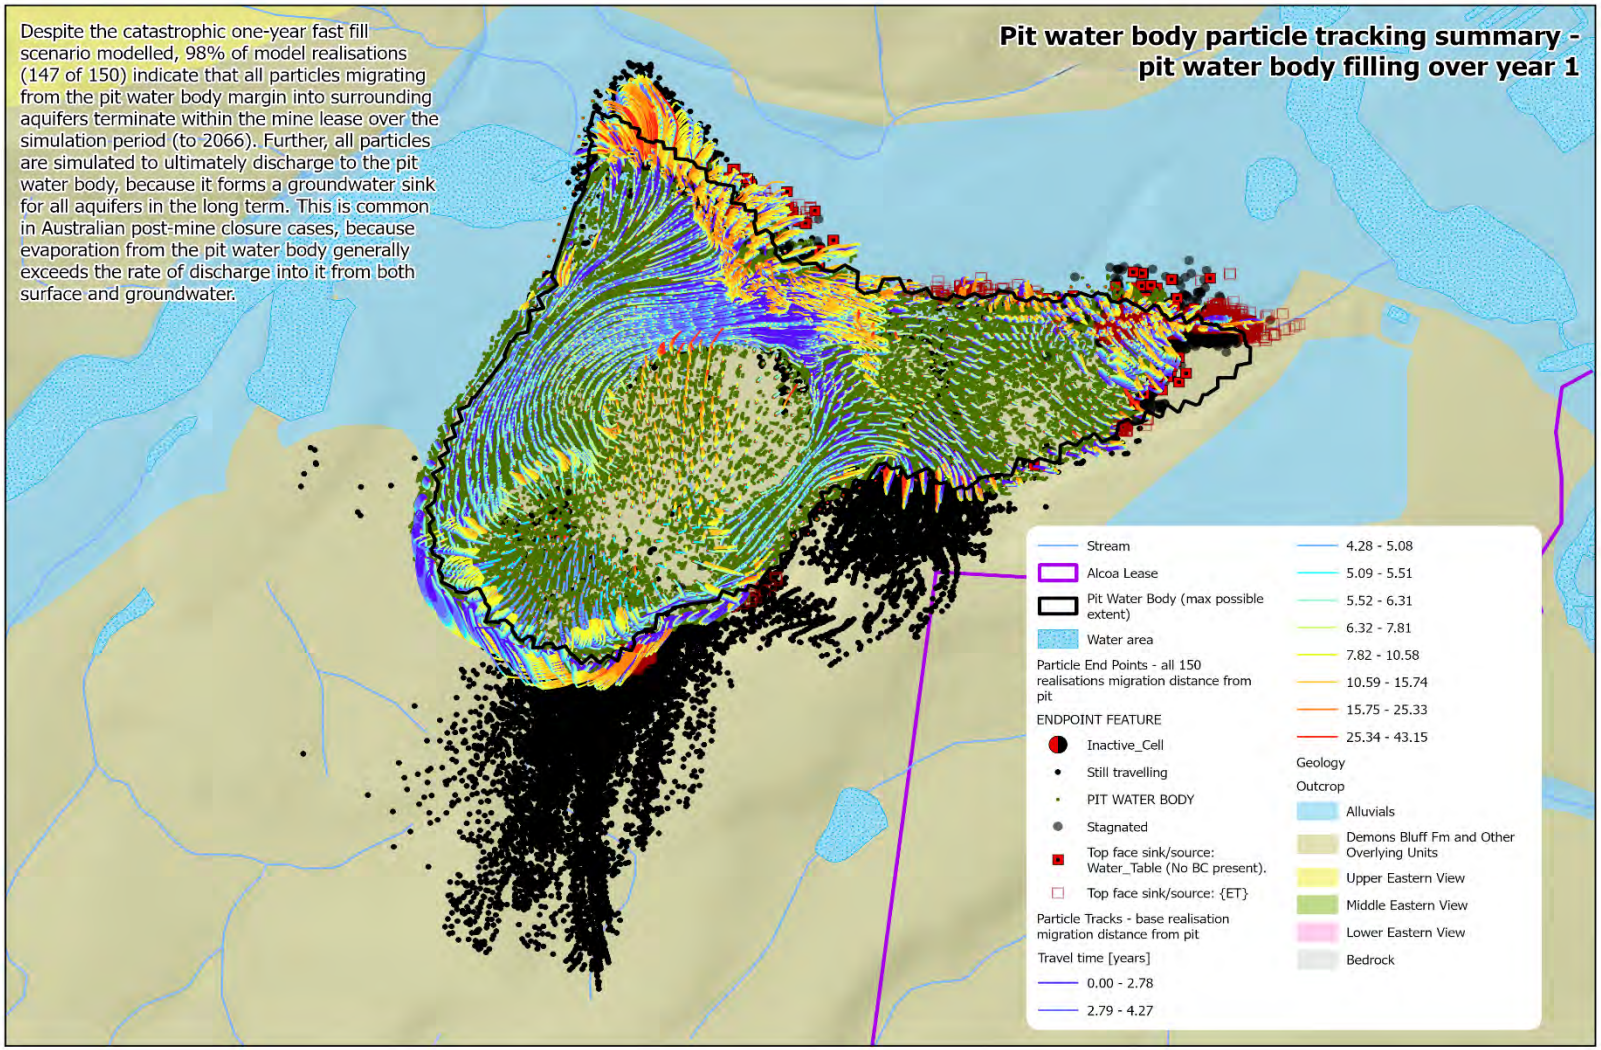

Figure 7-20 Mine Void Water Body Particle Tracking (1 year fill scenario)

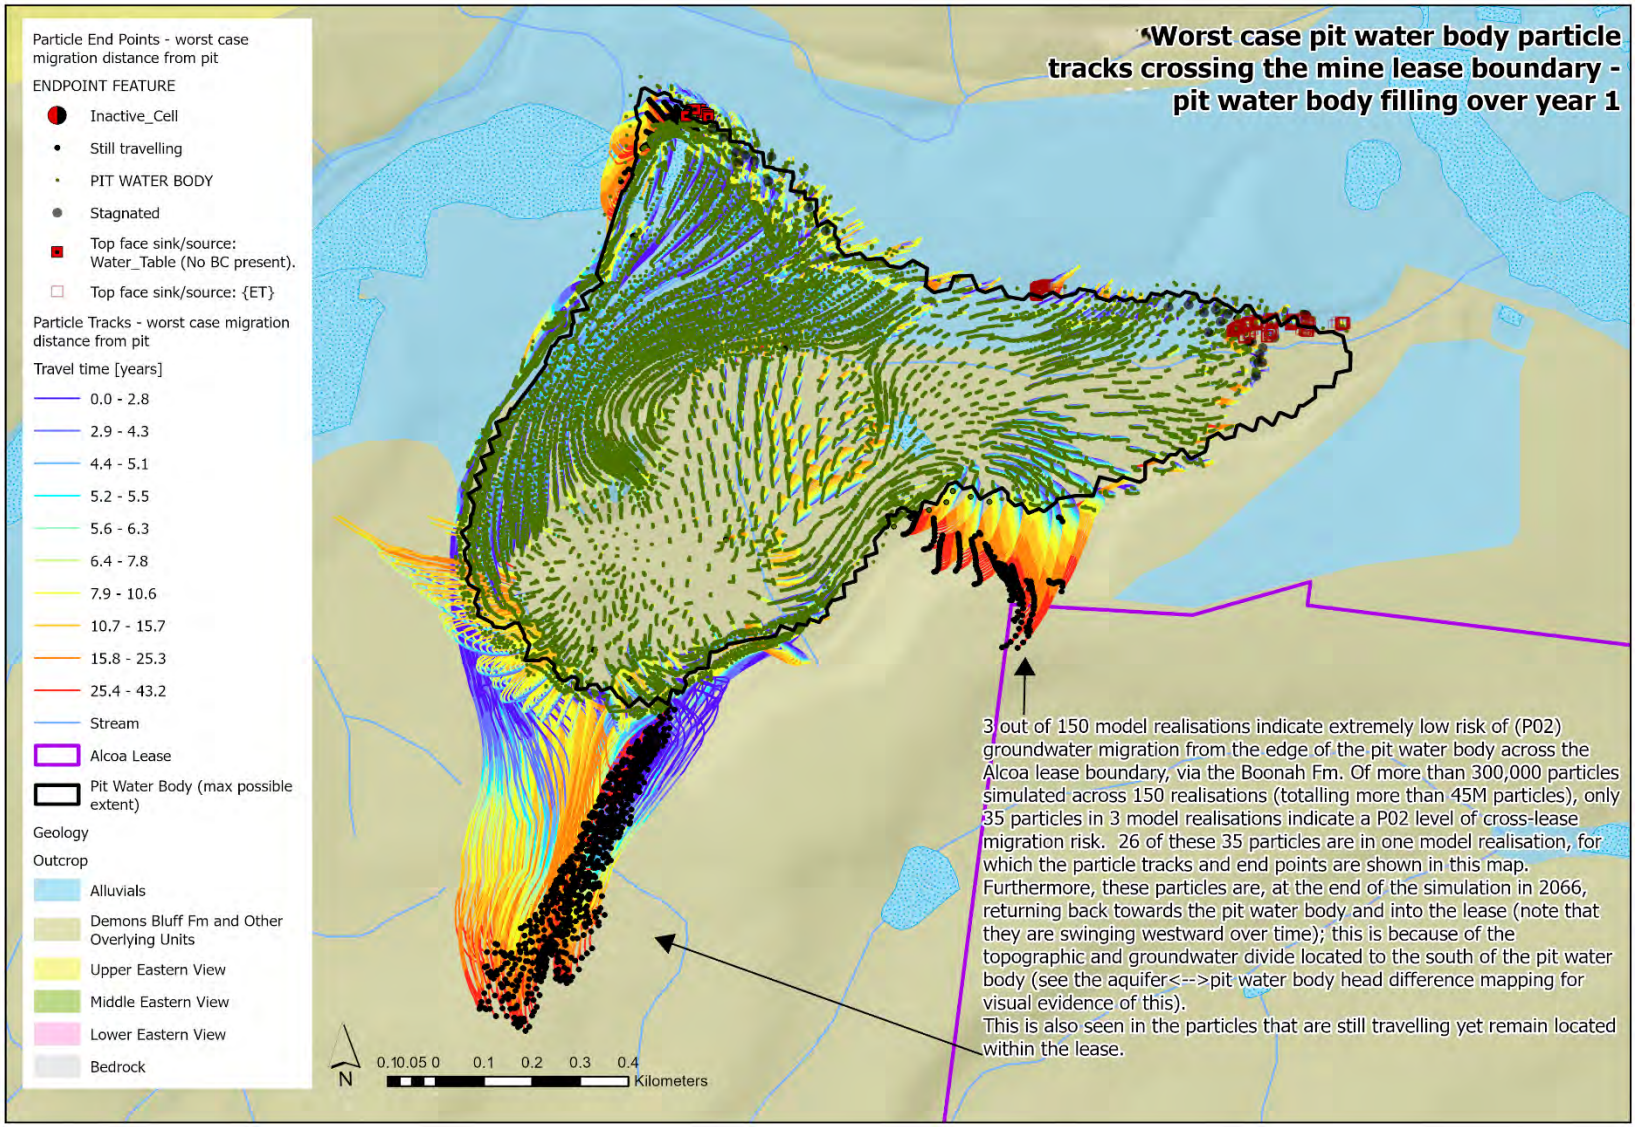

Figure 7-21 Mine Void Water Body Particle Tracking (Worst Case Scenario)

7.3.6 Modelled Water Budgets

A summary of the zone / model layer water budgets for key areas (**Figure 7-22**) has been provided in the sections below with all zone budgets outputs presented in **Appendix F4** to **Appendix F6**.

These results will help quantify the potential degree of leakage to and from the ASA, historically and also under various modelled scenarios as well as also determine where most of the water that enters the model, moves to.

These results were obtained by running 3 scenarios (refer below) defined within the Zone Budget feature within the groundwater model.

- **Scenario 1** = Angv7tr12u - Alcoa and Barwon Water Historical Use 1968 to 2022.
- **Scenario 2** = Angv7tr44u - Medium climate change; Barwon Water pumping 7GL/year for 5 years, then off for 5 years; No Alcoa pumping.
- **Scenario 3** =Angv7tr46u - Medium climate change; Barwon Water pumping 7GL/year for 5 years, then off for 5 years; Alcoa pumping from WB16 @ 1.5GL/year for 10 years. Discharge into the pit water body.

The zones that the water budgets were applicable to are presented in **Figure 7-22;** and listed below;

- Anglesea Estuary.
- Anglesea River ds Salt Creek.
- Anglesea River (lower-mid)
- Anglesea River (mid).
- Anglesea River (upper).
- Salt Creek (lower).
- Salt Creek (mid).
- Salt Creek (upper).

A summary of Alcoa potential influence on recharge to underlying formations is discussed in **Section 7.3.7**.

7.3.6.1 Scenario 1: Alcoa and Barwon Water Historical Use 1968 to 2022

Water balance flow components for all layers as a whole within the model domain is presented in **Figure 7-23**. To help quantify risk associated with the proposed application mean ASA leakage to the various underlying hydrogeological units (HGUs) for specified stream reaches is also presented, refer **Figure 7-24** (Anglesea River reaches) and **Figure 7-25** (Salt Creek stream reaches).

The results presented in **Figure 7-23** indicate the greatest losses of groundwater that enter the model are via groundwater evapotranspiration and aquifer storage (filling up aquifer pore spaces). An interesting observation between the two periods modelled (1968-2000) and (2001-2022) is in the later period, recharge entering the model has declined 46%. This corresponds to the notable reduction in average annual rainfall in the latter period, refer **Table 2-3.**

For historical modelled leakage from and to the ASA along the Anglesea River, the results, refer **Figure 7-24** and **Figure 7-26**, indicate that near the former mine and power station, leakage from the ASA to the underlying Demon Bluff Formation (DBF) occurs at a rate up to 0.014 ML/day/km^2. This increases to 0.048 ML/day/km^2 in the lower to mid sections of the Anglesea River where the intermediate sections of the UEVF underly the ASA. In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater.

The higher modelled leakage from the ASA in the mid part of the Anglesea River catchment is attributed to increase in vertical hydraulic conductivity for the underlying formation. Refer Figure 4-24, p.g 101 from GHD (2024), which shows that the vertical hydraulic conductivity of the UEVF Intermediate in this location is orders of magnitude greater than the demon bluff group located further down the catchment. Note that, if historical groundwater pumping were to significantly induce greater leakage over time from the ASA, potentially greater leakage rates would be seen in the zone Anglesea River lower-mid zone which is closer to the former Power Station, however this is not observed. Further, **Figure 7-35**, **Section 7.3.7** presents Alcoa's modelled potential influence on leakage to the ASA under Alcoa's proposed groundwater amendment and in this location, there is no distinguishable impact.

For historical modelled leakage from and to the ASA along Salt Creek, the results, refer **Figure 7-25**,and **Figure 7-27**, indicate in the lower part of Salt Creek, leakage from the ASA to the Boonah Formation is approximately 0.04 ML/day/km^2. This increases considerably immediately upgradient to 0.4 ML/day/km^2. In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater.

Conceptually, this increase in leakage is unlikely attributed significantly to historical pumping as the lower section of the UEVF in this location is relatively deep (>300m bgl) with thick sequences of confining geology separating the ASA and the Lower UEVF compared to other areas adjacent the pumping centre which have lower leakage rates. During early model run times (e.g. 1968 to 1975 and before groundwater extraction form the lower UEVF may have formed a cone of depression, modelled leakage or recharge in this zone is similar if not more than modelled leakage 2005 onwards, refer **Figure 7-25**. Simply put, higher historical leakage may have been due to greater surface water in the system available for recharge.

Finally, **Figure 7-28** presents a time series of modelled historical ASA leakage in the lower zone of Salt Creek. Evident on this graph, is an increase in leakage from the early 1980's. To further understand what may be causing this level of leakage, **Figure 2-4** which presents the progressive mining operations, shows between 1980 and 1985 the northwest corner of the mine and closest to the original part of Salt Creek were progressively mined. This may have provided a higher degree of potential connectivity between the ASA and the mine void in this location. However, its also important to note that in this location, ASA monitoring bores WTOB1 and WTOB2 show no trend in watertable elevation since monitoring began in 2009.

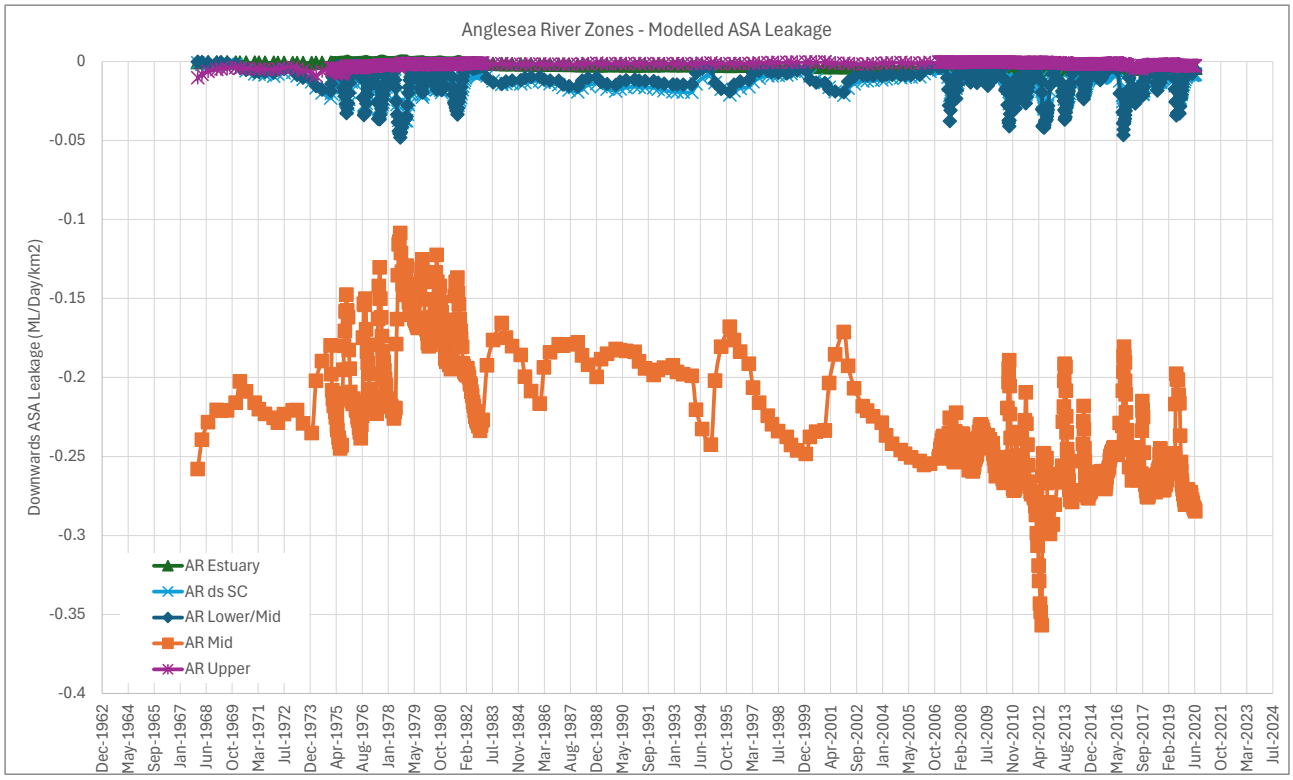

Figure 7-26 Modelled Historical ASA Leakage to Underlying Units Along the Anglesea River

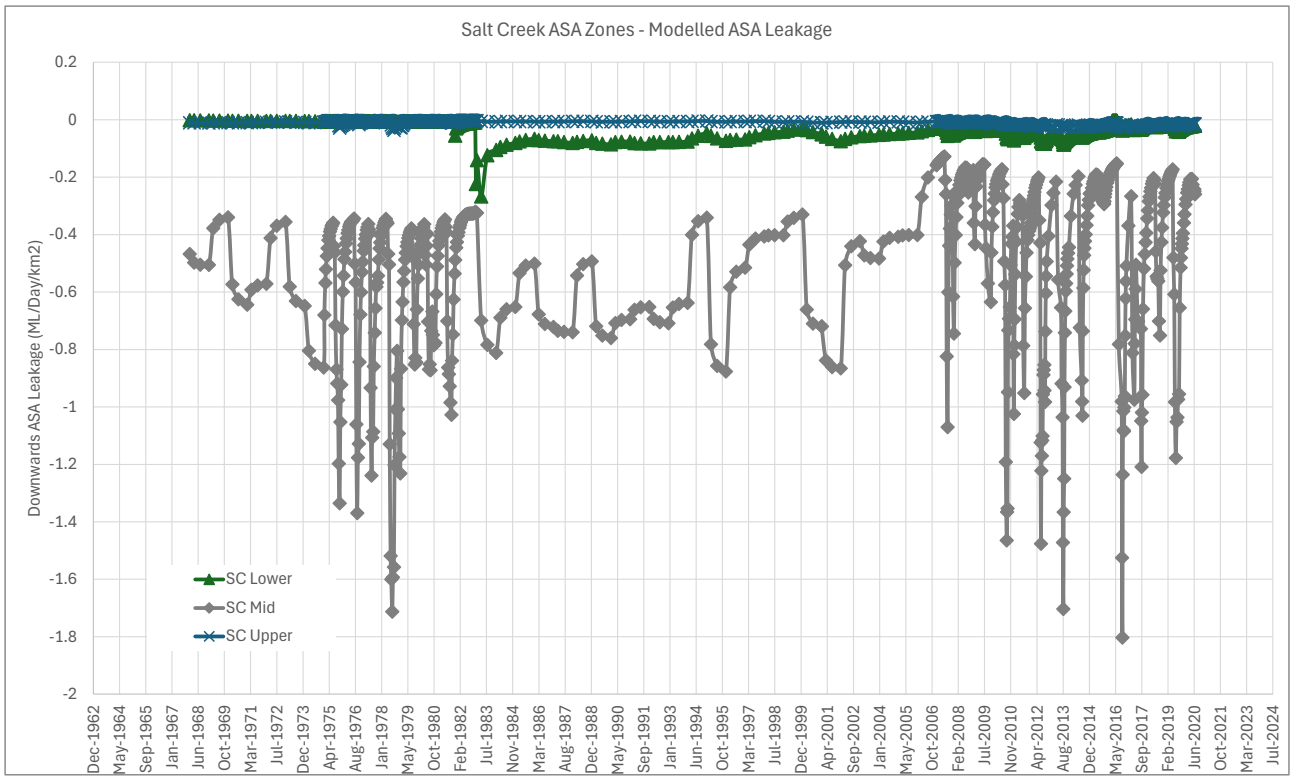

Figure 7-27 Modelled Historical ASA Leakage to Underlying Units Along Salt Creek

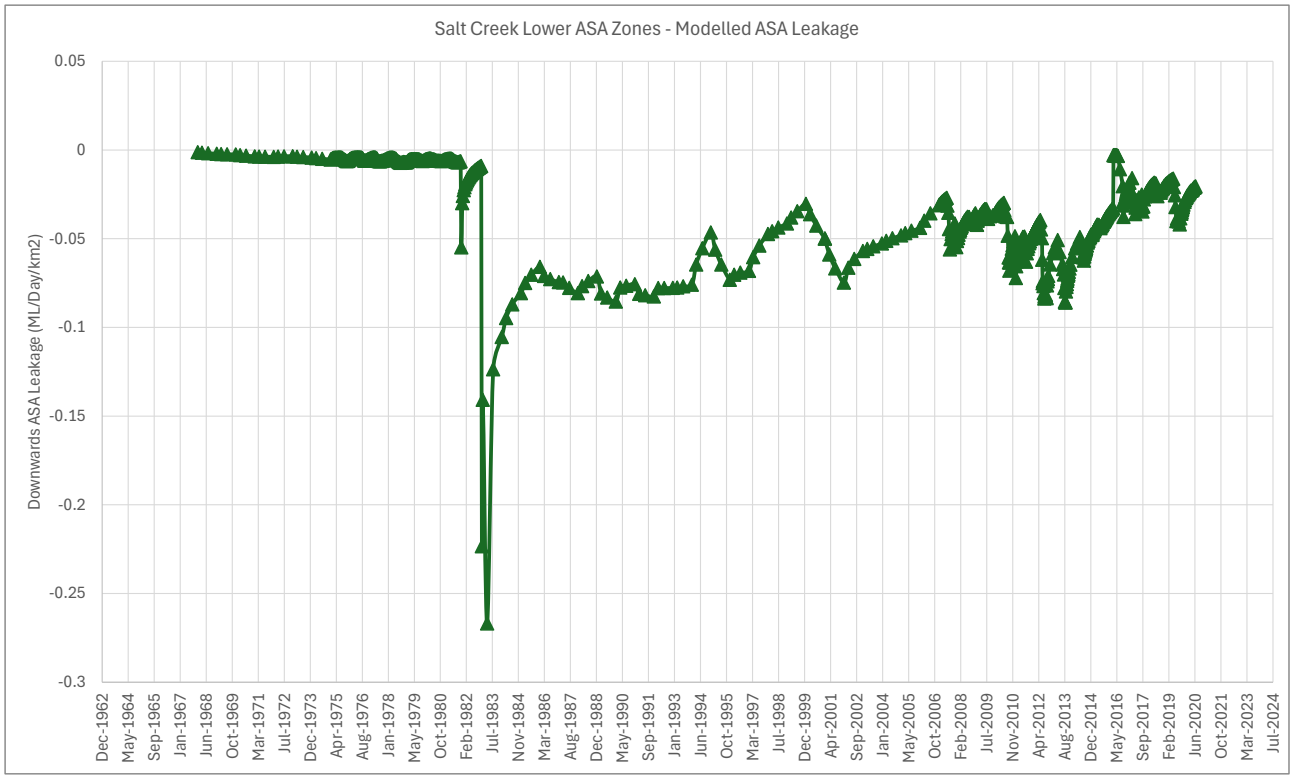

Figure 7-28 Modelled Historical ASA Leakage in the Lower Zone of Salt Creek

7.3.6.2 Scenario 2: Medium climate change; Barwon Water pumping 7GL/year for 5 years, then off for 5 years; No Alcoa pumping.

Water balance flow components for all layers as a whole within the model domain is presented in **Figure 7-29**. To help quantify risk associated with the proposed application mean ASA leakage to the various underlying hydrogeological units (HGUs) for specified stream reaches is also presented, refer **Figure 7-30** (Anglesea River reaches) and **Figure 7-31** (Salt Creek stream reaches).

As with modelled historical water balance outputs (refer **Section 7.3.6.1**), the results presented in **Figure 7-29** indicate the greatest losses of groundwater that enter the model are via groundwater evapotranspiration and aquifer storage, albeit these fluxes are slightly lower than those historically modelled. Mean ASA leakage per km^2 to the underlying geology is presented in **Figure 7-24** (Anglesea River) and **Figure 7-25** (Salt Creek).

For modelled leakage from and to the ASA along the Anglesea River, the results indicate that near the former mine and power station, leakage from the ASA to the underlying Demon Bluff Formation (DBF) occurs at a rate up to 0.014 ML/day/km^2 with the highest leakage to occur in the early time (2023-2033) before reducing to 0.005 ML/day/km^2 from2033 – 2066. This increases to up to 0.07 ML/day/km^2 in the lower to mid sections of the Anglesea River where the intermediate sections of the UEVF underly the ASA. In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater, however this net gain has reduced from 0.4 to 0.08 ML/day/km^2 when compared to 1968 to 2022.

For leakage from and to the ASA along Salt Creek, the results indicate in the lower part of Salt Creek, leakage from the ASA to the Boonah Formation is approximately 0.035 ML/day/km^2. This increases immediately upgradient up to 0.38 ML/day/km^2 which is similar to modelled historical leakage from 1968 to 2022 (Scenario 1). In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater, similar to modelled historical leakage from 1968 to 2022 (Scenario 1).

Appendix F5 presents all timeseries ASA leakage plots along the various zones.

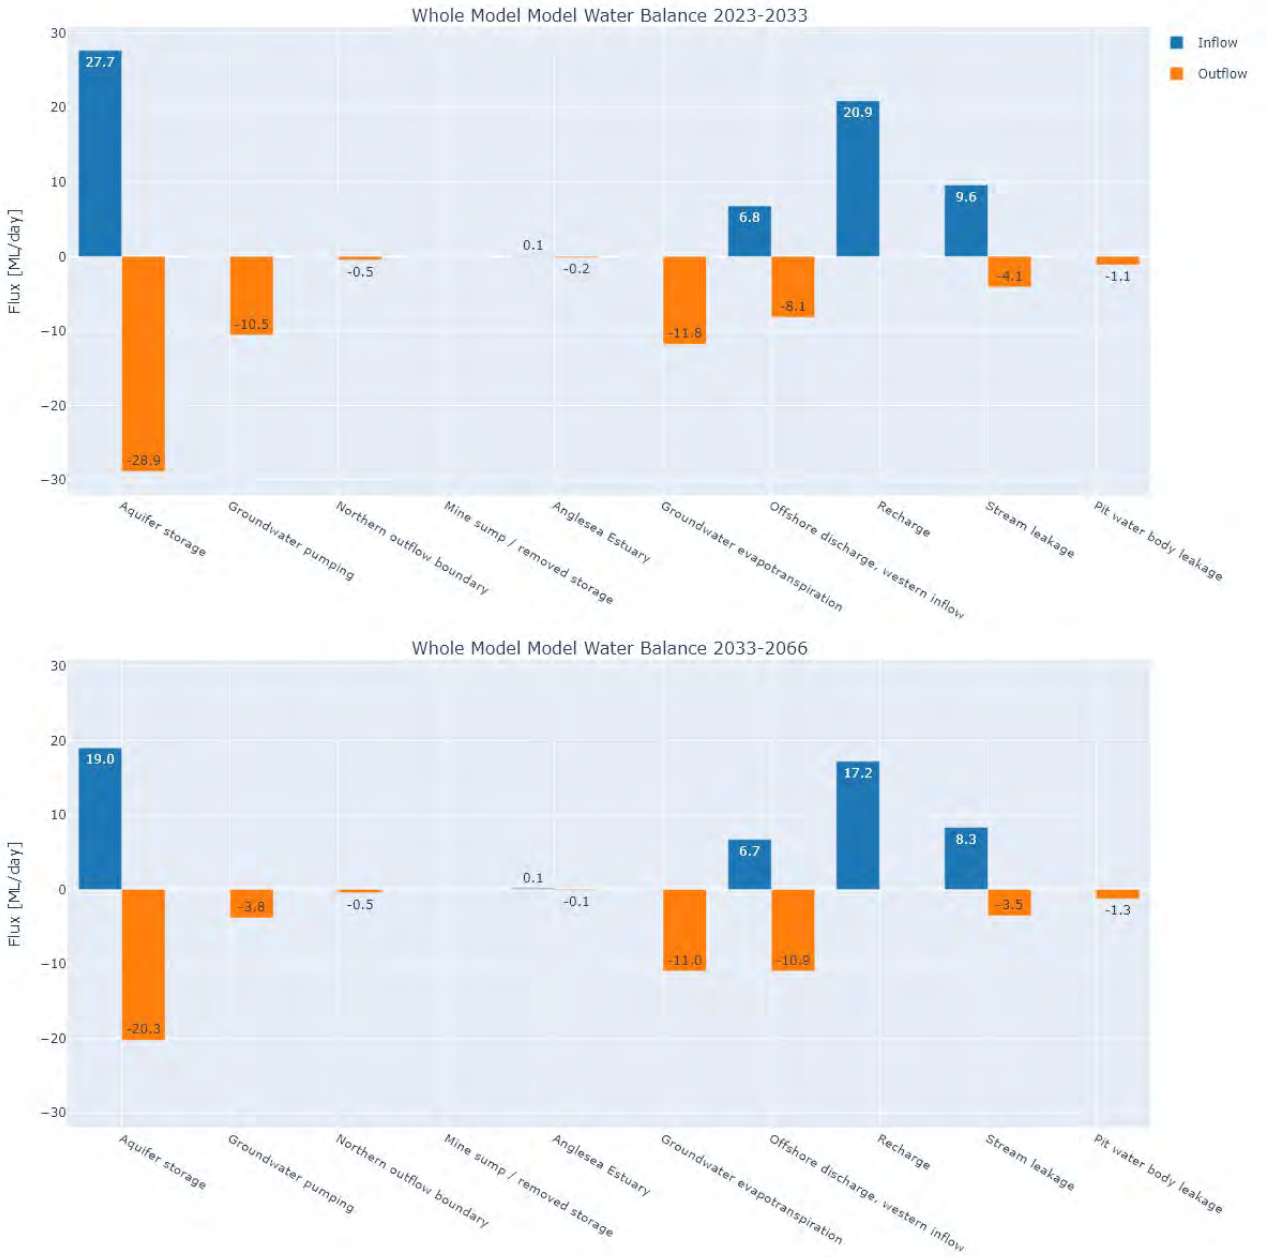

Figure 7-29 Scenario 2: Water balance flow components for all layers (Anglesea and Jan Juc syncline)

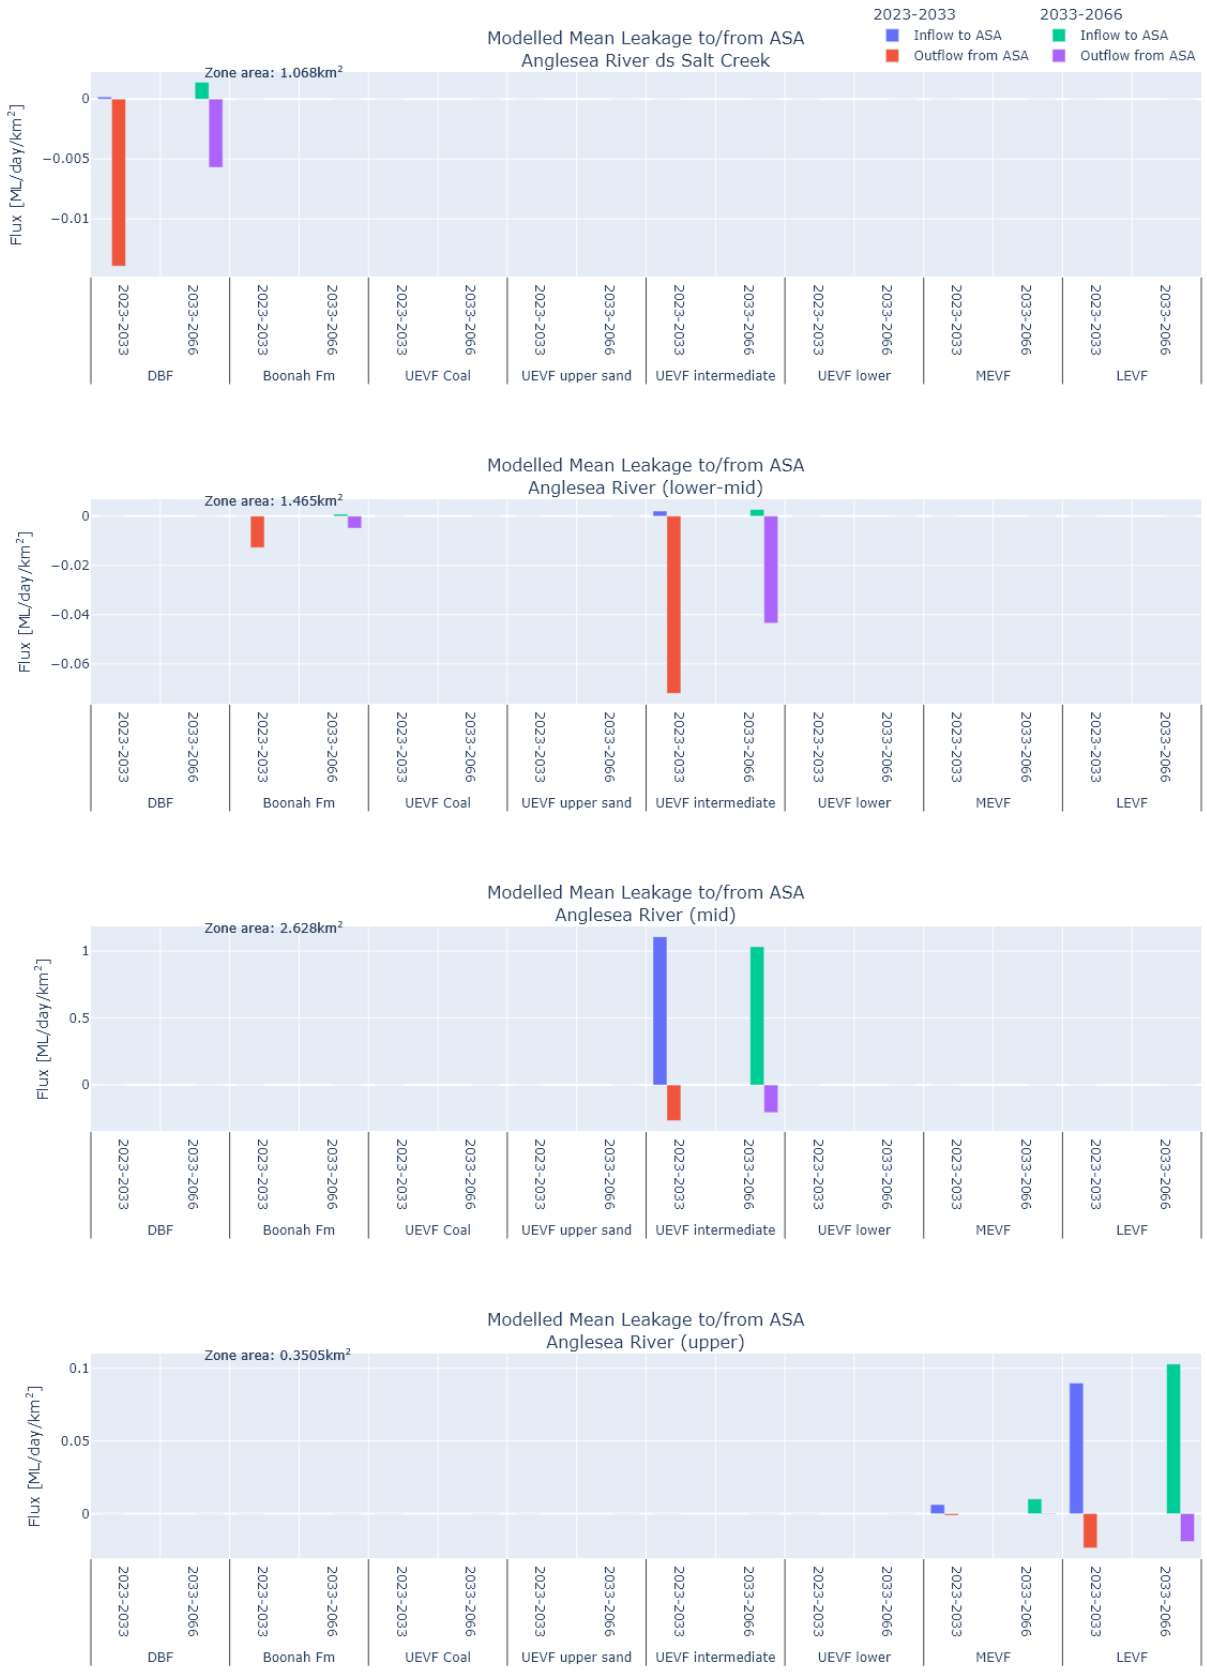

Figure 7-30 Mean ASA leakage to the various underlying aquifers along the Anglesea River

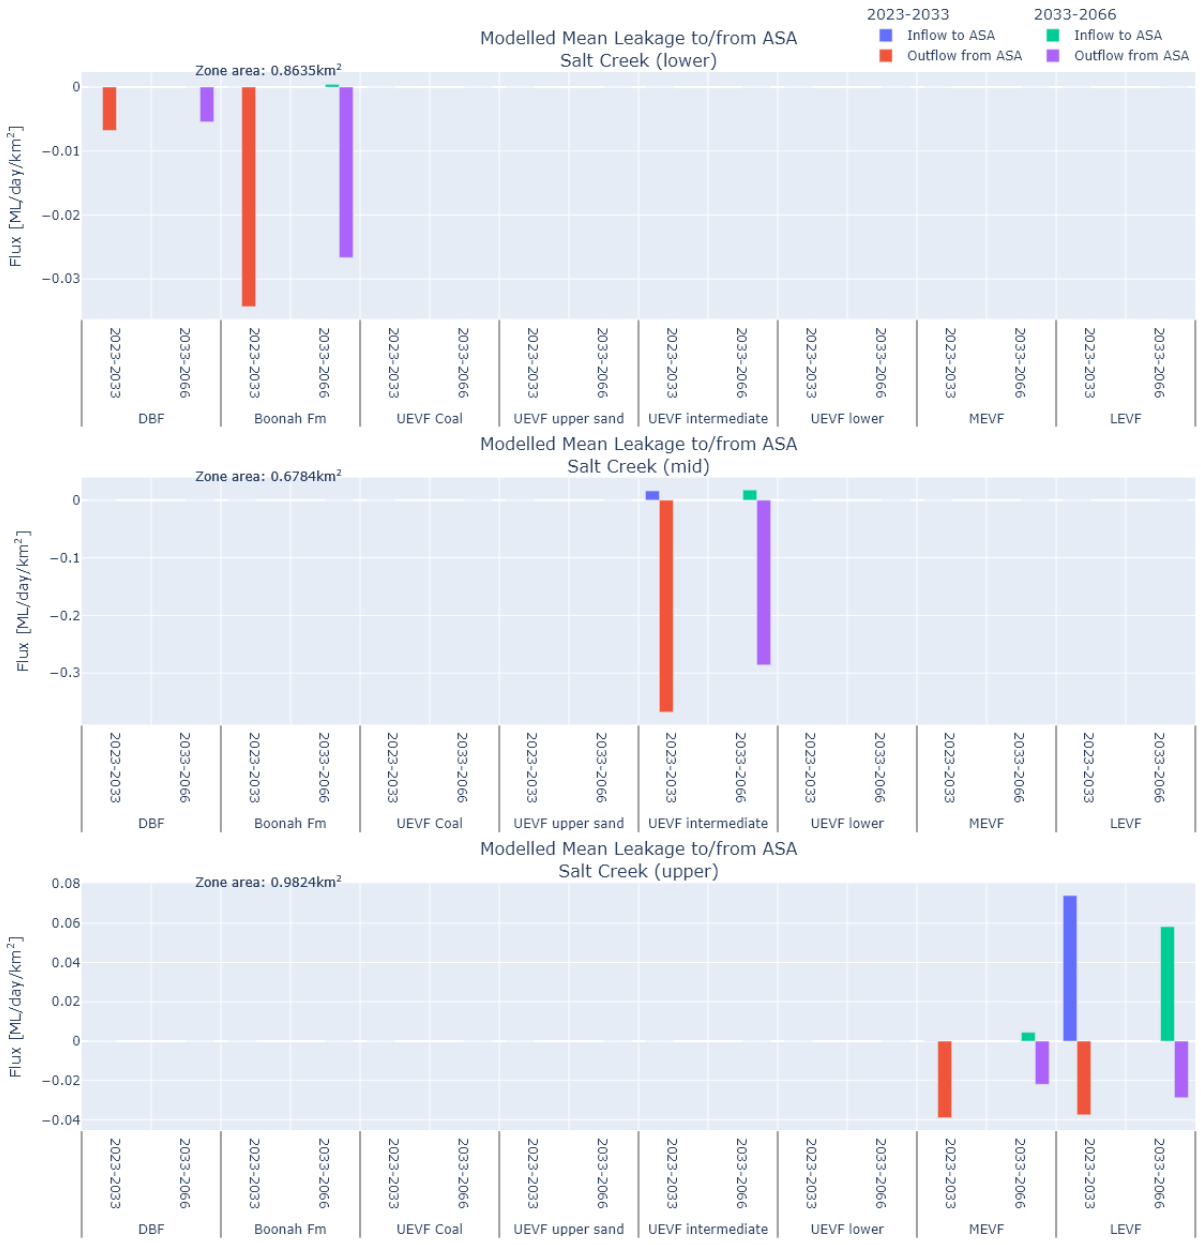

Figure 7-31 Mean ASA leakage to the various underlying aquifers along Salt Creek

7.3.6.3 Scenario 3: Medium climate change; Barwon Water pumping 7GL/year for 5 years, then off for 5 years; Alcoa pumping from WB16 @ 1.5GL/year for 10 years. Discharge into the pit water body.

Water balance flow components for all layers as a whole within the model domain is presented in **Figure 7-32**. To help quantify risk associated with the proposed application mean ASA leakage to the various underlying hydrogeological units (HGUs) for specified stream reaches is also presented, refer **Figure 7-33** (Anglesea River reaches) and **Figure 7-34** (Salt Creek stream reaches).

As with modelled historical water balance outputs (refer **Section 7.3.6.1**), the results presented in **Figure 7-32** indicate the greatest losses of groundwater that enter the model are via groundwater evapotranspiration and aquifer storage. Interestingly, stream leakage between this scenario and scenario 2, predict the same amount of stream leakage. Mean ASA leakage per km^2 to the underlying geology is presented in **Figure 7-32** (Anglesea River) and **Figure 7-34** (Salt Creek).

For modelled leakage from and to the ASA along the Anglesea River, the results indicate that near the former mine and power station, leakage from the ASA to the underlying Demon Bluff Formation (DBF) occurs at a rate up to 0.014 ML/day/km^2 with the highest leakage to occur in the early time (2023-2033) before reducing to 0.006 ML/day/km^2 from2033 – 2066. This increases to up to 0.08 ML/day/km^2 in the lower to mid sections of the Anglesea River where the intermediate sections of the UEVF underly the ASA. In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater, however this net gain has reduced from 1.5 to 1 ML/day/km^2 in the mid part of the catchment and 0.35 to 0.07 ML/day/km^2 in the upper part of the catchment when compared to 1968 to 2022.

For modelled leakage from and to the ASA along Salt Creek, the results indicate in the lower part of Salt Creek, leakage from the ASA to the Boonah Formation is approximately 0.035 ML/day/km^2. This remains relatively unchanged from Scenario 2. This leakage increases immediately upgradient up to 0.38 ML/day/km^2 which is similar to the leakage modelled in Scenario 2. In the mid and upper reaches of the catchment, the ASA has a net gain of groundwater, similar to modelled leakage in Scenario 2.

Appendix F5 presents all timeseries ASA leakage plots along the various zones.

Note: **Section 7.3.7** analyses the difference between Scenario 2 and Scenario 3. This is modelled Alcoa potential influence on leakage from the ASA.

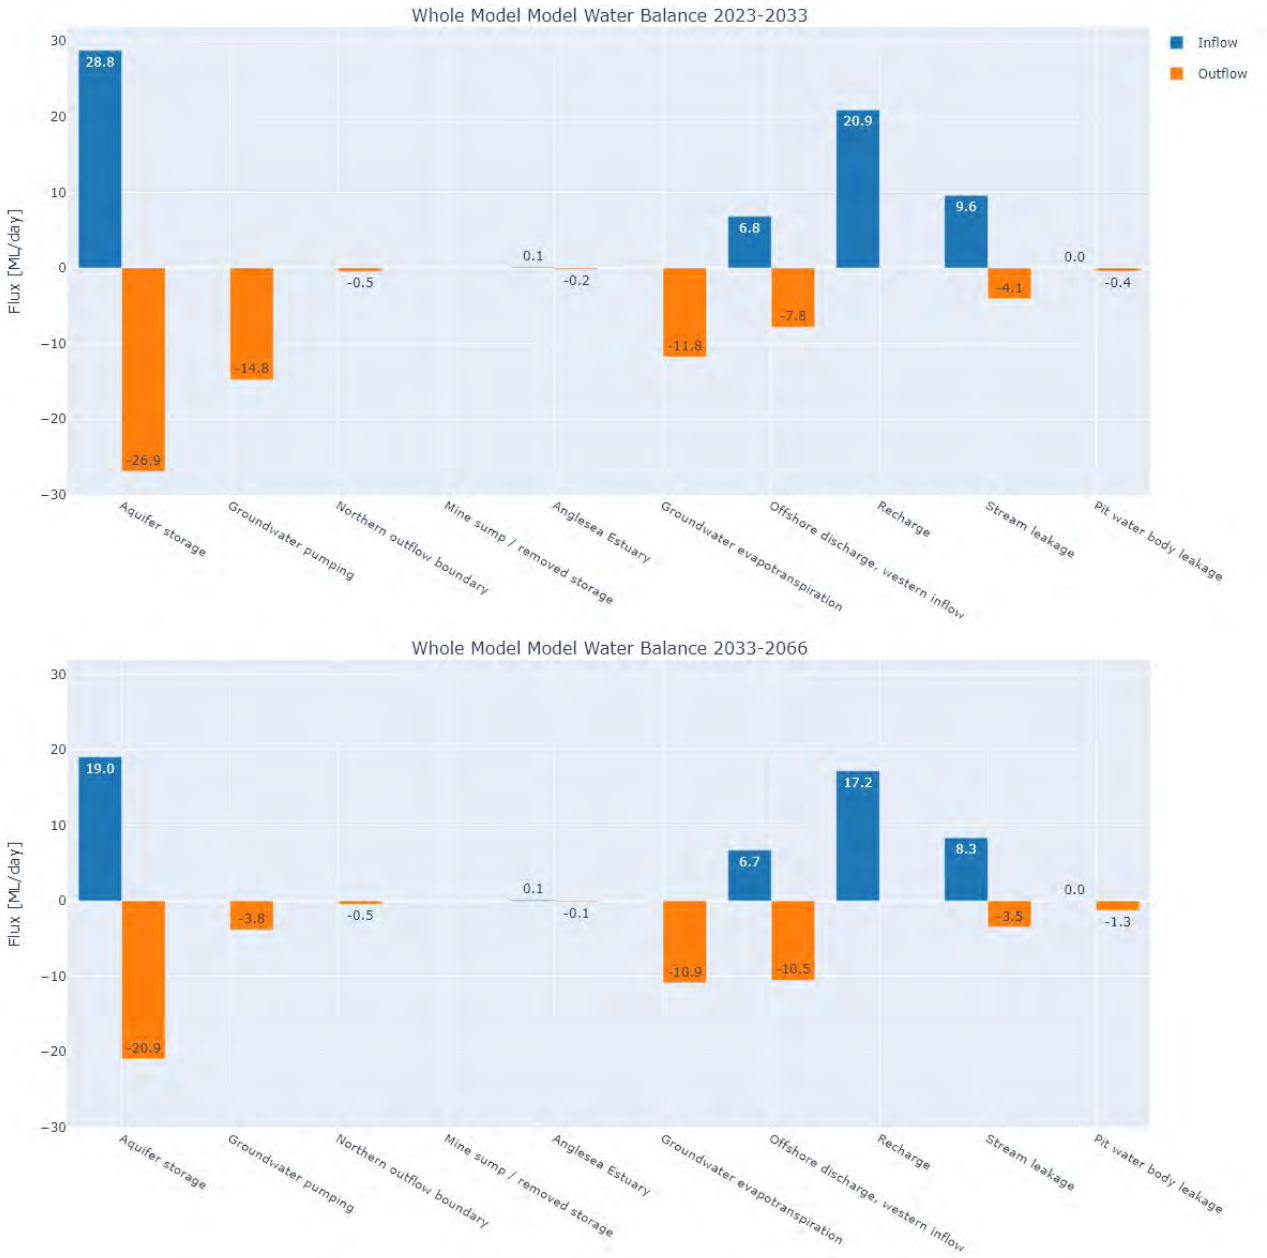

Figure 7-32 Scenario 3: Water balance flow components for all layers (Anglesea and Jan Juc syncline)

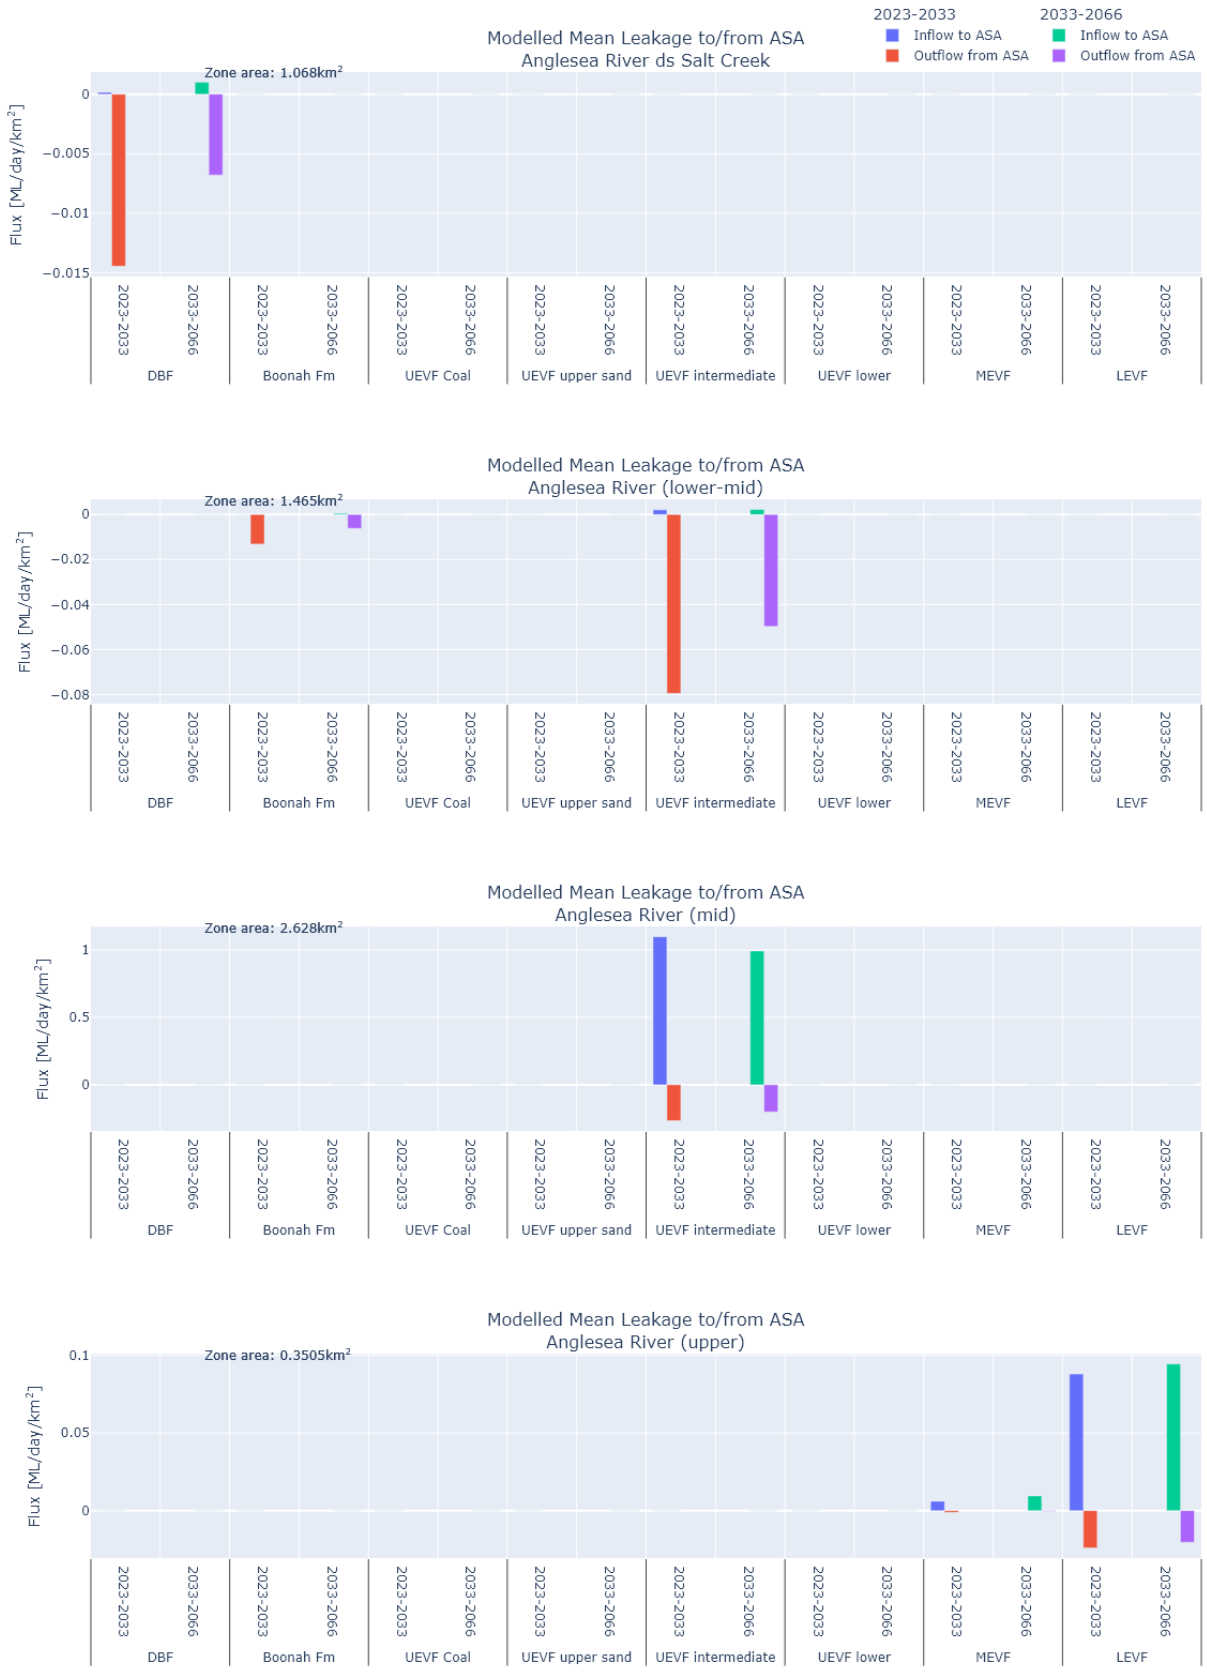

Figure 7-33 Mean ASA leakage to the various underlying aquifers along the Anglesea River

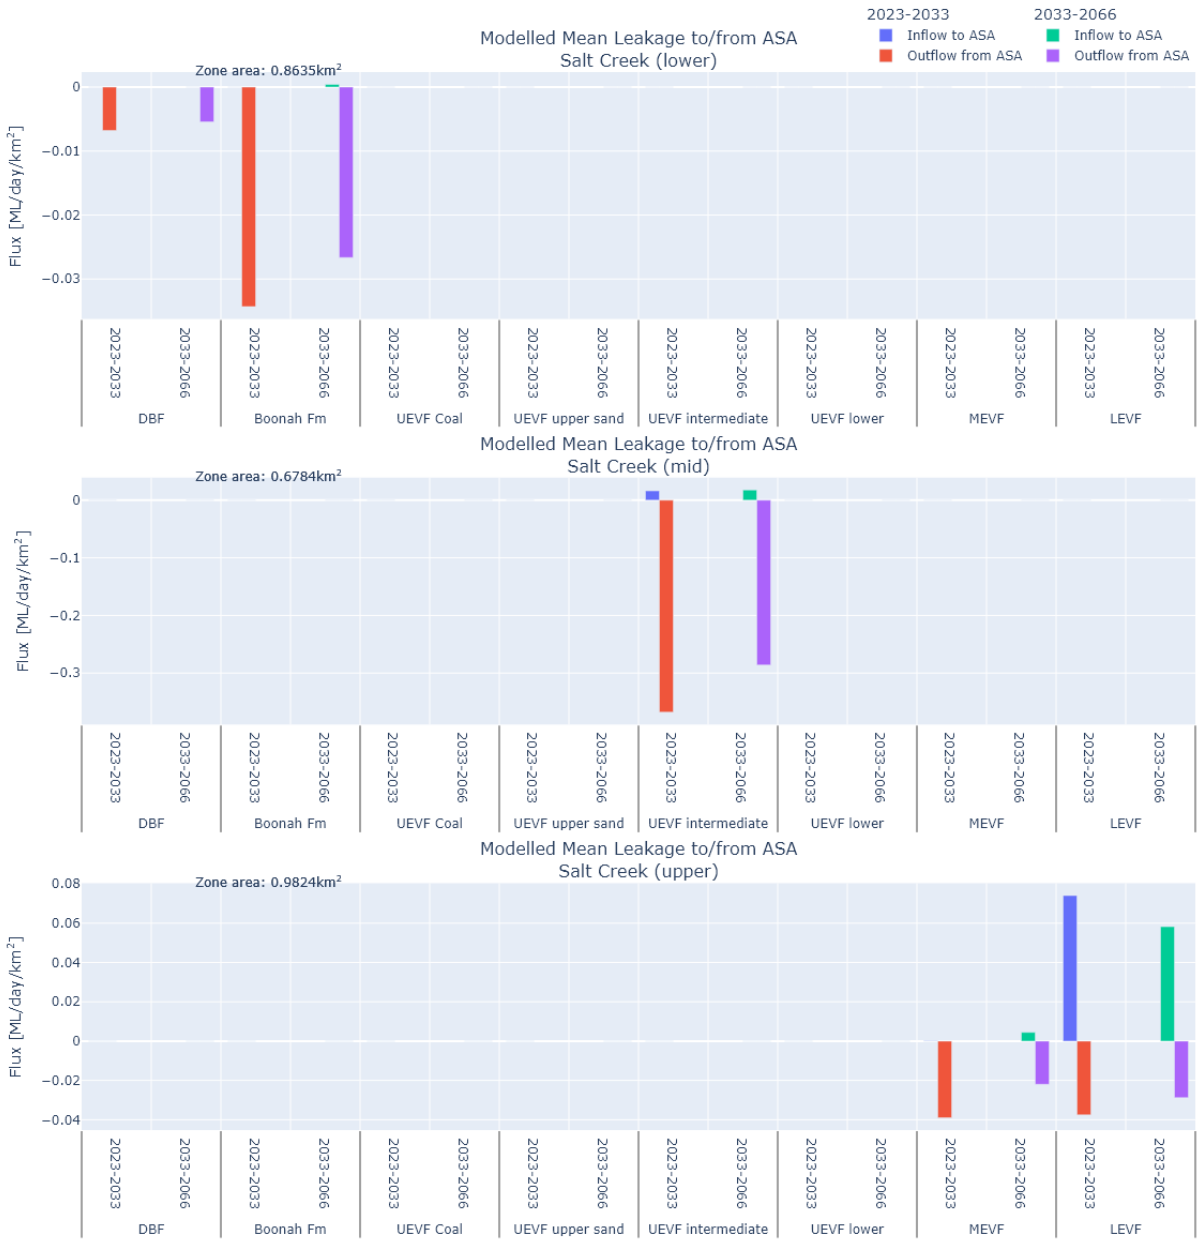

Figure 7-34 Mean ASA leakage to the various underlying aquifers along Salt Creek

7.3.7 Alcoa Potential Influence on Recharge

To analyse the impact that Alcoa's potential groundwater entitlement may have on leakage rates from the ASA to underlying formations, the difference between two forward looking scenarios (Angv7tr44u [scenario 2] and Angv7tr46u [Scenario 3]) were obtained. These are presented in **Figure 7-35**, and **Figure 7-37** to **Figure 7-41** (Anglesea River ASA zones) and **Figure 7-36** and **Figure 7-42** to **Figure 7-44** (Salt Creek ASA Zones)

For the ASA alignment within the Anglesea River catchment, the results indicate that the largest rate of leakage (potentially attributable to Alcoa pumping) from the ASA to the underlying formation occurs in the zone immediately upgradient of the former PowerStation, (refer **Figure 7-23)**. In this location median leakage between forecast Year 1 and Year 50 is 0.0008 ML/day/km^2 with a maximum leakage of 0.0068 ML/day/km^2, refer **Figure 7-35.**

To put this into context, a median increase in leakage of 0.0008 ML/day/km^2 as a result of Alcoa potential groundwater entitlement is approximately 0.30ML/yr (across the whole zone) or 0.0003% of Alcoa proposed annual entitlement (1500 ML/yr). In hydrogeological recharge terms since 1 m equals 1000 mm, 1 mm of rain is 1 litre per square metre and as the area of this zone is 1,464,576 m^2, 0.0008 ML/day/km^2 represents approximately 0.43 mm/yr (or approximately 0.9% of the modelled recharge rate), refer **Table 7-9**.

For the ASA alignment within the Salt Creek catchment, the results indicate that the largest rate of leakage (potentially attributable to Alcoa pumping) from the ASA to the UEVF Intermediate sediments occurs in the mid part of catchment. In this location (refer **Figure 7-23)** the median leakage between forecast Year 1 and Year 50 is 0.001 ML/day/km^2 with a maximum leakage of 0.04 ML/day/km^2. Refer **Figure 7-36.** Similar to the assessment above, as the area of this zone is 679,422 m^2, 0.003 ML/day/km^2 represents approximately 0.75 mm/yr (or approximately 1.25% of the modelled recharge rate), refer **Table 7-9**.

Table 7-9 Alcoa Modelled Recharge Impacts to the ASA

Parameter	Unit	ASA Mid Salt Creek	ASA Mid Anglesea River
Modelled Mean Leakage	ML/day/km2	0.0008	0.001
	L/day/km2	800	1000
	L/yr/km2	292000	365000
	mm/yr/km2	292000[1]	365000[1]
Area	km2	0.68	1.46
	m2	679422	1464576
Mean Modelled Recharge	mm/yr	50[2]	20[2]
Recharge Rate Equivalent	mm/yr	0.43	0.75
% of Calibrated Recharge Rate	%	0.86	1.25

[1]A rainfall of 1 mm supplies 0.001 m^3, or 1 litre of water to each square metre of the land.

8 Hydrogeological Risk Assessment

The risks presented in this section account for both the potential impacts resulting from Alcoa proposed UEVF groundwater use and for completeness, the cumulative impacts which may arise if the proposed Buk Entitlement of the LEVF is exercised in addition to Alcoa's proposed extraction. Whilst the operation and permitting of any LEVF extraction is beyond the control of Alcoa, it included as a reference scenario as required by Southern Rural Water.

In addition, it should be noted that risks presented within this assessment are without the mitigating factors that would be found within a Water Management and Monitoring Plan (refer **Section 10**). When these are implemented, this would only further reduced and potential risks associated with the application.

As discussed in **Section 7** (**Table 7-6**), risk is defined by consequence and likelihood. The consequence was determined by the modelled median prediction (P50) from the 150 unique realisations from the modelled scenario whilst the method presented in Peeters & Middlemis (2023[1]) determined the likelihood. The decision to adopt Peeters & Middlemis (2023) is because the Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems (DELWP 2015) provide no guidance on definition for likelihood (e.g., unlikely, possible, certain). This method also advances the best practice Australian Groundwater Modelling Guidelines ('AGMG'; Barnett et al., 2012) and have been adopted by the Independent Expert Scientific Committee on Coal Seam Gas and Large Coal Mining, IESC (2023). This approach will achieve this as the numerical model will produce 150 realisations (predictions) for each climate scenario. Of these 150 realisations, the P10 and P90 outputs will represent the bounds of probability (or likelihood).

Based on the Peeters & Middlemis (2023), the probability of an outcome is as follows:

- Less than 10th percentile indicates it is very likely the outcome is larger than this value.
- 10th–33rd indicates it is likely that the outcome is larger than this value.
- 33rd–67th indicate it is as likely as not that the outcome is larger or smaller than this value.
- 67th–90th indicates it is unlikely that the outcome is larger than this value.
- Greater than 90th percentile indicates it is very unlikely the outcome is larger than this value.

For example, if 100 model simulations were run, and 80 simulations lie within the 10 - 90 percent categories, then 20 simulations predicted outcomes outside the criteria range selected. In this way likelihood is based on a quantitative assessment of the available data produced by the model.

Within this GIA, and to err on the side of conservatism and commensurate with the historical data and calibration (history matching), the above probabilities have been further condensed as follows:

- Less than 10th percentile indicates the outcome is very likely larger than this value.
- **10th–90th percentile indicates the result is as likely as not that the outcome is larger or smaller than this value.**
- Greater than 90th percentile indicates it is very unlikely the is larger than this value.

As presented in **Section 7.3**, the results show error bars representing model uncertainty over the 10th to 90th percentile range. An example risk matrix is presented in **Table 8-1**.

Table 8-1 Risk Assessment Matrix

		Consequence		
		Minor	**Moderate**	**Significant**
Likelihood / Probability	**Very unlikely (n ≤ P10)**	Low	Low	High
	as likely as not (P10 > n < P90)	Low	Medium	High
	Very likely (n ≥ P90)	Medium	High	High

The above risk assessment process uses a similar framework outlined in Victorian Governments Preparation of Work Plans and Work Plan Variations, Guidelines for Mining Projects, December 2020 (version 1.3), referenced here after as ERR (2020). However, the major difference is the risk matrix presented in **Table 8-1** is more conservative based on **BOTH** the likelihood or probability of an impact happening when compared to the process shown in ERR (2020).

For example, **Table 8-2** presents the likelihood definitions within ERR (2020), **Table 8-3** (consequences), and **Table 8-4** overall risk. As a numerical model output is based on a quantitative series of probabilities (in this case the probability of a result occulting from 150 model realisations), it was determined that if the result fell outside of the top and bottom tenth percentile, the event was 'as likely as not' of occurring. This would capture the majority of the "unlikely" events presented in **Table 8-2.**

Table 8-2 Likelihood Definitions (adapted from ERR 2020)

Severity	**Description**	**Probability of event occurring**
Almost certain	The risk event is expected to occur in most circumstances.	90 – 100%
Likely	The risk event will probably occur in most circumstances	70 – 90%
Possible	The risk event might occur at some time	30 – 70%
Unlikely	The risk event could occur at some time	5 – 30%
Rare	Highly unlikely, but the risk event may occur in exceptional circumstances.	0 – 5%

Table 8-3 Consequence Definitions (adapted from ERR 2020)

	Consequences Level				
	Insignificant	**Minor**	**Moderate**	**Major**	**Critical**
Consequences for the environment	Impacts are barely recognised and/or quickly recovered from. No specific remediation required. **Example:** **Hazard event with minimal environmental impact and no noticeable effect beyond the immediate occurrence or expression of the hazard**	Hazard is perceived but has minor and typically temporary effects. Some remediation may be required. **Example:** **Minor contamination of natural waterway or wetland occurs, but water quality remains within applicable EPA or ANZECC guidelines for existing beneficial uses.** **Water extraction or diversion reduces surface water flows or groundwater available for environmental uses, but with no detectable effect on dependent species or ecosystems and carried out within terms of water licence.**	Hazard has moderate, noticeable impact, in terms of severity, duration and/ or frequency of occurrence. Moderate treatment or Remediation effort may be required. Hazard event would be the subject of limited community concern. **Example: Localised contamination of surface water/groundwater aquifer leading to disruption of beneficial for weeks to months.**	Hazard has major impact, in terms of severity, duration and/ or frequency of occurrence. Treatment or remediation effort is required. Some effects may be irreversible. Remediation of environmental contamination would require significant Private and public resources. Hazard event would be the subject of widespread community concern. **Example: Contamination of surface water/ groundwater aquifer leading to disruption of beneficial uses for up to one year**	Hazard has critical impact, in terms of severity and/ or duration. Treatment or remediation effort is required, although some effects may be irreversible. Remediation of environmental contamination would require significant Private and public resources. Hazard event would be the subject of widespread community outrage. **Example: Contamination of surface water/ groundwater aquifer leading to disruption of beneficial uses for more than year**

Table 8-4 Risk Matrix (adapted from ERR 2020)

		Consequence				
		Insignificant	Minor	Moderate	Major	Critical
Likelihood	Almost Certain	Medium	High	Very High	Very High	Very High
	Likely	Medium	Medium	High	Very High	Very High
	Possible	Low	Medium	Medium	High	Very High
	Unlikely	Low	Low	Medium	High	High
	Rare	Low	Low	Medium	Medium	High

8.1 Impact Assessment

Note: Due to significant model run time, and as presented in **Section 7.2.4** and **Table 7-5,** there is no singular model scenario whereby Alcoa proposed pumping activity was undertaken in isolation and as a single run. As such and to satisfy Section 40 of the Water Act 1989, from the scenarios modelled, the results presented in this application have isolated Alcoa's pumping impact from other cumulative impact contributors such as Barwon Waters Bulk Entitlement and climatic factors, also presented in this application.

This was achieved by developing a script that numerically subtracted outputs Scenario 2 (Barwon Water only pumping) from Scenario 3 (Alcoa + Barwon Water pumping). By using this approach, the modelled outputs are more conservative (thus satisfying Section 40 of the Water Act 1989) as this potentially results in larger Alcoa impacts, than if modelled as a single scenario. This is because it takes Alcoa pumping impact under conditions in which the aquifer is more stressed, as Barwon Water is also pumping in both scenarios.

8.1.1 Risks to Groundwater Dependant Ecosystems

As discussed above, risk is defined as consequence multiplied by likelihood (or probability) of exceedance (**Table 8-5**).

The consequence of an impact to GDEs in this GIA has been defined using the Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems (DELWP 2015). The consequence descriptors are below and presented in **Table 8-5**.

- **Minor Consequence**, where:
  - The modelled change in watertable depth (mean annual average drawdown) is caused by simulated pumping in isolation of all other effects across the mapped marshlands of the ASA (including locations WTOB1 or WTOB2) is less than 0.1m.
- **Moderate Consequence**, where:
  - The modelled change in watertable depth (mean annual average drawdown) is caused by simulated pumping in isolation of all other effects such as climate and other groundwater users across the mapped marshlands of the ASA (including locations WTOB1 or WTOB2) is greater than 0.1 m but less than 2m; and/or
  - The “cumulative” drawdown (mean annual average drawdown), accounting for the effects all groundwater pumping across the mapped marshlands of the ASA (including locations WTOB1 or WTOB2), is greater than 0.1 m but less than 2m.
- **Significant (High) Consequence**, where:
  - The modelled change in watertable depth (mean annual average drawdown) is caused by simulated pumping in isolation of all other effects across the mapped marshlands of the ASA (including locations WTOB1 or WTOB2) is greater than 2 m; and/or
- The “cumulative” drawdown (mean annual average drawdown), accounting for the effects of climate and all groundwater pumping across the mapped marshlands of the ASA (including locations WTOB1 or WTOB2), is greater than 2.0m.

The likelihood (probability of exceedance) descriptors are presented in **Table 8-5** and are in reference to the consequence; for example, if the P50 drawdown is 0.08m, but the P10 to P90 range varied from 0.00 to 0.15m, as the consequence threshold from minor to moderate (being 0.1m) is breached within the P90 criteria then the likelihood of modelled drawdown being 0.15 is regarded “as likely as not“ to occur and the risk would therefore be “medium”.

Table 8-5 Risks Matrix (Groundwater Dependant Ecosystems)

		Consequence		
		Minor (<0.1m drawdown)	**Moderate (0.1-2m drawdown)**	**Significant (>2m drawdown)**
Probability of Exceedance	**Very unlikely (n ≤ P10)**	Low	Low	High
	as likely as not (P10 > n < P90)	Low	Medium	High
	Very likely (n ≥ P90)	Medium	High	High

Table Notes:
This risk metrics is more conservative than traditional ones used in ERR 2020 where very unlikely and Significant would only be a “medium” risk. It is only high here due to (>2m drawdown) consequence.

Table 8-6 Risks Assessment for GDEs

Time	Climate Scenario	Location of Receptor at Risk	Potential Risk Pathway	Change from Historical Reference Period (Alcoa Pumping)[1]			Comment / Contingency Requirement	Change from Historical Reference Period (Cumulative Pumping)[2]		
				Maximum (worst case) Consequence	Likelihood / Probability	Risk Rating		Maximum (worst case) Consequence	Likelihood / Probability	Cumulative Risk Rating
Years 1-10	Medium	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low	At least 90% of the 150 model runs demonstrate drawdown is less than 0.1m at this location as a result of the proposed pumping activity.	Minor	As likely as not	Low
Years 11-20	Medium	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 21-43	Medium	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-20	Medium	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Minor	As likely as not	Low
Years 1-43	Medium	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Minor	As likely as not	Low
Years 1-10	Medium	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low	The overall risk rating of "medium" is due to the lowest drawdown uncertainty limit (P10) having a maximum potential drawdown of 0.11m. As the median drawdown (P50) here is much lower than this, it would indicate very few of the 150-model realization indicate this 1cm exceedance. Note: Historical groundwater monitoring at this location shows no evidence of historical pumping related impacts (refer **Table 2-3**, and **Section 2.3**), despite past pumping being at much higher rates.	Minor	As likely as not	Low
Years 11-20	Medium	WTOB2	Drawdown of the ASA	Moderate	As likely as not	Medium		As likely as not	Medium	Medium
Years 21-43	Medium	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Minor	As likely as not	Low
Years 1-20	Medium	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Minor	As likely as not	Low
Years 1-43	Medium	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Minor	As likely as not	Low
Years 1-44	Medium	ASA - Lower Anglesea River	Drawdown of the ASA	Minor	As likely as not	Low	Modelling indicates parts of the mid Anglesea River may experience maximum annual change (drawdown) assessed across 10-year blocks to marginally exceed 0.1m as a result of the proposed pumping activity. However, the model also predicts water levels in these areas are likely to be higher (shallower) than observed across the historical (2010-2023) period negating the drawdown impacts. Nevertheless, It will therefore be proposed that observation bores P8 (ASA) and WTOB2 (ASA) and UEVF MB07 (UEVF) will be used within a trigger and contingency plan network to monitor water level behaviours within Mid Anglesea River, refer **Section 10**. Note: The modelling predicts a maximum drawdown of only 4cm (in 90% of the models for all physical monitoring bores in the ASA.	Minor	As likely as not	Low
Years 1-44	Medium	ASA - Mid Anglesea River	Drawdown of the ASA	Moderate	As likely as not	Medium		Moderate	As likely as not	Medium
Years 1-44	Medium	ASA - Upper Anglesea River	Drawdown of the ASA	Moderate	As likely as not	Medium		Moderate	As likely as not	Medium
Years 1-44	Medium	ASA - Lower Salt Creek	Drawdown of the ASA	Moderate	As likely as not	Medium	At the lowest drawdown uncertainty limit (P10), a small area adjacent the mine is modelled to have drawdown >0.1m. However also within this this location is monitoring bore WTOB1 and the maximum P10 drawdown is here is modelled to be 2cm	Moderate	As likely as not	Medium

Time	Climate Scenario	Location of Receptor at Risk	Potential Risk Pathway	Change from Historical Reference Period (Alcoa Pumping)[1]			Comment / Contingency Requirement	Change from Historical Reference Period (Cumulative Pumping)[2]		
				Maximum (worst case) Consequence	Likelihood / Probability	Risk Rating		Maximum (worst case) Consequence	Likelihood / Probability	Cumulative Risk Rating
Years 1-44	Medium	ASA - Mid Salt Creek	Drawdown of the ASA	Minor	As likely as not	Low	(refer **Table 7-7).** Therefore, if there is an exceedance in this area, its spatial area is small and likely to only just exceed 0.1m. If only median drawdown was considered (P50), all areas in this location have a modelled drawdown <0.1m**.**	Minor	As likely as not	Medium
Years 1-10	High	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low	At least 90% of the 150 model runs demonstrate drawdown is less than 0.1m at this location as a result of the proposed pumping activity.	Minor	As likely as not	Low
Years 11-20	High	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 21-43	High	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-20	High	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-43	High	WTOB1	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-10	High	WTOB2	Drawdown of the ASA	Minor	As likely as not	Medium	The overall risk rating of "medium" is due to the lowest drawdown uncertainty limit (P10) having a maximum potential drawdown of 0.22m. As the median drawdown (P50) here is much lower than this, it would indicate very few of the 150-model realization indicate this exceedance. Note: The level (variability) in uncertainty under high climate change is much greater than medium climate change. Historical groundwater monitoring at this location shows no evidence of historical pumping related impacts (refer **Table 2-3**, and **Section 2.3**), despite past pumping being at much higher rates.	Moderate	As likely as not	Medium
Years 11-20	High	WTOB2	Drawdown of the ASA	Minor	As likely as not	Medium		Moderate	As likely as not	Medium
Years 21-43	High	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-20	High	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-43	High	WTOB2	Drawdown of the ASA	Minor	As likely as not	Low		Moderate	As likely as not	Medium
Years 1-44	High	ASA - Lower Anglesea River	Drawdown of the ASA	Minor	As likely as not	Low	Under severe climate change, modelling indicates parts of the mid Anglesea River may experience maximum annual change (drawdown) assessed across 10 year blocks to marginally exceed 0.1m as a result of the proposed pumping activity. It will therefore be proposed that observation bores P8 (ASA) and WTOB2 (ASA) and UEVF MB07 (UEVF) will be used within a trigger and contingency plan network to monitor water kevel behaviours within Mid Anglesea River, refer **Section 10**.	Moderate	As likely as not	Medium
Years 1-44	High	ASA - Mid Anglesea River	Drawdown of the ASA	Moderate	As likely as not	Medium		Moderate	As likely as not	Medium
Years 1-44	High	ASA - Upper Anglesea River	Drawdown of the ASA	Moderate	As likely as not	Medium		Moderate	As likely as not	Medium
Years 1-44	High	ASA - Lower Salt Creek	Drawdown of the ASA	Minor	As likely as not	Low	The majority of model estimates indicates that across the Salt Creek catchment, drawdown of the ASA water table does not exceed 0.1m as a result of the proposed pumping. Lower Salt Creek was moderate Alcoa impact above under median climate change? Note: Under a median climate change, a mall section of lower salt creek near the mine void indicated a moat risk (exceedance of 0.1m drawdown) this is not seen here	Moderate	As likely as not	Medium
Years 1-44	High	ASA - Mid Salt Creek	Drawdown of the ASA	Moderate	As likely as not	Medium		Moderate	As likely as not	Medium

[1]Risk determined from modelling - subtracting Scenario 2 (Barwon Water only pumping) from Scenario 3 (Alcoa + Barwon Water pumping) model outputs**.**

[2]Risk determined from Scenario 3 model outputs (Alcoa + Barwon Water pumping plus climate change)

8.1.2 Risks of Acid Generating Events

The natural or artificial lowering of water tables, below those typically experienced under natural conditions with seasonal fluctuations, can lead to acidification of soil and groundwater in areas where these sub-surface environments contain appreciable amounts of sulfide minerals (Shand et al, 2018). To assess the risks of acid generating events the following criteria will therefore be used:

- **Minor Consequence**, where:
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is no more than 0.1m greater than the historical range (2010 to 2023) caused by Alcoa's simulated pumping in isolation of all other effects, such as climate and other groundwater users;
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is no more than 0.1m greater than the historical range (2010 to 2023) caused by cumulative pumping and other effects such as climate; and/or
  - No reduction observed in annual zero-flow days relative to the 2010-23 historical period.
- **Moderate Consequence**, where:
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is between 0.1 and 0.5m greater than the historical range (2010 to 2023) caused by Alcoa's simulated pumping in isolation of all other effects, such as climate and other groundwater users;
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is no more than 0.5m greater than the historical range (2010 to 2023) caused by cumulative pumping and other effects, such as climate; and/or
  - Between zero and 10 percent reduction observed in mean annual zero-flow days relative to the 2010-23 historical period.
- **Significant (High) Consequence**, where:
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is more than 0.5m greater than the historical range (2010 to 2023 caused by Alcoa's simulated pumping in isolation of all other effects, such as climate and other groundwater users);
  - The seasonal variability of the ASA water table (WTOB1 and WTOB2) is more than 0.5m greater than the historical range (2010 to 2023 caused by cumulative pumping and other effects, such as climate; and/or
  - Greater than 10 percent reduction observed in zero-flow days relative to the 2010-23 historical period.

The resulting risk matrix is shown in **Table 8-7**.

Table 8-7 Risks Matrix (Acid Generating Events)[11]

		Consequence		
		Minor	**Moderate**	**Significant**
Probability of exceedance	**Very unlikely (n ≤ P10)**	Low	Low	Medium
	as likely as not (P10 > n < P90)	Low	Medium	High
	Very likely (n ≥ P90)	Medium	High	High

[11] Note the risk categories are slightly different to the matrix used to assess impacts to GDEs, which is based on the DELWP 2015 Guidelines. The consequence descriptors in the above table are more conservative i.e. have a lower range, thus the significance of the consequence is reduced.

Table 8-8 Risks Assessment for Acid Generating Events

Time	Climate Scenario	Location of Receptor at Risk	Increase in Seasonal Variability of Watertable Fluctuation (Alcoa Pumping)[1]			Comment / Contingency Requirement	Increase in Seasonal Variability of Watertable Fluctuation (Cumulative Pumping)[2]			Change in Zero Flow Days (Cumulative Pumping)[2]		
			Maximum Consequence	Likelihood / Probability	Alcoa Only Risk Rating		Maximum Consequence	Likelihood/ Probability	Risk Rating	Maximum Consequence	Likelihood/ Probability	Cumulative Risk Rating
Years 1-10	Medium	SV2 / WTOB1	Minor	As likely as not	Low	Generally, and on the basis of the uncertainty analysis, there will be a decrease in zero flow days (more flowing days) compared to 2010 to 2023. However, and despite the median (P50) indicating more flowing days, there is a wide range of uncertainty with this metric and on occasion (defined by outputs within the P50 to P10 uncertainty band) the moderate or significant consequence metrics are met.	Moderate	As likely as not	Medium	Moderate	As likely as not	Medium
Years 11-20	Medium	SV2 / WTOB1	Minor	As likely as not	Low		Moderate	As likely as not	Medium	Moderate	As likely as not	Medium

Years 1-43	High	AV2 / WTOB2	Minor	As likely as not	Low	With reference to water table variability, external factors outside the control of Alcoa are responsible for a moderate consequence metrics to be met.	Moderate	As likely as not	Medium	Significant	As likely as not	High

[1]Risk determined from modelling subtracting Scenario 2 (Barwon Water only pumping) from Scenario 3 (Alcoa + Barwon Water pumping) model outputs.

[2]Risk determined from Scenario 3 model outputs (Alcoa + Barwon Water pumping plus climate change)

8.1.3 Reduction in Surface Water Flows

Changes to stream flow dynamics have also been used to inform the risk of increasing acid generating events; specifically, the following criteria has been used:

- **Minor Consequence**, where:
  - No reduction observed in annual zero-flow days relative to the 2010-23 historical period;
- The mean annual absolute flow rate difference measured against the baseline period is less than 5 percent as a result of Alcoa pumping (in isolation from climate and other groundwater users), measured at AV2 and SV2; and/or
  - The mean annual absolute flow rate measured against the historical period (2010 – 2023) has a difference less than 5 percent as a result of the "cumulative" pumping and climatic factors, measured at AV2 and SV2.
- **Moderate Consequence**, where:
  - Between zero and 10 percent reduction observed in mean annual zero-flow days relative to the 2010-23 historical period;
- The mean annual absolute flow rate difference measured against the baseline period is greater than 5 percent but less than 20 percent as a result of Alcoa pumping (in isolation from climate and other groundwater users), measured at AV2 and SV2; and/or
  - The mean annual absolute flow rate measured against the historical period (2010 – 2023) has a difference greater than 5 percent but less than 20 percent as a result of the "cumulative" pumping and climatic factors, measured at AV2 and SV2.
- **Significant (High) Consequence**, where:
  - Greater than 10 percent reduction observed in zero-flow days relative to the 2010-23 historical period;
  - The mean annual absolute flow rate difference measured against the baseline period is greater than 20 percent as a result of Alcoa pumping (in isolation from climate and other groundwater users), measured at AV2 and SV2; and/or
  - The mean annual absolute flow rate measured against the historical period (2010 – 2023) has a difference greater than 20 percent as a result of the "cumulative" pumping and climatic factors, measured at AV2 and SV2,

The resulting risk matrix is shown in **Table 8-9**.

Table 8-9 Risks Matrix (Surface Water Flows)[12]

		Consequence		
		Minor	**Moderate**	**Significant**
Probability of Exceedance	**Very unlikely (n ≤ P10)**	Low	Low	Medium
	as likely as not (P10 > n < P90)	Low	Medium	High
	Very likely (n ≥ P90)	Medium	High	High

[12] Note the risk categories are slightly different to the matrix used to assess impacts to GDEs, which is based on the DELWP 2015 Guidelines. The consequence descriptors in the above table are more conservative i.e. have a lower range, thus the significance of the consequence is reduced

Table 8-10 Risks Assessment for the Reduction in Surface Water Flows

Time	Climate Scenario	Location of Receptor at Risk	Reduction in Surface Water Flow (Alcoa Pumping)[1]			Comment / Contingency Requirement	Reduction in Surface Water Flow (Cumulative Pumping)[2]			Change in Zero Flow Days (Cumulative Pumping)[2]

8.1.4 Pit Water Quality

The quality of water used to fill the mine void will potentially influence the chemistry of the developing water body. PHREEQC is a geochemical modelling program which can be used to assess the effects of mixing varying volumes of different quality water sources in conjunction with evaporation to estimate how the future water body quality will evolve.

The following sections provide a summary of the geochemical modelling approach used to develop a PHREEQC model coupled with outputs from the 2024 Anglesea groundwater model (**Section 7**). Volumetric outputs obtained from the numerical model (**Table 8-11**) and surface water and groundwater quality inputs were used to assess water body quality recovery under a 12-month UEVF fill scenario using groundwater abstracted from the UEVF. This scenario was selected as it represents using UEVF water as the largest proportion of water used to fill the water body and therefore has the greatest potential for geochemical reactivity to occur between the two water types.

The data covered a time frame of 12 months and a final water body elevation of 5.5 mAHD. The data was provided as 2 weekly timesteps for a total of 24 timesteps during the augmentation period.

Note: this high level mine pit water quality assessment is provided for the purpose of assessing the potential impact of 'the use' of water under any amended Alcoa license, the final and long-term water quality for the mine water body will be further assessed as part of the final Mine Rehabilitation and Closure Plan (and following a confirmed water body filling strategy).

Table 8-11 Water Volume Inputs and Outputs Over 12 Months

Water Balance Data		Volumes (ML)
Natural Inputs		
1	Leakage from ASA	<1[13]
2	Natural groundwater inflow into the waterbody (from DBG)	455
3	Natural groundwater inflow into the waterbody (from UEVF)	626
4	Rainfall input to water body	301
5	Side wall run-off into water body	2.5
Natural Inputs Total		1,384.5
Augmented (modelling purposes only) UEVF Groundwater		17,464
Natural Outputs		
6	Evaporation output from water body	422
7	Pit water loss back into DBG	36

[13] During the augmentation period, groundwater contribution from the alluvial swamp aquifer (ASA) was negligible (less than $2x10^{-4}$ ML per timestep or 0.0048 ML annually) and was discounted from the water balance calculations.

The geochemical modelling of the interaction of the existing water body and UEVF groundwater (as summarised in Table 3-3) included speciation and acid-base reactions. It was not kinetically constrained i.e. reactions were immediate and completed to equilibrium.

The water body that has developed within the pit void is a combination of rainwater and groundwater. A proportion of the rainfall has interacted with the sidewalls before infiltrating the side walls or discharging to the water body as run-off. Recovering groundwater levels have also contributed to the water body. Both rainfall and groundwater have interacted with the unconsolidated backfill material. The groundwater is likely to be in chemical equilibrium with the surrounding material, however, the redox potential and conversion of reduced iron species to oxidised (ferrous) species is the main source of acidity. Other metal species which contribute to the acidity balance are aluminium, manganese and iron. There is a significant temporal record of pH within the water body and based on the stability of pH over the decades it is not anticipated that there will be any significant changes to the current chemistry of the water as it naturally develops.

8.1.4.1 Water Quality Inputs

Water quality data was used from a single groundwater and surface water monitoring event in early November 2022 as it is the most recent data captured using the broad analytical suite and samples from both the UEVF and DBG aquifers. The largest contributors to the developing water body (the waterbody itself and the UEVF), under an augmentation scenario, also have stable geochemistry profiles over time.

Major and selected minor ions were used to characterise the water inputs. The major ions were used to ensure an acceptable ionic balance and the minor ions for the acid producing and buffering characteristics (**Table 8-12** and **Table 8-13**).

Table 8-12 Water Composition – Major Ions

Sample Location	Date	pH	Sodium mg/L	Potassium mg/L	Calcium mg/L	Magnesium mg/L	Chloride mg/L	Sulfate (as SO4) mg/L	Alkalinity (as CaCO3) mg/L

8.1.4.2 PHREEQC Model Development

The geochemical conceptual model for the water body development was based on an assumed input of water at each timestep of water quality derived from the DBG, UEVF, and rainfall and the ratios (or volumes) from the 2024 Anglesea groundwater model. Water (as H_2O) was removed at each timestep as evaporation. Solution composition was equilibrated with mineral species and atmospheric gasses at each timestep. Oversaturated (SI>0) mineral phases were removed (precipitated) from the solution. At the end of each timestep a proportion (as a ratio for the next timestep simulation) of the final solution composition was used to form the water body component of the next timestep. In total 24 timesteps (representative of 1 year) were simulated. The Minteq version 4 database was used for all simulations.

8.1.4.3 PHREEQC Outputs

The water body quality development over the 24 timesteps (indicative time period only represented from 1 January 2023 to 1 January 2024) has been plotted in **Figure 8-1** (major ions) and **Figure 8-2** (minor ions) below. As the volume of the water body increases with the addition of groundwater and surface water, fluctuations in major and minor ion chemistry are observed.

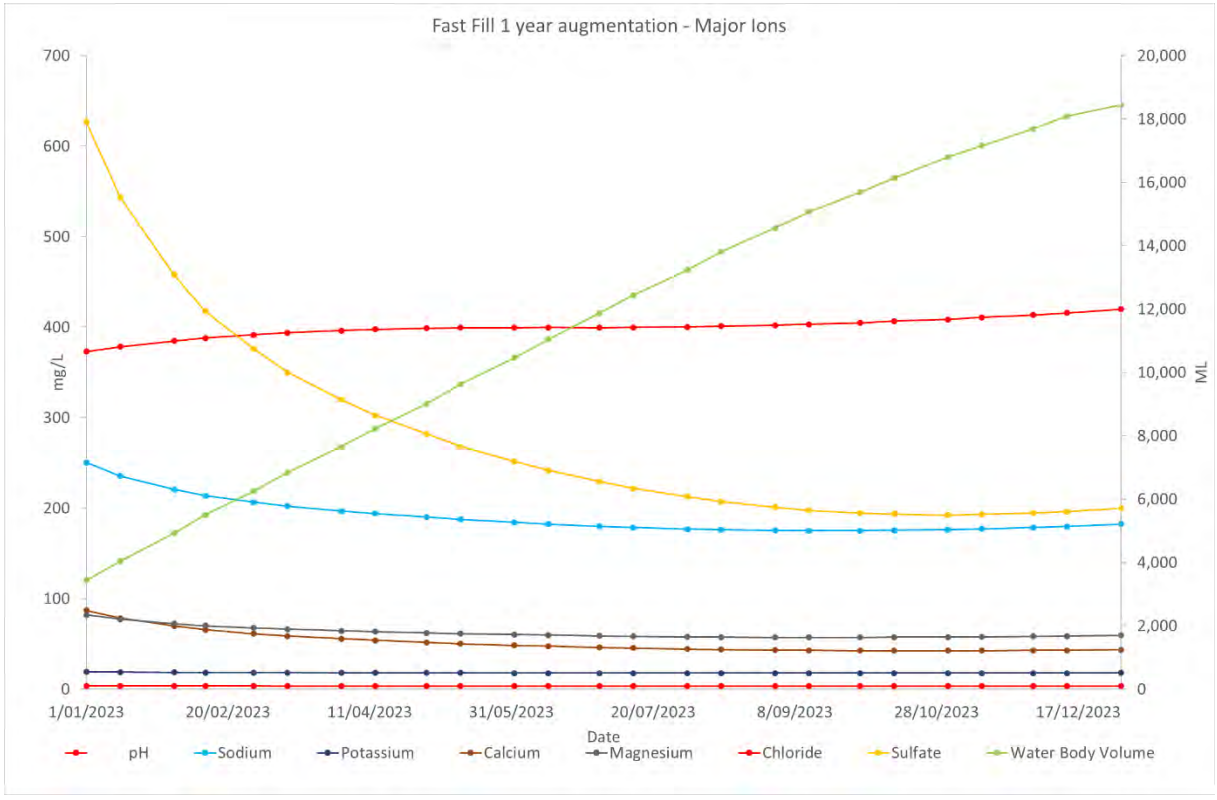

Figure 8-1 Fast Fill 1 Year – Major Ions

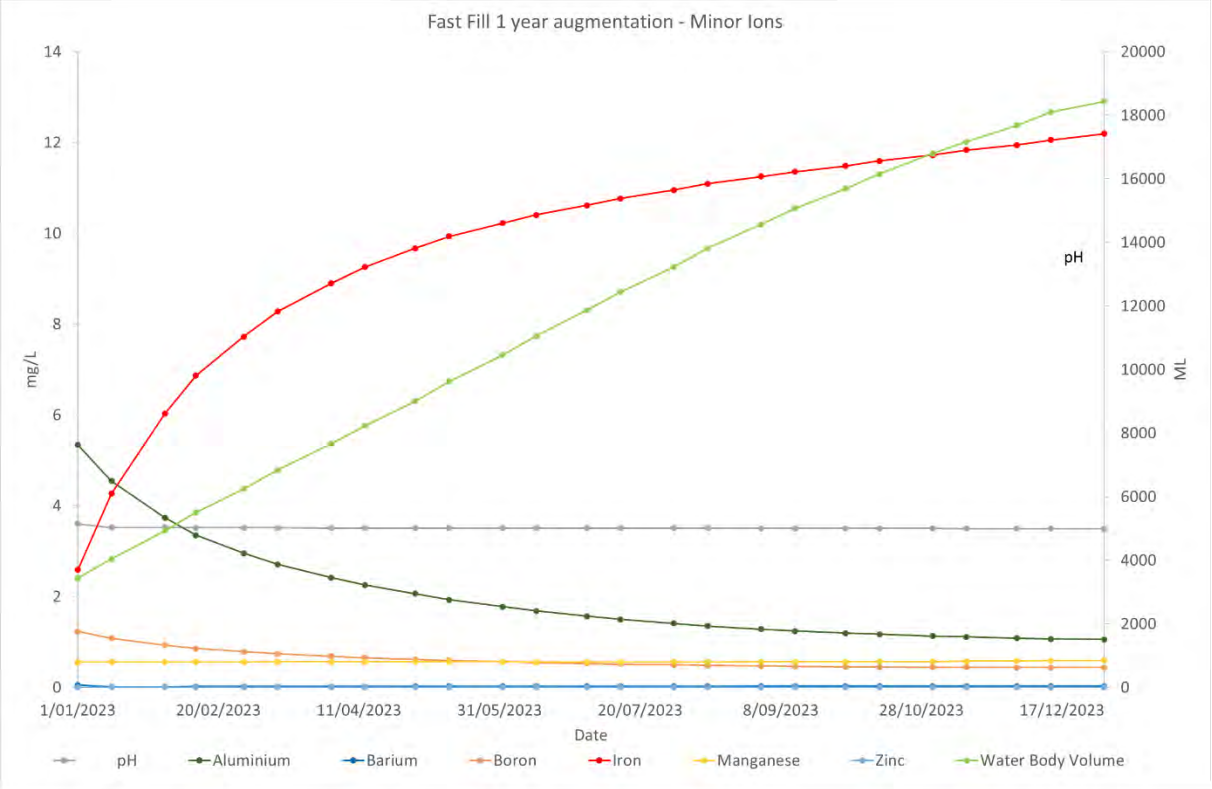

Figure 8-2 Fast Fill 1 Year – Minor Ions

8.1.4.4 Additional Scenarios

In addition to the 12 months scenario, 4- and 10-year fill scenarios were also simulated using an extrapolation of the original numerical model data (**Table 8-14**). This assumption will underestimate the natural inflow contributions, particularly from the UEVF; however, the augmentation volume has compensated for this shortfall. Rainfall contribution will increase over time and sidewall runoff will decrease; however, these are proportionally minor volumes compared to augmentation. Evaporation will also increase over time, so evapo-concentration is underestimated.

8.1.4.5 Model Simulation Conclusion

Although the pH of the UEVF water is only slightly acidic (pH 6.82), the potential acidity loading is high based on the concentration of iron (and to a lesser extent aluminium, manganese, and zinc). The overall increase in iron concentration at the end of the augmentation period is sufficient to maintain the acidic nature of the water body with a slight decrease in the pH from 3.6 to pH 3.5.

The final water body quality is improved with lower concentrations of aluminium (5.34 mg/L to 1.06 mg/L), barium (0.05 mg/L to 0.03 mg/L), boron (1.23 mg/L to 0.44 mg/L), zinc (0.58 mg/L to 0.14 mg/L) and major ions (sodium, potassium, calcium, magnesium, and sulfate). The decrease in metal and major ion species is due to dilution (lower concentrations in UEVF groundwater), although precipitation of mineral phases (iron minerals including ferrihydrite) could potentially affect metal concentrations (via co-precipitation) in the long term. There are also increases in the concentrations of chloride (373 mg/L to 420 mg/L), iron (2.59 to 12.19 mg/L), and manganese (0.56 mg/L to 0.60 mg/L).

Table 8-14 Comparison of One, Four, and Ten Year Fill Scenarios

Fill Scenario	pH	Na	K	Ca	Mg	Cl	SO_4^2	Al	Ba	B	Fe	Mn	Zn

*PHREEQC model precipitates iron (as iron mineral species) if oversaturated, in reality the mine water is supersaturated with iron

9 Conclusions

Rehabilitation of the former Anglesea coal mine is regulated by the *Mineral Resources (Sustainable Development) Act 1990*. This Act is overseen by Resources Victoria and the ERR unit, now a part of DEECA. In compliance with Section 79 of the *Sustainable Development Act 1990*, a draft MRCP was developed and submitted to ERR in 2017. Within this Plan, it was presented that water is required to accelerate the filling of the mine void to help achieve the MRCP objectives in a timely manner.

Since then, additional studies and rehabilitation objectives (e.g., earthworks and revegetation) have been separately completed, with a defined and approved water filling strategy now the outstanding item inhibiting the finalisation of the MRCP. These additional studies have also confirmed that sustainable UEVF groundwater extraction is the only feasible option to accelerate the filling of the mine void. Left to fill naturally, the mine void would take many decades to fill.

As such and in accordance with Section 51 of the *Water Act 1989* which deals with sustainable, efficient, and equitable management and allocation of the water resources, Alcoa are seeking to obtain approval from Southern Rural Water (the Responsible Authority) to amend the existing Groundwater Licence (BEE029662), from 4000 ML/yr to 1,500 ML/yr (for 10 years) and amend its use to allow this groundwater to accelerate filling of the former Anglesea coal mine to help achieve the MRCP objectives.

To ensure the reduced and amended allocation poses no unacceptable risks or adverse impacts to the environment that may rely on groundwater, a groundwater impact assessment has been developed in accordance with EPA Victoria Publication 688.1 Hydrogeological assessment guidelines for groundwater quality and Section 59A of the *Water Act (1989)*.

The key findings from this GIA are summarised below and are based on:

- Multiple independent technical assessments conducted in the region relevant to potential groundwater impacts (**Section 2.3**);
- Detailed assessment of long term water level, water quality, climate and surface water flow observation data from more than 130 groundwater monitoring point and available surface water flow sources (**Section 4**);
- Significantly improved Conceptual Hydro-geological Model for the Alcoa area of interest that which has been subject to and endorsed by the regulator Inter Agency Group appointed independent TRP; (**Section 6** and **Appendix A**);
- Predictive tools such as the updated 2024 Anglesea Groundwater Numerical Model, which has also been subject to and endorsed by the TRP comprised of independent experts from a wide range of fields including geology, hydrogeology, modelling, geochemistry, and ecology. The TRP was selected by an Inter Agency Group, representing the Water and Catchments Group of DEECA, Earth Resources Regulation, and Southern Rural Water (**Section 7** and **Appendix B**);
- Hydrogeological risk assessment including for proposed Alcoa groundwater extraction, including applying the relevant medium and high climate change models (**Section 8**);
- The results of a purpose designed groundwater pumping test completed in 2021 that was subject to significant regulatory oversight (Appendix D of **Appendix A**); and
- The feedback from on-going and recent community engagement processes and events (**Section 2.4**).

9.1 Key Findings

General Findings (including consideration from ongoing monitoring post pumping test):

- In the Anglesea River and Salt Creek valleys, younger alluvial deposits overlie the regional aquifer-systems and are referred to as the Alluvial Swamp Aquifer (ASA). The ASA supports the dense swampland vegetation as well as comprising naturally occurring sulphide-bearing sediments, peat and coal. As the groundwater level fluctuates in the ASA, mostly driven by climatic variations, these sediments are exposed to air and oxidised in the vadose zone. This happens over and over again, resulting in a build-up of leachable acid and metals. When the ASA becomes fully saturated (usually after a significant wet period), these oxidised sediments are mobilised resulting is low pH (acidic) water.
- Despite the ASA in the lower reaches of the Anglesea Catchment having consistently recorded pH between 2.5 and 4 since 1967, the Anglesea River estuary had previously been artificially supported by a 3-5 ML/day of approximately pH 7 water discharged from Alcoa's power station (EPA License EM32162). This activity, which ceased in 2016 has historically buffered upgradient low pH conditions.
- A well established and understood baseline of groundwater elevation data exists across the site. This data also spans across numerous external groundwater stress periods that have operated at much greater stresses (i.e., groundwater extraction rates) than what is being proposed as part of this amended application. As a result of these stresses, no observable or statistically significant trends can be identified in the existing groundwater observation network for the ASA. Simply, groundwater behaviours in these shallow aquifers have remained relatively consistent with seasonal variations, with climate (e.g., rainfall) influencing its behaviour.
- At the deepest part of the mine void, during the course of the coal mining, a clay unit (referred to as the basal clay) underlying the mined coal seam which inhibits vertical groundwater movement was likely extracted and a "sump pump" installed in this location to keep the mine void dry; as a result, this sump pump was not only removing local catchment runoff and shallow groundwater ingress, but also likely dewatering the thin upper sand layers of the UEVF.

Numerical Model Findings

- Progressive mining operations between 1980 and 1985 in the northwest corner of the mine and closest to the original part of Salt Creek may have increased connectivity between the surrounding aquifers in this location and the mine void. Conversely, modelling also predicts that once the mine is full of water in this region, leakage from theses surrounding near void shallow aquifers into the void would cease meaning post rehabilitation, any groundwater that may have been lost to the mine void, can stay in the groundwater system.
- In the regions of the ASA where water balance modelling predicts Alcoa's pumping may have the largest impact, the potential increase in leakage from the ASA is calculated as:
  - 0.43 mm/yr (0.86% of the calibrated recharge rate) for the mid-section of Salt Creek.
  - 0.75 mm/yr (1.25% of the calibrated recharge rate) for the mid-section of Anglesea River.
- The formation of pit water body poses no adverse risks from a pit water quality perspective with minimal change to the existing pH of 3.6, and the final water body quality having modelled lower concentrations of aluminium, barium, boron, zinc and major ions (sodium,

potassium, calcium, magnesium, and sulfate). Only minor increases chloride, iron, and manganese are modelled.

- Using groundwater to accelerate the filling of the water body poses no adverse risks to surrounding groundwater quality with only 35 particles (out of 45 million modelled) potentially progressing a distance into the aquifer extending beyond the mine lease boundary. The mine water body has been modelled to act as a groundwater sink.
- Under a medium climate change scenario and using the top 150 groundwater model solutions from the 2024 Anglesea Groundwater model, and as a result of simulated Alcoa groundwater pumping only, the following conclusions are made:
  - The median (P50) drawdown at all observation bores within the ASA have modelled drawdown <0.1m resulting in a low consequence of impact to GDEs as defined by the 2015 Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems.
  - When considering uncertainty, e.g. the P10 limit which takes into consideration 90 percent of model realisations), WTOB2 and P7/P7B are modelled to have a maximum potential drawdown of 0.11m. As the median drawdown here is much lower than this, it would indicate very few of the 150-model realization indicate this 1cm exceedance. It is important to note that historical groundwater monitoring at this location shows no evidence of historical pumping related impacts.
  - At both WTOB1 and WTOB2 there is insignificant to no reduction in the seasonal water table depth (P10-P90) range over the forecast model period.
  - Forecast zero flow days at SV2 and AV2 (using models within P10 - P90) are generally the same as or fewer (meaning more flow days) than over the historical 2010-2023 period.
  - Modelled annual flows at SV2 (using models within P10 - P90) are expected to be generally higher than historical rates indicating groundwater extraction has an inconsequential impact on flows within the Salt Creek catchment.
  - Modelled annual flows at AV2 (using models within P10 - P90) suggest a possible minor (<5 percent) portion of flow reduction over the historical 2010-2023 period.
  - For locations in the ASA that do not have a physical observation point (such as a groundwater observation bore), the only areas simulated to experience modelled drawdown from the proposed pumping activity where water table levels are below historically observed depths, are two small tributaries in the middle Anglesea swamplands and the upper-mid sections of the Anglesea River swamplands. Most of the other areas of the ASA and swamplands are simulated to experience similar or slightly shallower (higher) water table depths than historical conditions.
  - A water balance undertaken as part of QOI #4, estimated groundwater contribution from the alluvial swamp aquifer (ASA) was negligible (0.0048 ML annually) supporting historical conceptualisation that baseflow either to or from the ASA into groundwater is insignificant.
- Under a high climate change scenario and using the top 150 model solutions from the 2024 Anglesea Groundwater model, as a result of simulated Alcoa groundwater pumping only:
  - The median (P50) drawdown at all observation bores within the ASA have modelled drawdown <0.1m resulting in a low consequence of impact to GDE as defined by the 2015 Ministerial Guidelines for Groundwater Licensing and the Protection of High Value Groundwater Dependent Ecosystems.
  - When considering uncertainty, e.g., the P10 limit which takes into consideration 90 percent of model realisations), the largest drawdown is modelled to be 0.22m (WTOB2). It is important to note that historical groundwater monitoring at this location shows no evidence of historical pumping related impacts.

- At both WTOB1 and WTOB2 there is insignificant to no reduction in the seasonal water table depth (P10-P90) range over the forecast model period.
- Forecast zero flow days at SV2 and AV2 (using models within P10 - P90) are generally the same as or fewer (meaning more flow days) than over the historical 2010-2023 period.
- Modelled annual flows at SV2 (using models within P10 - P90) are expected to be generally higher than historical rates indicating groundwater extraction has in consequential impact on flows within the Salt Creek catchment.
- Modelled annual flows at AV2 (using models within P10 – P90) suggest a possible minor (<5 percent) portion of flow reduction over the historical 2010-2023 period.
- For locations in the ASA that do not have a physical observation point (such as a groundwater observation bore), the only areas simulated to experience drawdown from the proposed pumping activity water table levels below historically observed depths are two small tributaries in the middle Anglesea swamplands and the upper-mid sections of the Anglesea river swamplands. Most other areas of the ASA and swamplands are simulated to experience similar or slightly shallower (higher) water table depths than historical conditions.

When cumulative impacts are considered (climate, Barwon Water LEVF, Alcoa UEVF), some increased risks to GDEs, surface water flows and potential acid generating events are observed. While the licencing and approval of a LEVF BE is outside the control of Alcoa and the Responsible Authority being Southern Rural Water (SRW), it is nevertheless included for completeness in this GIA. For reference, the LEVF BE it is currently going through a separate review by Barwon Water and Alcoa understands that it will be subject to approval by the Minister for Water under the *Water Act 1989*. Cumulative risks may also be managed via the inclusion in any entitlements (Barwon Water and Alcoa) appropriate adaptive monitoring and risk mitigation plans as described below.

Considerate of all of the above, this GIA is also based on multiple lines of evidence to inform risk, such as:

- Groundwater mounding in the ASA following significant rainfall or flow events is not observed from daily monitoring groundwater data adjacent to the alluvial creek systems near the former power station, indicating in this area these leakage rates from the ASA to underlying aquifers is not a significant migration pathway.
- Isotope analysis of residual water pools in the ASA (or creek systems) indicated that these pools were not supported by groundwater; rather, they are surface water fed located in areas of low potential evapotranspiration.
- Groundwater levels for all monitored locations in the ASA responds closely to seasonal rainfall, declining when the proceeding months are low in rainfall and/or evapotranspiration is likely high.
- Groundwater level trends in the ASA are similar regardless of if the underlying UEVF potentiometric surface is higher or lower than the water table in the ASA.
- Continuous pressure monitoring data from Vibrating Wire Piezometers (VWPs) from above the main coal seam (in the Demons Bluff Group) from 1999 to 2011 as well as those installed around the former power station from 2006 show no response to UEVF groundwater extraction.
- The Alcoa groundwater pumping test conducted during 2021 with close oversight from the regulator and Technical Working Group identified no adverse impacts on groundwater dependent eco-systems including the Anglesea River.

Therefore, and in recognition of all the lines of evidence, an amended groundwater entitlement of 1,500 ML/yr for 10 years to accelerate the filling of the former Anglesea mine void poses low risk of adverse environmental impact to groundwater dependent ecosystems (including the Anglesea River).

Recognising however that the ASA (GDE's and Anglesea River) are sensitive receptors, and that groundwater extraction does present a risk (albeit low as described throughout), it is proposed to adopt an adaptive water management and monitoring program as a key ongoing monitoring, reporting and control measure.

10 Monitoring, Risk Mitigation, and Contingency Plan

This section has been prepared to address the proposed adaptive water management and monitoring program requirements for the period of the amended license entitlement application.

It is proposed that as part of any amended groundwater licence, one of the key conditions would include an updated adaptive management and monitoring plan, including trigger levels and actions which must be provided to SRW and accepted by SRW prior to any extraction occurring under this licence. The development of the trigger levels and action plans will also be considerate of the identified potential beneficial uses of the site.

In the event that an amended license was approved and provided to Alcoa, then Alcoa proposes that it would be required to prepare a detailed adaptive water management and monitoring plan including clearly identified monitoring locations, triggers, actions and contingency plans and seek approval from Southern Rural Water prior to the commencement of any future extraction. Alcoa anticipates this would be similar to the process that preceded the 2021 Alcoa groundwater pumping test. As a pre-cursor to this Alcoa offers the following for future consideration only.

10.1 Potential Risks and Mitigation Measures

As outlined in **Section 8**, as a result of the proposed groundwater licence entitlement and under a median climate change scenario, there are very few risks of moderate or higher consequence to either GDEs or surface water flow dynamics (including the generation of acidic events). This is also supported by long term groundwater elevation behaviour in the shallow (unconfined) and ASA at key parts of the catchment. For example:

- Isotope analysis of residual water pools in the ASA (or creek systems) indicated that these pools were not supported by groundwater; rather, they are surface water fed located in areas of low potential evapotranspiration.
- Groundwater levels for all monitored locations in the ASA responds closely to seasonal rainfall, declining when the proceeding months are low in rainfall and/or evapotranspiration is likely high.
- Groundwater level trends in the ASA are similar regardless if the UEVF potentiometric surface is higher or lower than the water table in the ASA.
- Continuous pressure monitoring data from Vibrating Wire Piezometers (VWPs) from above the main coal seam (in the Demons Bluff Group) from 1999 to 2011 as well as those installed around the former power station from 2006 show no response to UEVF groundwater extraction.

Despite this, the numerical modelling suggests that under future modelled median climate change conditions, as a result of the proposed extraction, the ASA located in the mid part of the Anglesea River has a slightly elevated risk profile (i.e., the low risk [inclusive of P10-P90 uncertainty]) drawdown threshold is exceeded (i.e., 0.1m drawdown).

To monitor this potential risk, it is proposed that continuous (daily; via pressure transducers with data logging capability such as a Solonist Levelogger) groundwater level and pressure monitoring be undertaken in key observation bores that were defined for the 12-month pumping test undertaken in 2021. In addition, it is proposed that monitoring bores including Barwon Water bores P7B, P8, P12, P17 and P19 are also to be included. These are shown on **Figure 10-1** and **Table 10-1**.

Table 10-1 Monitoring Bore Network Construction Details and Modelled Drawdown

Table Notes:

*DEECA have removed this bore from the State Observation Bore Network due to integrity issues and will likely be decommissioned. However, until such time, this bore will be retained as it contains significant historical data and despite its history of casing integrity issues, there is value in maintaining this data to assist only with decision-making processes.

Electronic files are provided for information only.

10.2 Groundwater Monitoring, Trigger Levels, and Contingency Measures

As discussed in **Section 10.1**, the ASA located in the mid part of the Anglesea River has a slightly elevated risk profile. Fortunately, in this location there are a series of nested groundwater observation bores that contain greater than 10 years of high frequency data (included in the proposed observation bore network detailed in **Table 10-1**). This data also spans numerous external groundwater stress periods that have operated at **much greater stresses** (i.e., groundwater extraction rates) than what is being proposed as part of the entitlement application; such as:

- LEVF extraction during 2011 and 2012; 2022.
- UEVF extraction 1969 to 2015; 2021.

Therefore, it is proposed to incorporate these bores into a management and monitoring contingency framework.

Typically, and as part of a monitoring contingency and response plan, water triggers are developed. These triggers are designed to prompt investigations, implement further monitoring or undertake mitigation actions. However, across the catchment, the established and extensive groundwater baseline conditions indicate that the above historical stresses have not caused an observable change in groundwater level trends in the shallow ASA monitoring bores. Furthermore, the numerical modelling predicts potential drawdown impacts within the ASA monitoring locations are considerably less than the natural annual groundwater level variability of the ASA. As such the development of trigger levels based on common approaches such as those using the 20 percentile would be inconsequential. For example, assume a trigger level (based on exceedance of the 20 percentile) was applied to P19 (screened in the UEVF, underlying the ASA) in the mid part of the Anglesea river catchment. As observed in **Figure 10-2 (orange line)**, this is exceeded almost annually and typically in summer, regardless of whether or not there has been groundwater extraction or not.

It is therefore proposed to develop an upper tolerance limit (UTL) using ProUCL software published by the United States Environmental Protection Agency (USEPA), (USEPA, 2015a), (USEPA, 2015b). There exists more than a sufficient dataset to undertake this methodology with the calculation of an UTL, based on the 95 percent upper confidence limit (UCL) for water levels in each proposed observation bore network detailed in **Table 10-1**.

For the calculated UTL triggers, the following contingency steps should be undertaken upon the first or subsequent exceedance of a trigger level:

- In the event of the first trigger level exceedance:
  - Review the data and quality assurance/quality control (QA/QC) to determine whether the result is valid. This should include consideration of:
    - Monitoring Equipment failure or transcription errors.
    - Historical data and data from other bores (i.e., Does the data make sense in the context of historical data or data from other site monitoring bores that are screened in the same formation? Is the result a clear outlier?).
    - Are water quality parameters exhibiting a change.
    - Validity of the trigger level (e.g., Have the trigger levels been based on a sufficient number of representative results? Is further monitoring data required to establish more representative trigger levels?)
  - If the result is potentially not valid, confirm the result through an additional monitoring event (ideally taken within a period of 3 months).
  - If result is valid or subsequent analysis confirms the exceedance, increase the frequency or monitoring from quarterly to monthly.

  - Note: It is proposed to undertake quarterly download and reporting of the data which is logged on a daily timestep (for water level). If an exceedance is observed, download of daily data would happen monthly.
  - Continue monthly water level monitoring until four consecutive results below the trigger level have been obtained.
- In the event of a second consecutive trigger level exceedance:
  - conduct further comparative assessment of climate and water level behaviours to determine whether the result is indicative of groundwater pumping. The assessment should be documented in an internal technical memorandum, which at a minimum should include the following elements:
    - Review and comparison with local trends in groundwater concentrations for other site monitoring bores (including background monitoring bores) and assessment of whether the result is attributed to broader site-wide or regional trends as compared to localised conditions.
    - Review of other factors, as applicable, including potential bore integrity issues (e.g., casing damage, surface water infiltration) or climatic factors.
    - Comparative assessment of other groundwater constituents (e.g., metals concentrations) may also be warranted.
  - If further review determines that the result is likely due to naturally occurring conditions, groundwater trigger levels should be reviewed and updated (based on historical and recent results) using references such as DES guideline *Using monitoring data to assess groundwater quality and potential environmental impacts* (DES, 2021).
  - Monthly reporting should continue until four consecutive results below the trigger level have been obtained.
  - If the further review conducted at this stage determines that the result is likely due to groundwater pumping (i.e., there are clear indications of drawdown), this is classed as a trigger event and an investigation must be undertaken with the results of the investigation submitted to SRW within a practicable timeframe (e.g., within 6 weeks following the notice of a second consecutive trigger level exceedance).
- A third consecutive trigger level exceedance is classed as a trigger event.

A trigger event will result in the cessation of pumping until an investigation is completed.

As mentioned above (and where no triggers are breached), groundwater levels from these bores listed in **Table 10-1** will be reported quarterly (from the dedicated pressure transducers) and verified where possible by manual gauging prior to each groundwater monitoring event. This data will then lead to the development of a factual quarterly report. A bi-annual report (every 2 years) will be produced which will provide further comment on any observed trends or outliers. With respect to water quality, the current quarterly Mine Water Body sampling program will be maintained during the period of the entitlement, unless otherwise agreed with the regulator. Reporting from the period of March to May 2024 is presented in **Appendix G**. This data will be evaluated, and a summary provided in the quarterly report as indicated above.

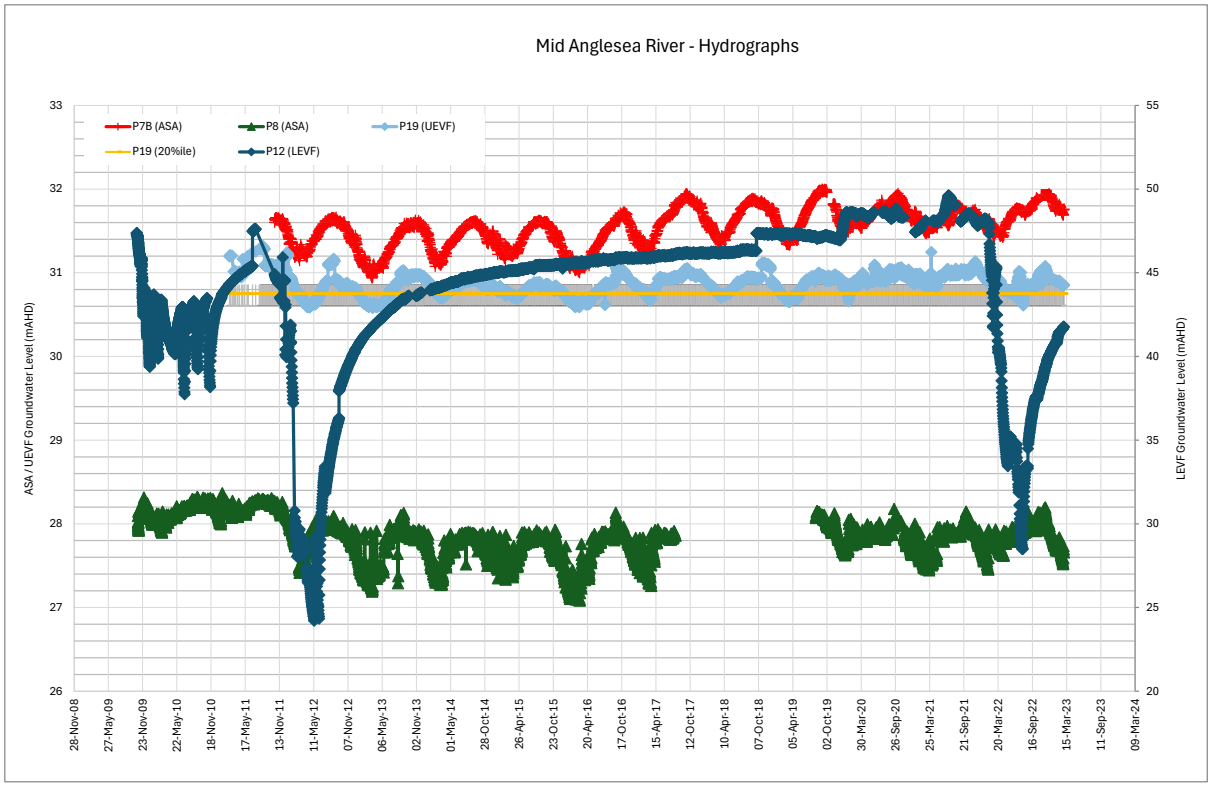

Figure 10-2 Trigger Example

11 Limitations

EHS Support Pty Ltd (“EHS Support”) has prepared this report in accordance with the usual care and thoroughness of the consulting profession for the use of Alcoa of Australia and only those third parties who have been authorised in writing by EHS Support to rely on the report. It is based on generally accepted practices and standards at the time it was prepared. No other warranty, expressed or implied, is made as to the professional advice included in this report.

The methodology adopted and sources of information used by EHS Support are outlined in this report. EHS Support has made no independent verification of this information beyond the agreed scope of works and EHS Support assumes no responsibility for any inaccuracies or omissions. No indications were found during our investigations that information contained in this report as provided to EHS Support was false.

This report was prepared between March 2024 and March 2025 and is based on the conditions encountered and information reviewed at the time of preparation. EHS Support disclaims responsibility for any changes that may have occurred after this time.

This report should be read in full, including appendices. No responsibility is accepted for use of any part of this report in any other context or for any other purpose or by third parties. This report does not purport to give legal advice. Legal advice can only be given by qualified legal practitioners.

This report contains information obtained by inspection, sampling, testing or other means of investigation. This information is directly relevant only to the points in the ground where they were obtained at the time of the assessment.

Where conditions encountered at the site are subsequently found to differ significantly from those anticipated in this report, EHS Support must be notified of any such findings and be provided with an opportunity to review the recommendations of this report.

Whilst to the best of our knowledge information contained in this report is accurate at the date of issue, subsurface conditions, including groundwater levels can change in a limited time. Therefore, this document and the information contained herein should only be regarded as valid at the time of the investigation unless otherwise explicitly stated in this report.

Table of Contents

1 Introduction 1

1.1 Purpose of this Report 1
1.2 Background 1

2 Historical Investigations and Activities 6

2.1 Pre-1960 6
2.2 1960-2016 (Mine Operation) 6
2.2.1 Mine Development Timeline 6
2.2.2 Post-2008 – Barwon Water Groundwater Extraction 11
2.3 Mine Rehabilitation Since 2015 11
2.3.1 Installation of Groundwater Monitoring Bores (2020 / 2021) 12
2.3.2 Catchment Drains 13
2.3.3 Subsidence Monitoring 16
2.3.4 Decommissioning of Site Infrastructure 16
2.4 Summary of Lessons Learnt from Post 2015 MRCP Activities 22
2.4.1 Learnings from Installation of New Observation Bores 22
2.4.2 Learnings from the 6-Month Pumping Test 23
2.4.3 Other Learnings 24
2.5 Summary of Groundwater Investigations 27
2.6 Summary of Surface Water and Catchment Investigations 27
2.7 Data Sets 34
2.7.1 Surface water 34
2.7.2 Groundwater 35
2.7.3 Climate 35

3 Environmental Setting 37

3.1 Topography and Land use 37
3.2 Climate 37
3.2.1 Evaporation on Water Bodies 38
3.3 Climate Change 41
3.4 Soils 42
3.5 Catchment Acidity and Acid Sulphate Soils 42
3.6 Groundwater Users 45
3.7 Potential Environmental Sensitive Receptors and Groundwater Dependant Ecosystems 45
3.7.1 Anglesea River and Salt Creek Permanent Pools 45
3.7.2 Anglesea River and Salt Creek Vegetated Marshlands 46
3.7.3 Anglesea River Estuary 46
3.8 Catchment Hydrology 48
3.8.1 Anglesea River 50
3.8.2 Salt Creek 52
3.8.3 Reduction in Surface Water Flows 56

4 Protected Environmental Values and Water Quality Summary 58

4.1 Environment Protection Act 2017 58

4.1.1 Environmental Values and Adopted Assessment Criteria 58
4.1.2 Relevant Groundwater Segment and Environmental Values 60
4.2 Water Quality Summary 61
4.2.1 Mine Pit Water Quality 61
4.2.2 Catchment Surface Water Quality 64
4.2.3 Groundwater Quality 71

1 Introduction

1.1 Purpose of this Report

This report serves multiple purposes, these are:

- To provide hydrogeological and conceptual data to support a potential groundwater licence application for extraction of groundwater from a bore screened in the Upper Eastern View Formation (UEVF) located at the former Alcoa Power Station and Coal mine.
- To provide input into a risk assessment that will be used to inform water related closure criteria related to Alcoa mine closure and rehabilitation plan (MCRP).
- To provide site specific hydrogeological and other data specific to Alcoa's area of interest (AOI) (refer **Section 5.2.1**) to support the refinement of the Anglesea groundwater model (refer GHD 2022 and section below). Note: to gain greater detailed understanding of the whole catchments hydrogeological understanding is it strongly recommended to read GHD 2013a,b, GHD 2015 and GHD 2020.
  For reference, the Anglesea groundwater model was initially developed by GHD Pty Ltd in 2009 and revised in 2013. The model is a single catchment wide (Jan Juc Groundwater Management Area) numerical groundwater model that was used to determine potential impacts from Barwon Waters Bulk Entitlement from the Lower Eastern View Formation (LEVF). An agreement between Barwon Water and Alcoa was made whereby this updated calibrated model will be provided to Alcoa to allow predictive management scenarios to be undertaken associated with potential extraction of groundwater from the Upper Eastern View Formation (UEVF). As such, the data contained within this report is not intended to cover the whole numerical model domain as Alcoa's interests and potential impacts only cover a small part of the overall catchment. This report does however direct the reader to other studies where a significant amount of data has been collected and presented in support of the model development.

1.2 Background

The former Anglesea Coal Mine (referred to as "the mine") is located approximately 3 kilometres (km) northwest of the Anglesea township in Victoria. Adjacent to the mine is the former Anglesea Power Station (referred to as "the former power station"). The general site layout is shown in **Figure 1-1** and its regional location is shown on **Figure 1-2**.

Alcoa is licensed to extract 4,000 megalitres/year (ML/yr; approximately 11 ML/day) from the Upper Eastern View Formation (UEVF) under Licence Entitlement BEE029662 (also referred to as a Groundwater Licence or a Take and Use Licence) until 30 June 2024 (**Appendix A**). The purpose of use is permitted as industrial or commercial use, as well as industrial and stock but is subject to the groundwater being used on Allotment 64D of the former power station site only (Block 1-4 on **Figure 1-3**).

Filling the mine pit void, which is not located on Allotment 64D, with water remains a key enabler for the draft *Anglesea Mine Rehabilitation and Closure Plan* (MRCP) as submitted to Earth Resources Regulator (ERR) in September 2017.

During the progressive rehabilitation works over the past five years, the mine pit void water level has been slowly rising as forecasted, as a result of natural groundwater recovery, direct rainfall and local catchment runoff only. It is estimated that allowing the mine pit void to naturally fill would take between 50 and 100 years with a final steady state waterbody surface estimated between -4 and +4 metres Australian Height Datum (m AHD) (EHS Support, 2017).

In September 2020, Alcoa submitted a Groundwater Impact Assessment (GIA) evaluating risks to both the environment and third-party users associated with a proposed 12-month groundwater pumping test of the UEVF aquifer. In October 2020, Southern Rural Water (SRW) issued an amended groundwater licence including an Addendum (LH1575619) to the Licence Entitlement BEE029662 and Licence to Operate Works WLE0351661. These three documents are provided in **Appendix B**.

The amended groundwater licence permits the 12-month groundwater pumping test and specifically the extraction of up to 1.5 gigalitres (GL) of water '*for the purposes of discharging groundwater to the mine pit as part of the amended licence'* (**Appendix B**). A condition of the amended groundwater license was that *'An updated monitoring plan, including trigger levels and actions must be provided to SRW and accepted by SRW prior to any extraction occurring under this licence.*' A copy of the Monitoring Plan and Trigger Levels Report is provided in Appendix C.

Alcoa subsequently commenced a groundwater pumping test of the UEVF aquifer on 13 May 2021 to enable further investigation of groundwater use and commence the initial mine pit void filling process. The pumping test was paused on December 8, 2021 after a total of 671.9ML was extracted, representing approximately 44% of the licensed volume. During this period, the findings of the first 6-Months were reviewed.

On September 20, 2022, Southern Rural Water (SRW) refused the application made to undertake the second 6-month period primarily due to "***the aquifer having recovered back to pre-trial levels***" and their view that "***further pumping would likely yield similar results***." Further, SRW sought advice from the independent technical panel (ITP), appointed to review the development and calibration of the Anglesea groundwater model, and they advised "**additional information from the second 6- month period would be of limited benefit because there is sufficient data to have developed and appropriately calibrated a groundwater model that can inform any potential future application for licence amendments**". Further information regarding SRW decision is here: https://www.srw.com.au/news-media/alcoas-groundwater-licence-application-refused

Importantly though, the data gathered during the pumping test has not identified any adverse impacts on groundwater dependent ecosystems, including the Anglesea River.

Therefore, this document outlines the findings from the first six months of the groundwater pumping test **Appendix D** and presents a revised Conceptual Site Model (CSM). The data collated and analysed will be used to refine and re-calibrate an existing regional numerical Anglesea groundwater flow model (in conjunction with Barwon Water) to enable predictions of potential impacts to the environment.

Dependent on the outcomes of the data analysis from the first six months of the groundwater pumping test, and the outputs of the updated Anglesea Groundwater Model, Alcoa is seeking to determine if a sustainable groundwater extraction rate can be achieved and if so proposes to then seek a groundwater license amendment from SRW to support the filling of the mine void.

2 Historical Investigations and Activities

2.1 Pre-1960

Roche Brothers commenced open cut mining operations on the Anglesea coal deposit in the late 1950s. Around the same time the concept for an aluminium smelter at Point Henry was developed (by Western Aluminium NL which became Alcoa of Australia in 1961), about 7 km from Geelong with feedstock alumina to be shipped from Western Australia.

The concept envisaged that the smelter would be supplied with approximately 70% (at that time) of the required electricity from a new generating station to be located at Anglesea and fuelled from the adjacent brown coal mine. In 1960, drilling was undertaken in the Anglesea area and revealed a main coal seam mining area adjacent to the lower seam being operated by Roche Brothers. Assessments at the time showed a coal deposit of about 120 million tonnes, compared with approximately 30 million tonnes assessed by Roche Brothers.

2.2 1960-2016 (Mine Operation)

2.2.1 Mine Development Timeline

The mining rights were obtained by Alcoa of Australia (Alcoa) from Roche Brothers at Anglesea, and on 22 November 1961 the Mines (Aluminium) Agreement Act was passed providing Alcoa the rights to explore and mine over 7,350 hectares of leasehold land largely to the northwest of Anglesea, including the area being mined by Roche Brothers. Power Station construction began in 1965 with the first power produced in March 1969.

The drilling program revealed that the original mining by Roche Brothers was in a lower seam to the west of the main upper seam. As a result, a new mine was opened adjacent to and expanding away from the power station site. Overburden removal was initially used for backfilling the old Roche Brothers open cut mine and to facilitate rehabilitation of the entire Roche Brothers site. **Figure 2-3** shows the progressing mining extents and **Figure 2-4** shows progressive backfilling extents.

In 1969, Alcoa began to pump groundwater from the UEVF to support the operation of the power station and mine. A series of boreholes from 1964 were drilled by Alcoa that were licensed to extract groundwater from the lower aquifers within the Upper Eastern View Formation (UEVF). These extraction bores extracted groundwater used for process and cooling water for the power station, with surplus (treated) process water directed to an Environmental Protection Agency (EPA) licensed discharge and providing baseflow and Alkaline pH water; pH ~7-8, to the Lower Anglesea River. Daily extraction rates from these bores were around 4.5 ML/day with higher extraction rates measured historically. This is presented on **Figure 2-1** and clearly shows the alkaline buffering capacity the Alcoa discharge baseflow had on the pH of the Estuary. Prior to this discharge, these was evidence that these surface water systems periodically turned acidic, **Figure 2-1**.

The historical groundwater extraction bore network at the time comprised of bores WB9, WB10, WB13, WB14, WB15, WB16 and WB17 (**Figure 2-2**). Some of these bores (WB9, WB10, WB13 and WB17) have since been decommissioned (refer **Section2.3.4**). In addition to the extraction bores, Alcoa undertook mine dewatering activities directly from the mine pit. The mine pit, which is excavated to a maximum depth of approximately -45 m AHD, was dewatered from a progressively

moving sump positioned at the lowest part of the operational mine at an extraction rate ranging between 1 to 1.5 ML/day when pumping. This pumping was conducted intermittently, approximately 60 percent of the time (based on in-flows and rainfall).

2.2.2 *Post-2008 – Barwon Water Groundwater Extraction*

The Anglesea Borefield is used to extract groundwater from the Lower Eastern View Formation (LEVF) in the Jan Juc Groundwater Management Area and contains seven production bores that are licensed to extract a maximum of 40 ML/d, or 10,000 ML in any year, and 35,000 ML in any 5-year period. Five of the seven bores (GW1, GW 2, GW3, GW4 and GW5) are located proximal to the mine (**Figure 2-2**).

Commissioning and testing of the borefield first commenced in October 2009 and ceased in June 2012, with a total of 7,617 ML pumped during that period. Due to low water storage levels, recommissioning of the borefield began in August 2019 to supplement the existing Greater Geelong water supply system. Between August 2019 and end of June 2020 a total of 2,177.3 ML was extracted from the Anglesea Borefield.

The Anglesea borefield was moved into a standby maintenance mode from 1 July 2020 and has only been operated for maintenance purposes until January 27, 2022 when Barwon Water began their 6 - month groundwater pumping test to inform a review of its bulk entitlement and environmental monitoring program.

A timeline of historical extraction for both the UEVF and LEVF is presented in **Figure 2-5**.

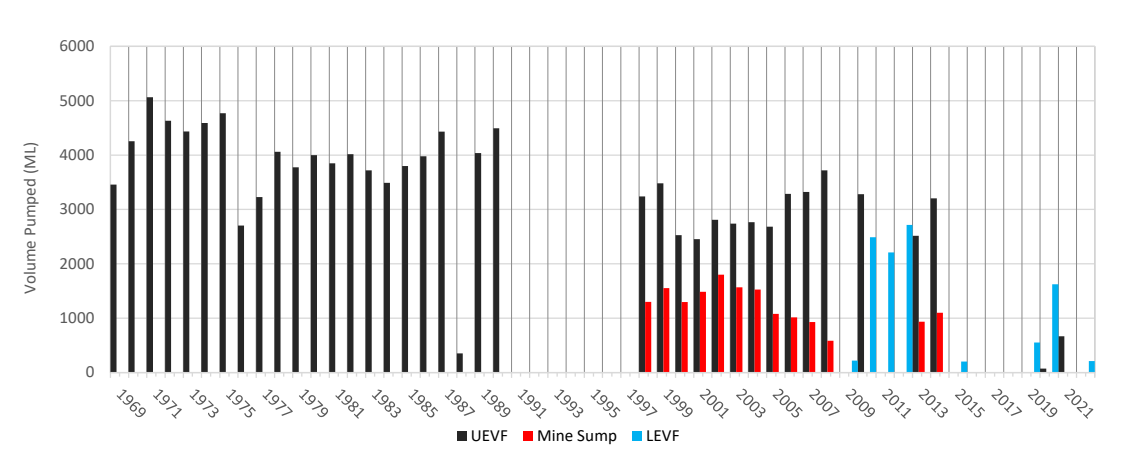

Figure Notes:

UEVF Data missing for 1991-1997, 2009 & 2011-2012
UEVF volumes prior to 1989 also include the mine sump volume
LEVF 2021 Data – Up to and including February 2022

Figure 2-5 Timeline of Historical Groundwater Extraction (UEVF, Mine Sump and LEVF)

2.3 Mine Rehabilitation Since 2015

Following the shutdown of the Anglesea Power Station and Mine in August 2015, detailed planning for the final closure and rehabilitation of the mine commenced including detailed technical studies and community and regulator engagement. In 2016 Guiding Principals were published after extensive consultation with the community, with these then used as an input into the development of the closure plan.

In September 2017 a draft Mine Closure and Rehabilitation Plan (MCRP) was submitted to Earth Resources Regulation (ERR) proposing earthworks, revegetation and the establishment of a water body. Subsequent to this, in March 2018 a Work Plan Variation – Progressive Rehabilitation was approved by ERR approving the earthworks and revegetation works.

Major earthworks were commenced in November 2018 and completed in June 2020, including the reprofiling of the west and south slopes of the mine, the installation of surface water catchment drains at strategic points around the mine, and the relocation of part of Coalmine Road.

Revegetation works consisted of native heathy topsoil revegetation works in 2018 and 2019 on the north and west walls, and also the establishment of a large native grassland on the south wall which was completed in September 2020. Both the earthworks and revegetation works have entered a monitor and maintain phase with active monitoring programs in place.

2.3.1 Installation of Groundwater Monitoring Bores (2020 / 2021)

Within the catchment there exists over 110 dedicated groundwater monitoring bores belonging to either Alcoa (71 bores), Barwon Water (32 bores) and the State Government SOBN (14 bores). These bores are shown in **Figure 2-2**. Many of these bores have been installed for a variety of reasons. These reasons (i.e. their purpose) along with basic construction details is presented **Appendix E**

During 2020 and 2021, 16 groundwater observation bores were constructed around the periphery of the mine. These are in addition to the 71 bores listed above. The location of these bores are shown in **Figure 2-7**. The rational for the construction depth and location of these bores is discussed in **Table 2-1**. Their construction details is presented **Appendix E** and bore logs presented in **Appendix F.**

Table 2-1 Rationale for Construction of New Near Mine Void Bores

Bore ID	Targeted Lithology	Rationale
UEVF MB 1	The upper sands of the UEVF, refer **Section 5.2.2.2.3**	The purpose for construction of these bores is to: • Obtain a greater understanding of the lithology and water levels in the upper section of the UEVF. • Confirm extensiveness of the basal clay which is assumed to overlie and confine theses “upper sands”. • To act as monitoring bores to monitor for potential drawdown impacts arising from the pumping test which could then imply drawdown from the mine pit waterbody into formation.

DBG MB 9		

2.3.2 Catchment Drains

Important to the overall mine water balance are the installation of catchment drains to assist surface water runoff from the greater mine lease area to be directed into the mine void. Some of these drains are pictured on **Photo 1** and the overall layout of the drains and their supporting catchment is shown in **Figure 2-6**. The estimated volume of runoff these drains are likely to provide is discussed in **Section 5.6**.

2.3.3 Subsidence Monitoring

From 1996 until current subsidence has been monitored from prism and GPS pin monitoring from the south wall area of the mine (**Appendix I**). In summary, the movement that is observed during the 2000's is attributed specially to 'relaxation' of the wall in response to actual mining. Apart from this, RL's typically have not moved significantly since monitoring began.

2.3.4 Decommissioning of Site Infrastructure

Between 1969 and 2015, Alcoa's groundwater extraction and monitoring used a series 12 groundwater bores (WB3-5, WB8-10, and WB12-17) located across the former Power Station site. During 2020 and 2021 these bores were subject to a borehole assessment program (BAP) which comprised geophysical logging (gamma and calliper) and downhole camera inspection to determine the bores condition and the reliability of the data during the pumping test. The results of the BAP are presented in **Table 2-2**.

Table 2-2 Findings of Bore Assessment Program

Bore ID	Bore Construction Log available	Pump in bore	Screened intervals (mbgs)	Obstructions (mbgs)	BAP Assessment
WB3	No	No	No bore construction log available and screen intervals could not be confirmed with CCTV	126m Unknown blockage	During the CCTV investigation the bore was confirmed to be full of sediment. The bore was cleaned out using mud rotary drilling techniques to a depth of 201 m, which is either the base of the bore or an obstruction. The drill rig could not progress past this depth. The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF, therefore it was decommissioned. The bore was perforated at a depth of 195 m, approximately 5 m above the UEVF/MEVF interface.
WB4	No	No	Bore was re-sleaved	84.1 - Bore has been bridged, a lot of sediment sitting on top of the bridge	In 1977, this bore was repaired by re-sleaving with an 8-inch casing. As part of the BAP, the drilling contractor advanced down through the bore annulus to 195m. A geophysics survey was completed and the screened intervals were confirmed at 117-120 m, 161-164m, 176-182m. It is likely that other screened intervals were installed but these could not be confirmed by the geophysics survey. A decision was made to re-sleave WB4. The re-drilling of the bore as part of the BAP was successful and lithological information and geophysical logs were reviewed to enable a suitable design. The following bore design summary is provided: • 50mm diameter screen and casing • Screen intervals at 117-120m, 161-164m, 176-182m, 191-194m. The casing was perforated at 192.5m • Fibre-glass casing was used from 0-117m • Stainless steel screens and blank casing were used from 117-195m • A sump was installed from 194-195m.

Bore ID	Bore Construction Log available	Pump in bore	Screened intervals (mbgs)	Obstructions (mbgs)	BAP Assessment
WB5	No	No	110.3 - 112.5 Additional screened intervals not encountered due to obstruction	112.5 - Appears to be cabling associated with a pump	Downhole camera confirmed that the casing had pulled apart at 86.5 m and the bore was full of sediment to 112.5m. The bore was cleaned out using mud rotary drilling techniques to attempt to reach the bottom of the bore and to confirm screen intervals. Based on the drillers observations, and the geophysics survey responses, the casing was compromised at a number of depths and therefore WB5 was confirmed to be unsuitable for monitoring or sampling purposes. The responses also indicated that the bore was only constructed to a shallow depth, around 151 m, when compared to the surrounding production bores. Therefore this bore was only screened in the lower sands of the UEVF and was decommissioned appropriately.
WB8	No	No	No bore construction log available and screen intervals could not be confirmed with CCTV	47.5 - Appears to be rusted metal	The driller confirmed that this bore had previously been decommissioned and grout was encountered at 50 m when cleaning out the bore. This bore was then decommissioned again using a grout/bentonite mix to the ground surface.
WB9	Yes	No	126.2 - 129.2 146 - 149 155 - 161 172 - 175 181.1 - 182.6 Obstruction at 188.1	188.1	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, therefore it was decommissioned. The bore was perforated at a depth of 162 m.

Bore ID	Bore Construction Log available	Pump in bore	Screened intervals (mbgs)	Obstructions (mbgs)	BAP Assessment
WB10	Yes	Yes	109.1 - 112.1 124.1 - 127.1 131.0 - 133.5 138.6 - 141.6 159.5 - 161.1 172.9 - 174.4 187.5 - 191.8 197.8 - 199.3 207.8 - 211.4	None	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, therefore it was decommissioned. The bore was perforated at a depth of 117 m.
WB12	Yes	No	147.2 – 157.0 174.3 – 178.9 184.4 – 187.5 200.3 – 205.1 219.8 – 221.3	108.1 - Unknown 151 - Obstruction identified during second CCTV camera 194 - Driller pushed obstruction to depth	As part of the BAP, the drilling contractor has identified a number of integrity issues with this bore: • Collapsed casing at 90m; • Damage to the casing (large holes) between 107m and 117m. • Significant debris throughout with a large obstruction at 193m. • Screens blocked by silt / sediment and likely iron bacteria. At this stage WB12 forms part of the monitoring network. Following pump shut down and the collection of recovery data, further analysis will be undertaken to assess the response in WB12. Depending on the outcomes of the data analysis, WB12 may be: • Rectified by re-sleaving the casing issues, removing the obstruction at depth and cleaning the screened intervals; or • Decommissioned. Note any decommissioning will not be undertaken whilst the pump test is active.

Bore ID	Bore Construction Log available	Pump in bore	Screened intervals (mbgs)	Obstructions (mbgs)	BAP Assessment
WB13	Yes	Yes	165.05 – 168.25 175.25 – 178.45 187.0 – 190.2 199.05 – 200.71 213.44 – 216.62 227.59 – 232.29	145 - Appears to be lines/chords. They were removed	The geophysics data confirmed that this bore was likely cross-screening the UEVF and MEVF/LEVF, therefore it was decommissioned. The bore was perforated at a depth of 160 m.
WB14	Yes	Yes	155.9 – 158.9 183.0 – 168.5 183.0 – 183.0 187.4 – 190.4 194.8 – 196.8 211.7 – 213.7	138.7 - Appears to be a metallic object and cabling	Obstruction removed and bottom of bore confirmed at 214 m. Geophysics data confirmed that this bore is screened within the UEVF. The bore was found to be in good working order.
WB15	Yes	Yes	186.8 – 190.8 197.8 – 200.8 210.8 – 214.8 220.4 – 222.4 227.0 - 230.0 244.5 – 247.5	79.0 - Potentially pump cabling. Obstruction removed 4 September 2020	Obstruction removed and bottom of bore confirmed at 225 m. Geophysics data confirmed that this bore is screened within the UEVF. The bore was found to be in good working order.

Bore ID	Bore Construction Log available	Pump in bore	Screened intervals (mbgs)	Obstructions (mbgs)	BAP Assessment
WB16	Yes	No	173.7 - 177.7 183.7 - 189.7 199.2 - 203.2 208.3 - 211.3 216.8 - 220.3	None	WB16 is the pumping bore. Prior to undertaking the plumping test, the bore was inspected by downhole geophysics and CCTV camera. The bore was found to be in good working order.
WB17	Yes	Yes	120.6 – 127 133 – 137.2 144.2 – 147.2 155.2 – 158.2 169.2-174.2 178.2 – 182.4 185.6 – 189.6	171 - Not confirmed	Obstruction pushed down to 177 m. The geophysics data confirmed that this bore was cross-screening the UEVF and MEVF, therefore the bore was perforated at a depth of 167 m and it was decommissioned.

2.4 Summary of Lessons Learnt from Post 2015 MRCP Activities

The following lesson learnt presents information that either confirms or suggests material departures from hydrogeological assumptions and conclusion derived from pre 2015 investigations. A high-level summary of these learnings is presented in the sections below. All learnings have been used to inform the development of the updated conceptual hydrogeological understandings (summarised in **Section 6**) as well as the draft Anglesea Numerical Model (GHD 2022 Draft).

2.4.1 Learnings from Installation of New Observation Bores

As shown in **Figure 2-7,** 8 nested pairs of bores have been installed in to the shallow DBG and the upper sands of the UEVF around the periphery of the mine. Geological core has been retained from several bores (UEVF MB 7 and UEVF MB 8) and 5 core sections within UEVF MB 7 were subject to laboratory permeability tests. Key learnings are presented below.

- The majority of the DBG bores are dry indicating that near the mine void, these units discharge water into the mine void keeping the local DBG unsaturated.

  This observation matches previous conceptualization and assumptions.

- In bore log UEVF MB08 on the western margin of the mine, the UEVF Upper Sands were not encountered. Numerous other exploration bores in this location also identified no sand units below the main coal seam. This suggests the upper sands of the UEVF form a discontinuous permeable unit and are primarily found underneath the basal clay in the vicinity of the former mine and potentially extend towards the coast. The upper sands do not outcrop or extend in any great distance west and north of the mine, rather they pinch out within the subsurface.

  This observation is a departure from earlier assumptions where these upper sands were assumed to be regionally extensive.

- A clay unit (basal clay) exists below main coal seam however may have been excavated near the vicinity of the mine sump and at UEVF MB 6. At these locations the mining of coal may have thinned the basal clay to a minimal thickness causing some degree of connectivity to the UEVF upper sand lens and the mine water body. Further evidence of this is groundwater elevations from data loggers installed in Bores UEVF MB01-07 show increasing trends. This could be in response to cessation of the sump pump which was historically operated to keep the sump dry. Groundwater contours shown on **Figure 5-59** also show that groundwater is migrating to the sump location. Water quality is also variable across these upper sand locations however no spatial correlations can be concluded. For example, the water quality in UEVF MB07 ranges 170 to 200 mg/L TDS which is significantly fresher than all surface water systems and other UEVF MB bores. This suggests that this sand lens is recharged where the sand outcrops and is not influenced by the alluvial swamp aquifer (ASA) or surface water. Interestingly, the hydrographic response in this bore shows no evidence of delayed recharge to rainfall and has similar trends to the other UEVF Upper sand bores.

  This is a departure from earlier assumptions where it was assumed the basal clay underlie the main coal seam and varied in thickness between 1-4m.

- Laboratory permeability tests of clay and coal sections within UEVF MB 7 indicate that permeability ranges from 7E-10 m/sec at 33mbgl to 3E-9m/sec at 55mbgl to 2E-9m/sec at 70.5mbgl and 1E-10 m/sec at 140mbgl.

  This is a minor departure from earlier assumptions. Whilst it was assumed these coal and clay lenses were relatively impermeable, these permeabilities are 1-2 orders of magnitude lower that initially conceptualized.

- A total cumulative thickness of over 100m of low permeability clay and coal sequences separate the upper sands and lower sands of the UEVF.

  This is a departure of past conceptualisations where the total thickness of the UEVF was treated as a bulk aquifer (with an even distribution of sand, clay and coal seams distributed throughout its thickness).

2.4.2 Learnings from the 6-Month Pumping Test

A 6-Month groundwater pumping test commenced on 13 May 2021 and ceased on 8 December 2021. The objective of the pumping test was to establish various aquifer parameters to support a revision to the Anglesea Groundwater Model (Refer GHD 2022) and determine additional information to support a potential licence amendment for the UEVF.

A total of 671.9ML was extracted during the test and monthly reviews were conducted with the Co-regulator Technical Working Group (inclusive of Alcoa, Southern Rural Water, DELWP, EPA Victoria, Earth Resources Regulation, Barwon Water and Corangamite Catchment Management Authority).

Appendix D presents the in-depth findings from the Pumping test however the following observations can be made:

- Prior to the pumping test being undertaken, analytical solutions indicated that at a pumping rate of 50 L/sec, drawdown impacts >0.2m after 6 months would radially extend ~3km from the dewatering bore. During the test, SOB 116459 which is located 2,986m from WB16 appeared to show a minor impact on the groundwater trend (0.2m over 3 months) once the pumping rate was increased from 40 L/sec to 50 L/sec. Once the pumping rate was reduced to 40 L/sec, groundwater levels within this bore stabilized, refer **Figure 5-61**.

  This observation matches previous assumptions and indicates that the preliminary hydrogeological parameters and assumptions used in the initial setup on the analytical model (and earlier numerical models) are reasonable. Furthermore, the relative instantaneous response of groundwater levels to changes in the pumping rate at this distance indicate that the lower sands of the UEVF are consistent with low storativity. Again, previous assumption of low aquifer storativity are supported by this observation.

- As discussed in **Section 2.4.1** the upper half of the UEVF contains predominantly thick sequences of low permeability clay and coal.

  This understanding is a departure of past conceptualisations where the total thickness of the UEVF was treated as a bulk aquifer (with an even distribution of sand, clay and coal seams distributed throughout its thickness). In addition to the drilling and geophysical logging of observation and production bores, during the pumping test, groundwater pressure in all monitoring bores in the mid and upper section of the UEVF within close

proximity to the pumping bore demonstrated no impact from pumping. The lower section of the UEVF where the pumping well was screened exhibited drawdowns up to 65m.

2.4.3 Other Learnings

Other learnings that can be noted are:

- Near the mine void, a low permeability clay separating the water within the ASA and underlying groundwater systems is mapped in all bores/exploration holes that are/were located in the ASA. Episodic or delayed responses to rainfall are not observed in the UEVF upper sands indicating leakage is minimal. The water table within the ASA at WTOB2 remains relatively stable with declines only observed in dry summers, refer **Figure 5-72**.

  This observation matches previous conceptualization and assumptions whereby the ASA is considered to behave like a perched system with assumed limited connectivity to underlying aquifer systems, having an aquitard (low permeable layer) separating the water within the ASA and underlying groundwater systems.

- Permeability tests from 29 sites located in the mine void representative of the reworked and backfilled BDG at depth between 0.5m and 8m show Kv (min = 6.9E-6m/d, max = 6.05E-3 and mean = 8.6E-5m/d). Further information on these results is presented in EHS Support 2022a (Draft).

  This is somewhat of a departure from initial assumptions. Whilst the DBG was considered to consist of low to moderate permeability, these permeabilities are several orders of magnitude lower that initially conceptualized. The long lasting pooling of water after rainfall on the DBG, refer Section 5.4.2.3 and Figure 5-49 is also an indication of the formations low infiltration potential.

- Since the decommissioning of several older Alcoa production bores which may have cross screened UEVF and MEVF/LEVF formations (refer **Section 2.3.4**), recent groundwater level data post bore decommissioning show no response from LEVF pumping in the UEVF lower sands, refer to **Figure 2-8**. Prior to bore decommissioning when the LEVF was pumped from GW1-5, minor impacts on the UEVF were observed in the UEVF (refer Bore WB5 response). Post decommissioning, these impacts are not replicated.

  This is somewhat of a departure from initial assumptions the Middle Eastern View Formation (MEVF) was thought to be a leaky aquitard due to the minor drawdown impact in UEVF bores during historical LEVF pumping. Whilst is it likely that the MEVF contains areas where it is leakier that others, it is likely that in the Alcoa AOI, the MEVF is potentially tighter than initially conceptualised.

- A review of all available exploration geological bore logs (22 logs) that were located either within or adjacent to the ASA shows that an average thickness of 27.7m (max = 86m; min = 2.4m) of either clay or silt (e.g. low permeability material) that separates the base of the alluvial / swamp sediments in which surface water flows to the next most permeable layer underlying the surface water systems.

  This observation matches previous conceptualization and assumptions that the swamps and marshlands that make up the ASA act like a Perched Water Table (PWT).

- A review of all ASA monitoring bores have shown a stable trend over the last 10 years with despite Alcoa extraction up to 2016 and more recent aquifer tests, and also aquifer tests undertaken by Barwon Water between 2009 and 2012 and again recently in 2022.

  This observation matches previous conceptualization and assumptions that the swamps and marshlands that make up the ASA act like a Perched Water Table (PWT).

- A review of the impact of episodic rainfall events on groundwater levels within the ASA and underlying BDG and UEVF show that for most large rainfall events exceeding 40mm, an immediate increase in groundwater levels at most ASA monitoring locations was observed. For nested sites or where bores are close together, for the corresponding rainfall event no increase or only very minor and delayed responses was observed in underlying BDG or UEVF monitoring points. This indicates that direct rainfall recharge is the dominant driver of recharge to the ASA.

  This observation matches previous conceptualization and assumptions that the swamps and marshlands that make up the ASA act like a Perched Water Table (PWT).

- Within the ASA, the steepest decline of groundwater levels occurs over spring and summer when episodic rainfall events are absent (such as spring and summer of 2011/12; 2013/14; 2015/16; and 2019/2020). This similar correlation is not commonly observed in unconfined aquifers surrounding the ASA such as the outcropping UEVF and BF.

  This observation matches previous conceptualization and assumptions that evapotranspiration (during dry spring and summers) is a key cause of water loss from the ASA.

- It is estimated that allowing the mine pit void to naturally fill would take between 50 and 100 years.

  This estimation will be impacted by the installation of catchment drains (may fill quicker) to assist surface water runoff from the greater mine lease area to be directed into the mine void, Figure 2-6. However, under certain climate change scenarios, this time frame could take longer.

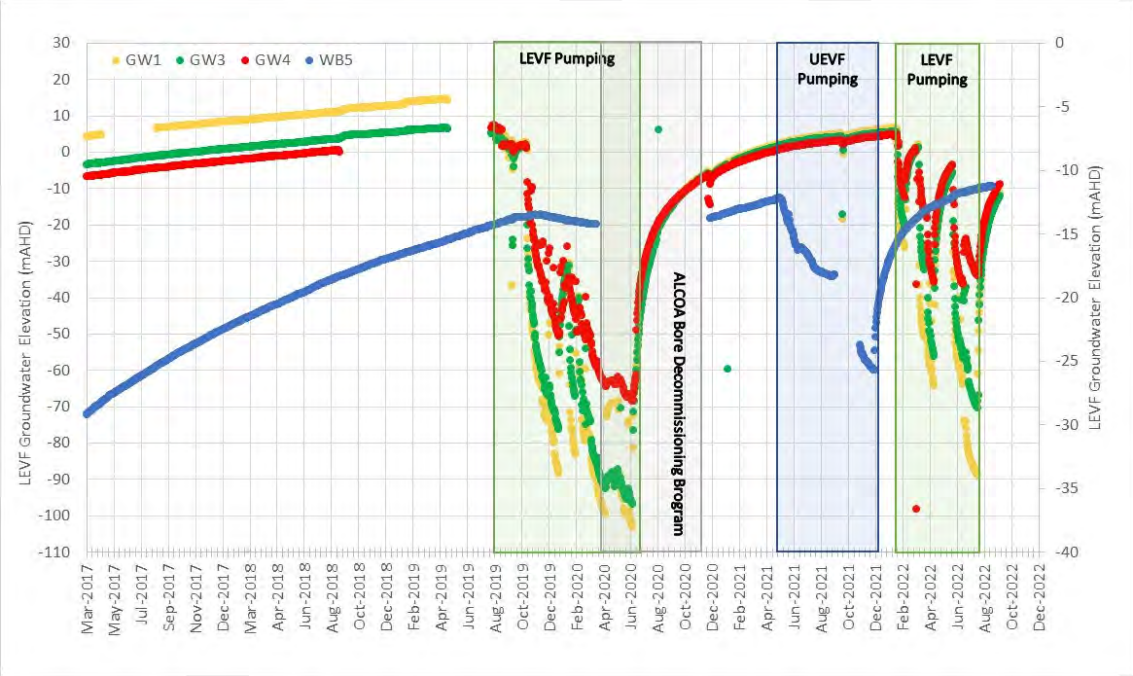

Figure 2-8 Groundwater Elevations Before and After the Assessment Program

2.5 Summary of Groundwater Investigations

As discussed in **Section 1.1** data presented within this report is not intended to cover the whole catchment as Alcoa's area of interest (AOI, refer **Section 5.2.1**) only cover a small part of the overall catchment. There has however been a plethora of existing environmental investigations and impact assessments undertaken over the last 60 years to characterise groundwater behaviour both within Alcoa's AOI and more broadly across the greater catchment and groundwater management area. The main investigations that have significantly advanced the understanding of the hydrogeological conditions are summarised in **Table 2-3**. These reports and data, where available, have been used to assist in building this conceptual hydrogeological model (CHM) and the development of the original numerical groundwater (GHD 2013) flow model used to assess groundwater extraction-related risks.

The detailed findings (such as aquifer permeability data) where necessary from each of these investigations are summarised within **Section 5** (Conceptual Geological and Hydrogeological Model).

2.6 Summary of Surface Water and Catchment Investigations

In addition to groundwater data, numerous investigations have been conducted detailing surface water and catchment conditions. Those considered as key references in assisting the understanding of environmental conditions surrounding the mine (as well as in the broader catchment) are presented in **Table 2-4**.

In addition to the studies listed in **Table 2-4**, a number of research projects were completed on the surface water chemistry in the Anglesea catchment including, 'The cause(s) of the acidification of the Anglesea River, Victoria' (Hermon, 2002), and 'Trace element distribution and speciation in the Anglesea River' (Meyrick, 1999). Both investigations focused on aluminium (Al), iron (Fe), manganese (Mn) and zinc (Zn) concentrations, and Hermon (2002) focused especially on pH values. Hermon (2002) concluded that an acid sulfate mechanism is naturally operating within the Anglesea catchment. This conclusion has been supported by numerous other investigations (Maher, 2011 and GHD, 2013a).

The geology of the area has been extensively investigated. Recent research includes, 'Geology of coal bearing Palaeogene Sediments, Onshore Torquay Basin, Victoria' (Holdgate, *et al.,* 2001) and 'Local Geology and the Eastern View Coal Measures, Anglesea, Victoria' (Smith, 1998).

Table 2-3 Key References Used to Develop the CHM

Report	Description	Relevance to Alcoa's AOI
The Hydrogeology of the Anglesea Area (Hancock, 1967)	This report presents an early discussion of the hydrogeology and geomorphology of the Anglesea region. The initial findings of site conditions are also discussed and provided valuable insight to the hydrogeological conditions pre mining.	Directly relevant to Alcoa's AOI
The Impact of Groundwater pumping at the Alcoa Coal Mine at Anglesea on Regional Aquifers (SKM, 1998)	This report presents groundwater monitoring information and other hydrogeological information relevant to Alcoa pumping and its potential effects on the surrounding area.	Directly relevant to Alcoa's AOI
Groundwater Extraction Assessment (SKM, 2007)	The purpose of this study was to provide further preliminary results for the impacts assessment and identify areas for further investigations. The scope of work involved the following tasks: • Develop a strategy for liaison with SRW and Department of Sustainability and Environment (DSE); • Obtain available information from Alcoa and the Department of Primary Industries (DPI); • Undertake a detailed hydrogeological assessment to develop a conceptual model; • Formulate and calibrate a three-dimensional finite difference numerical model using MODFLOW 2000 to predict the groundwater response to future changes in mine dewatering; • Develop a two-dimensional finite element FEFLOW model to assess the movement of salt water near the coast under additional pumping stresses; and • Make recommendations for areas requiring additional hydrogeological information.	Directly relevant to Alcoa's AOI
Holdgate (2001, 2002 and 2009)	These reports contain a stratigraphic evolution of the Boonah Formation and how this unit was re-assigned from the Eastern View Formation (EVF) to the DBF.	Directly relevant to Alcoa's AOI
Anglesea / Barwon Water Bore Field Project (GHD, 2008, 2013)	This report presents numerical modelling simulations and hydrogeological conceptualisation associated with the Barwon Water Bulk Entitlement from the Victorian Government in 2009 to install and operate the 7,000 ML/year (19.2 ML/day) borefield. The later report (2013) provides updates to the conceptual hydrogeological model as well as numerical model.	Alcoa's AOI plus the broader catchment

Report	Description	Relevance to Alcoa's AOI
Anglesea Borefield Project Isotopic and Tracer Studies (GHD, 2011a)	This report details the scope, methodology and results of detailed environmental tracer and groundwater dating studies conducted in the Anglesea Borefield project area. The key objectives of the environmental tracer and dating studies were to: • Provide a better understanding of potential interactions between groundwater and surface water in key asset point areas (located within what are referred to as the Northern and Southern Lower Eastern View Formation [LEVF] Outcrop Areas); and • Provide a better understanding of groundwater residence times, and therefore allowing better numerical model conceptualisation and calibration.	Alcoa's AOI plus the broader catchment
Anglesea Borefield Surface Water Quality Results (GHD, 2011c to 2016 and 2019).t	These reports detail the results of the annual Surface Water Quality monitoring requirements as listed under the Barwon Waters Bulk Entitlement and associated Monitoring and Assessment Program (MAP). Note: Only raw data from 2019 has been sighted and used in this report.	Alcoa's AOI plus the broader catchment
Jan Juc Groundwater Management Area Groundwater Resource Appraisal (GHD, 2019)	This report was commissioned by DELWP with the scope to complete a review of the Sustainable Yield of the Upper Eastern View Formation (UEVF) aquifer within the Jan Juc Groundwater Management Area (GMA).	Alcoa's AOI plus the broader catchment
Groundwater Monitoring Reports (Coffey, 2006 to 2015)	This series of reports presents groundwater monitoring works at the former power station to assess potential groundwater impacts, and if so, compare groundwater results to ecological and health-based investigation levels, and assess the potential impact to receptors based on the groundwater quality.	Directly relevant to Alcoa's AOI
7-Day Constant Rate Pumping Test (EHS Support, 2020)	EHS Support completed a pumping test investigation, including a step drawdown test and 7-day constant rate pumping test, to refine aquifer hydraulic parameters of the UEVF.	Directly relevant to Alcoa's AOI

Report	Description	Relevance to Alcoa's AOI
6-month UEVF Pumping Test (**Appendix D** of this report)	A long-term pumping test was undertaken on the UEVF Lower Sands aquifer (13 May 2021 to 8 December 2021) with the following objectives: • Obtain additional hydrogeological data (such as storativity and transmissivity) that can be used to develop a robust and peer-reviewed conceptual and numerical groundwater flow model that will determine if the use of longer term UEVF groundwater is a practical and an environmentally sustainable water management strategy to fill the mine pit void as part of the MRCP. • Address data gaps identified in the draft MRCP.	Directly relevant to Alcoa's AOI

Table 2-4 Key References Used to Develop an Understanding of Catchment Conditions

Report	Description	Relevance to Alcoa's AOI
A Hydrogeochemical Assessment of Trace Element Concentrations at the Alcoa Power Station (Beattie, 2003)	This report was for the fulfilment of an honours degree and contained an environmental assessment of the site. The assessment included a lithology, hydrology and geochemical evaluation of trace element concentrations in the shallow aquifer.	Directly relevant to Alcoa's AOI
Anglesea Borefield Project Groundwater Investigations: Terrestrial Flora and Fauna (Ecology Australia, 2007)	This is a report conducted for Barwon Water and presents an investigation of the potential dewatering impacts on terrestrial flora and fauna arising from the proposed Barwon Water Bulk Entitlement groundwater extraction.	Alcoa's AOI plus the broader catchment

Report	Description	Relevance to Alcoa's AOI
Anglesea Borefield Flora and Fauna Monitoring (Ecology Australia 2008 - 2013)	These reports present extensive flora, fauna and aquatic ecological surveys that were undertaken in the study area to identify significant species and establish baseline conditions as part Barwon Waters Bulk Entitlement impact assessment.	Alcoa's AOI plus the broader catchment
Anglesea River Water Quality Review. Independent Review (Maher, 2011)	This report was undertaken in response to growing community concerns about the health of the Anglesea River. This report deals with the request in April 2011 from the Minister for Environment and Climate Change, to conduct an independent investigation with the following terms of reference: • Review the history of acid events in the Anglesea estuary. • Identify the sources of acidic water and metals in the estuary. • Investigate the role of specific factors that are of concern to the community, such as, the role of land use in the catchment, licensed discharge into the river and water extraction. • Review options for remediation of poor-quality water originating from the catchment.	Alcoa's AOI plus the broader catchment
Barwon Water – Report for Anglesea Borefield Project (June, 2011)	This assessment evaluated the degree of groundwater surface water interaction at the Salt Creek and Anglesea River pools. Initial numerical modelling indicated that the upper reaches of the Anglesea River and Salt Creek may be baseflow dependent.	Alcoa's AOI plus the broader catchment
Anglesea Power Station 53V Audit (GHD, 2012)	This report was triggered by the issuing of a Pollution Abatement Notice (PAN) after high levels of boron were discovered downstream of the former power station.	Directly relevant to Alcoa's AOI
Anglesea River Estuary Flow Assessment Final Approved Report (GHD, 2016)	The Anglesea River Estuary Flow Report Assessment provides an assessment of the changes to the physical character and ecological, social and economic values resulting from changes to the mine and power station discharge, and a high-level scoping of options to manage the predicted changes.	Alcoa's AOI plus the broader catchment
Anglesea Estuary Water Balance Scenarios (GHD, 2017)	Anglesea River scenario modelling to understand the effect of Salt Creek diversion on maintaining the minimum stage height requirements and flows for the maintenance of beneficial uses in the Anglesea River estuary.	Alcoa's AOI plus the broader catchment

Report	Description	Relevance to Alcoa's AOI
Anglesea River and Estuary Environmental Flow Study (GHD, 2021)	The study aimed to determine the environmental flow requirements for waterways in the catchment and estuary of the Anglesea River. This study involved field assessments and developing water balance, hydrodynamic and geochemical models. This report also quantifies the catchment groundwater dependence ecosystems	Alcoa's AOI plus the broader catchment
Anglesea Borefield Bulk Entitlement Aquatic Monitoring (GHD, 2011b to 2016)	These reports detail the results of the annual aquatic ecological monitoring requirements as listed under the Barwon Waters Bulk Entitlement and associated Monitoring and Assessment Program (MAP)	Alcoa's AOI plus the broader catchment
Anglesea Acid Sulfate Soil Assessment (Wong et al. and Monash University, 2021)	A study carried out on behalf of Monash University to better understand Acidity in the Anglesea River catchment	Alcoa's AOI plus the broader catchment
Anglesea Borefield Surface Water Quality Results (GHD, 2011c to 2016 and 2019).t	These reports detail the results of the annual Surface Water Quality monitoring requirements as listed under the Barwon Waters Bulk Entitlement and associated MAP.	Alcoa's AOI plus the broader catchment

Report	Description	Relevance to Alcoa's AOI
Review of Numerical Model Outputs and Assessment of the Implications on Potential Acid Generation Process (GHD, 2013a)	The scope of this assessment is limited to a review of previous documentation, the findings of the updated numerical modelling report and monitoring data collected as part of ongoing MAP established for the Bulk Entitlement (BE). The scope of works comprised of the following tasks: • Review of background information (including GHD, 2012b) and develop simple conceptual models for key components of the catchment where there may be a potential for further acid generation to occur; • Review the updated hydrological model report (GHD, 2013b), particularly relating to effects of pumping on drawdowns and cease to flow events and provide an opinion on whether the acid generation potential is likely to be increased due to Barwon Water extraction (for both climate scenarios); • Review the significant first flush predictions to assess whether significant first flush events that may affect the Anglesea Estuary are likely to change frequency during BW extraction in comparison to baseline conditions; • Develop threat descriptor tables for potential acid generation and assign threat scores to different areas of the catchment, as part of the Ecological Risk Assessment process being undertaken as part of evaluating impacts from groundwater extraction; and • Complete a short report (this document) detailing conceptual models, assumptions, the reasoning behind threat descriptors and threat scores and conclusions on whether there is likely to be a potential impact on acid generation in the Anglesea catchments under BW pumping, under the different median and dry climate model scenarios.	Alcoa's AOI plus the broader catchment

2.7 Data Sets

2.7.1 Surface water

2.7.1.1 Flow

Total stream flow data available at monitoring point SV2 (Lower Salt Creek) ranges from 1967 to 1982 and 2009 to current. Flow records at monitoring point AV2 (Marshy Creek) ranges from 2009 to current. At SV2, flow data recorded since 2009 shows that there has been significantly less flow in Salt Creek when compared to the 1967 to 1982 time period. Due to the vastly different flow and climatic conditions in each period and the 27-year data gap between each period, there is uncertainty to apportion the cause(s) of the recent flow decline. However, evidence suggest the decline correlates well to climate. This is discussed further in **Section 3.3** and **Section 3.8**.

Temporal rainfall and runoff flow gauge data is insufficient to determine the rainfall-based flow for high and medium frequency events (greater than 1 in 50-year event). Estimates extrapolated beyond that are considered unreliable and cannot be established using the accepted flood frequency analysis techniques. As such, a runoff routing model (RORB) for Salt Creek was developed to allow reliable estimation of rare and extreme events. RORB is a runoff and streamflow routing program that is used to calculate flood hydrographs. The model uses available rainfall records in the catchment, estimates losses and calculates runoff.

In most cases since 2012, Barwon Water have monitored stage heights at locations further up the catchment. There locations (**Figure 4-2**) are AV1, SV1, AV3, SV3, AV4 and SV4 (all V-notch weirs); AGP1-A, AGP1- B, SGP1-A, SGP2-A, SGP1-B (all permanent water holes) and ASP7 and AGP2 (wetlands).

2.7.1.2 Water Quality

Due to ythe ephemeral nature of the of Salt Creek, a limited data set of comprehensive water quality parameters exist. Additional monitoring has been completed and will continue at varying stages of future flows (pre-during and post peak) to assist with further characterisation of the surface water beyond that of major ions and physio-chemical parameters.

While water quality data was collected from the mine pit void prior to 2016, there remains uncertainty around how and where these mine pit void samples were taken.

As above, Barwon Water have monitored (usually quarterly), water quality at locations AV1, SV1, AV3, SV3, AV4 and SV4 (all V-notch weirs); AGP1-A, AGP1-B, SGP1-A, SGP2-A, SGP1-B (all permanent water holes) and ASP7 and AGP2 (wetlands). **Figure 4-2** shows monitoring locations. This data is also summarised in annual groundwater quality for the Barwon Waters Anglesea Borefield project (refer GHD 2017 for latest summary).

2.7.2 Groundwater

2.7.2.1 Hydro-Stratigraphy

The region around the coal mine contains detailed information that has allowed for a comprehensive understanding of the sub-surface stratigraphy. Furthermore, the hydraulic behaviour/parameters of each major aquifer (LEVF and UEVF) are generally well understood. Whilst the hydraulic properties of the Middle Eastern View Formation (MEVF) aquitard are unknown, concurrent aquifer pumping have occurred in bores screened above and below the MEVF. This has enabled some estimation on its competence as an aquitard. Furthermore, during the installation of the Anglesea borefield, core was obtained of the shale and siltstone of the MEVF.

2.7.2.2 Groundwater Level

Groundwater level data has been collected across the catchment with some groundwater levels dating back to 1969. **Appendix E** provides a summary of the amount of groundwater data that has been collected over time as well as a brief comment on the data reliability.

2.7.2.3 Groundwater Quality

Across the mine and power station site, groundwater quality sampling has been sporadic and governed by individual project timelines. Physio-chemical parameters such as pH and total dissolved solids (TDS) have been sampled relatively frequently, with some datasets extending back to 1970.

Transient groundwater quality defined by analytical suites containing organics, nutrients, metals and major and minor ions are limited; however, through the development of Barwon Waters Anglesea borefield and sporadic sampling of Alcoa's observation bores, sufficient water quality data exist to classify water types and perform data analysis involving geochemical mixing.

As above, Barwon Water have monitored (usually quarterly), water quality at locations of bores listed in **Appendix E** that form part of their Anglesea forefield monitor network.

2.7.3 Climate

Six meteorological weather stations exist near the site with the closest weather stations to the site being Wensleydale, approximately 6 km to the northwest and Aireys Inlet, approximately 9 km to the southwest. The weather stations and the data considered in this study are presented in **Table 2-5**[1].

Table 2-5 Climate Data Summary

BOM Station Name	Station ID	Year From	Year To	Lat.	Long.	Temp	Wind Speed	Rainfall	Evap.
Aireys Inlet	90180	1994	2022	-38.458	144.0883	x	x	x	
Wensleydale Anglesea (Vehicle Proving Ground)	87119	1965	2020	-38.368	144.0843			x	
Torquay Golf Club	87160	1974	2016	-38.340	144.3101			x	

[1] All meteorological data is derived from www.bom.gov.au.

BOM Station Name	Station ID	Year From	Year To	Lat.	Long.	Temp	Wind Speed	Rainfall	Evap.
Wurdiboluc Reservoir	87126	1969	2016	-38.282	144.0518			x	x
Buckley (Balliwindi)	87124	1968	2022	-38.250	144.0854			x	
Boonah	90187	2001	2022	-38.411	143.9771			x	

The data listed in **Table 2-5** are considered appropriate for the required use with the exception of hydrodynamic modelling. For this activity site-specific climatic conditions of wind, temperature and solar radiation are required and is a consideration for the long-term MRCP.

3 Environmental Setting

3.1 Topography and Land use

The topography of the Anglesea area is presented in **Figure 3-1**. The land surface falls rapidly from 300 m AHD to 400 m AHD in the west to 0 m AHD along the coastal plains.

The topographically elevated areas to the west of Anglesea are dominated by forest. This primarily comprises native vegetation conservation areas, with smaller areas of production and plantation forestry (**Figure 3-1**). Across the flatter areas to the north and east, grazing pastures dominate. Urban land use is limited to small areas at the coastal towns. Several large and small marsh and wetland areas are found across the region. There are extensive swamp areas immediately northwest of Anglesea along the Anglesea River and Salt Creek (**Figure 3-1**).

3.2 Climate

The Anglesea area is characterised by relatively high rainfall in the topographically elevated areas to the west, with decreasing rainfall across the lower northern and eastern areas. The two closest rainfall gauges are located at Wensleydale (BOM ID 87119), approximately 6 km northwest of the mine (within Anglesea River Catchment), and Aireys Inlet (BOM ID 090180), approximately 9 km southeast of the mine along the coast.

Long-term average annual (LTA) rainfall at Wensleydale is 769 millimetres per year (mm/yr) based on data from 1935 to current. At Aireys Inlet, the LTA is 616 mm/yr based on data from 1994 to current. Yearly averages are presented on **Figure 3-2** along with rainfall surplus/deficit data from Wensleydale.

Since measurements began in 1965 at Wensleydale, rainfall data indicates a distinct wetting and drying phase. Using SILO Data Drill system[2] for the site, a longer-term record can also be derived beginning 1900, and this identifies a 3rd climatic phase, (**Figure 3-3**). This climate signature shows:

- Between 1900 and 1950, the region exhibited a drying climate, defined by average annual rainfall typically being lower that the LTA rainfall.
- Between 1950 and 1990, the region then experienced a strong wet period where above average rainfall fell for 27 out of 40 years.
- Since 1990, a prolonged drying period is being observed. The millennial drought (late 1996 to mid-2010) occurs in this period and more recently the 5-year rainfall totals of 2004 to 2009 and 2014 to 2018 comprise the 2 driest 5-year totals on record for the region. This is an important consideration as recent surface water flows in Salt Creek (at monitoring point SV2) have been significantly lower than those recorded from 1969 to 1982; (refer to **Section 3.8** for more information on surface water flow data).

Seasonally rainfall is variable, with around 60 percent of total annual rainfall falling over the months of May through October. Heavier episodic rainfall (greater than 50 mm/day) generally occurs in Spring and Summer with almost 70 percent of these falls occurring in this period.

[2] http://www.longpaddock.qld.gov.au/silo/

Mean annual potential evaporation (PE) does not vary significantly across the region, with an annual mean of 1,300 mm measured at Anglesea. Further information on evaporation (including lake evaporation) is discussed in **Section 3.2.1**.

3.2.1 Evaporation on Water Bodies

Typically, evaporation from surface water bodies (such as a lake), are calculated using Morton's Lake Co-Efficient or a Synthetic Class A Pan Co-Efficient. However, Morton's Lake Co-Efficient is for a shallow lake, and Synthetic Class A Pan Co-Efficient is for a shallow evaporation-pan. Therefore, to determine evaporation from a deeper lake (i.e., the mine pit void water body), both need to be converted by a co-efficient to relate them to evaporation for a deep lake (greater than 1.0 m depth).

The standard conversion-factor for PAN to lake is generally 0.75 x PE. For the mine pit void, PE was calculated using FAO56[3] and SILO Data Drill system[4] for the site. The results indicated the ratio between the Synthetic Class A Pan Co-Efficient and FAO56 is 0.725; therefore, the unadjusted FAO56 is close to lake evaporation and its direct use without adjustment can therefore be used as the simplest estimate of lake evaporation.

McJannet *et al.,* (2017) undertook a study whereby evaporation from a mine void lake using analytical, actual and modelling approaches were compared. The results found that aerodynamic modelling provided the closest match to actual floating pan evaporation, whilst applying the standard Class A pan measurements sometimes provided poor correlation, especially where shading from steep side walls and high evaporation rates are common (such as in North Western Australia). As the former Anglesea mine, neither has steep sided walls or experiences very large seasonal fluctuations in temperature. As such, using the approach above is considered representative and no direct evaporation measurement is necessary.

Figure 3-3 shows a plot of PE (FAO56) and rainfall from SILO, as well as actual annual rainfall deficit for a site at the mine pit void for a point at the mine pit void (Lat. and Long. of -38.40^{o} 144.15^{o}, decimal degrees). This rainfall deficit was then used across the surface area of a full pit void (approximately 100 Ha at +5.5 m AHD) to determine likely actual evaporative losses as opposed to PE. On average, evaporative losses (rainfall deficit) per year were estimated at 311 mm/year or about 0.31 GL/yr of water at full storage (100 Ha x $1x10^{4}$ x 311mm/year x $1x10^{-9}$).

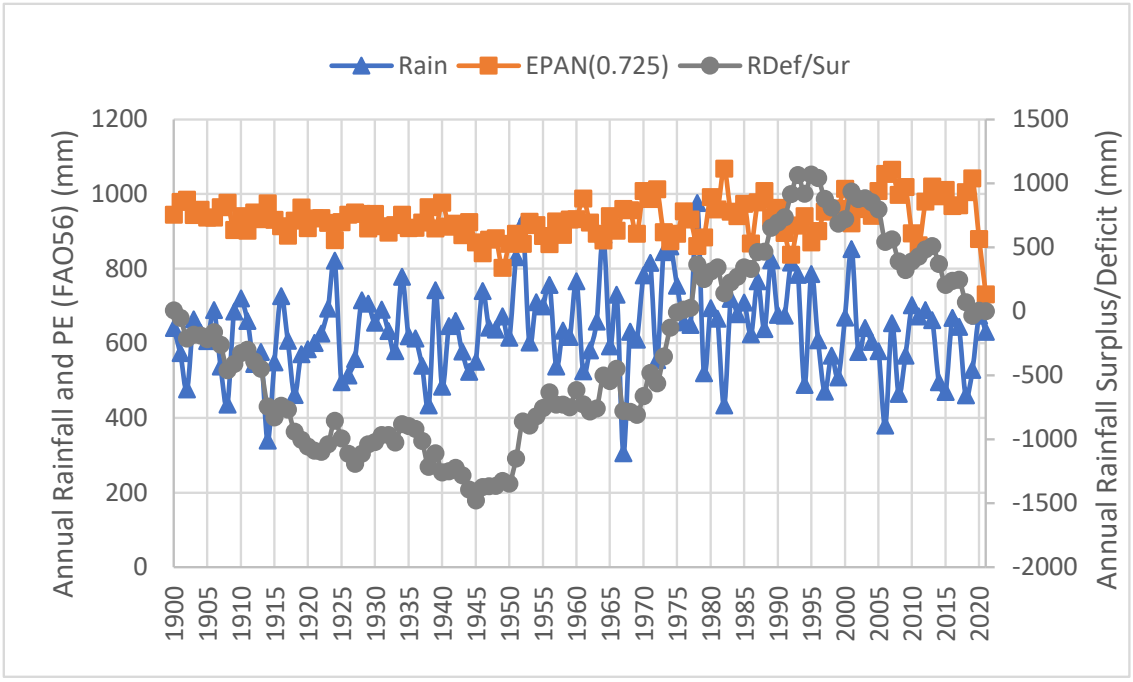

Figure 3-3 Annual Rainfall and PE (FAO56) for a Site at the Mine Pit Void

3.3 Climate Change

As shown in **Figure 3-3** and discussed in **Section 3.2**, there is evidence of three strong climatic cycles over the last 120 years. Between 1900 and 1950, the region exhibited a drying climate, defined by average annual rainfall typically being lower that the LTA rainfall. Between 1950 and 1990, the region then experienced a strong wet period where above average rainfall fell for 27 out of 40 years. Recently, however, the rainfall surplus/deficit has again begun to fall with drier than average conditions dominating over the last 30 years. An important observation from **Figure 3-3** is the rate of decline (slope of the rainfall surplus/deficit) observed over the last 20 years is occurring 1.5 times faster than observed during the drying phase of 1900 to 1950.

As a result of this historical climate variability, the Victorian Government prepared a series of guidelines (Department of Environment, Land, Water and Planning [DELWP], 2016) outlining how the climate change projections can be applied for water resource planning in Victoria. These guidelines are based on 42 global climate models (GCM) and applied to generate climate change projections for Victoria's river basins for the years 2040 and 2065. With respect to this report, the Otway Coast basin is the relevant river basin.

A summary of the climate change projections for the Otway Coast basin are presented below for two projections: low (10^{th} percentile) and high (90^{th} percentile) impact on water availability from climate dependent sources. The results suggest:

- Average daily temperature is projected to increase by 1.0 ^{o}C by 2040 and 1.9 ^{o}C by 2065 relative to the current climate baseline.
- Potential evapotranspiration is projected to increase by 3.7 percent by the Year 2040, and 6.4 percent by 2065 relative to the current climate baseline.
- Average annual rainfall is projected to range from a decrease of 11.7 percent (high scenario) to an increase of 2.1 percent (low scenario) by the Year 2040, with a 3.6 percent decrease in rainfall for the medium climate change scenario. By 2065, rainfall is expected to range from 19 percent reduction (high scenario) to a 0.5 percent increase (low scenario). The median climate change scenario predicts a 5.8 percent relative reduction to the current climate baseline.
- Average annual runoff is projected to range from -25.3% to -6.6 (median = -15.8%) by the Year 2040. By 2065, annual runoff is projected to range from -41.9% to -4.7% (median = - 7.2%) relative to the current climate baseline.

With respect to sea level rise, future rises are projected for key areas in Victoria are based on the 2015 national sea level projections (CSIRO and BoM, 2015). By the 2030s, sea level is projected to rise by around 12 cm (7–18 cm) (relative to 1986–2005) under medium (RCP4.5) and high (RCP8.5) emissions scenarios. By the 2070s, the emissions scenario has greater impact, with increases of around 32 cm (20–46 cm) under RCP 4.5, but up to 42 cm (26–54 cm) under RCP 8.5.

In addition, the Victorian Governments Future Coasts Program[5] is preparing policy of planning for not less than 0.8 m of sea level rise by 2100. Note: if this level of rise did occur it would only impact the estuary. The lowest point of coal mine road which runs between the top of the estuary and the former mixing zone (**Figure 1-1**) has an elevation of 5.0mAHD.

3.4 Soils

Regionally, to the north and west of Anglesea, the soils are dominated by sandy uniform units formed on the Tertiary-aged sediments of the Eastern View Formation (EVF). Further to the east, the dominant soil type changes to the more clay rich soils formed on the more recent Neogene-aged marls and non-calcareous sediments of the Jan Juc Formation and the Demon Bluff Formation (DBF). In the topographically elevated and forested areas in the west, the soils are dominated by texture contrast soils formed on the Lower Cretaceous-aged sedimentary rocks of the Otway Group.

Locally, soils generally exhibit acid duplex profiles from three distinct profile types developed from differing parent materials. The three main characteristics of the vast majority of soils across the site are the distinct texture contrast between the light-textured sandy surface soil and the clay subsoil:

1. Sandy podzols and podsolic soils: These tend to be developed on older Tertiary sediments and therefore tend to be more prevalent on the lower sections of slopes. These highly leached acidic soils are characterised by sandy topsoils and low fertility with deficiencies in phosphorus, potassium, nitrogen, copper, zinc and molybdenum (Pitt, 1977).
2. Lateritic podsolic soils: These are generally developed on the plateau remnants of the Tertiary peneplain. The A horizons of these soils have a loamy texture with an organic aluminium (A1) and bleached A2 horizon, changing sharply to well-structured silty clay at a depth of approximately 40 centimetres (cm). Ironstone blocks and nodules are ubiquitous at around a depth of 1 metre.
3. Acid peaty soils: These are developed in local creek beds and may be up to several metres in depth. Although nutrient levels are high, they are not freely available to plants due to a pH less than 4 (Kentish and Bourne, 1983).

3.5 Catchment Acidity and Acid Sulphate Soils

Acidity in the Anglesea River catchment is a topic that has been researched extensively over the last 20 years and all studies to date acknowledge the catchments naturally high pyrite and sulphur content as the main source of acidity or acid drainage.

In the most recent study, Wong *et al.,* (2020), investigated the distribution and characterisation of acid sulfate soils in the Salt Creek and Marshy Creek Swamplands. The study involved field sampling of 28 sites within the course of the Anglesea Swamplands and a further 25 sites along the marshlands associated with Salt Creek.

The study identified three modes of acidity at each site:

i) potential sulfidic acidity, sourced from sulfidic sediments containing pyrite and monosulfides;
ii) labile acidity, which is existing acidity and can be rapidly mobilised; and
iii) retained acidity, which is existing latent acidity usually stored in minerals such as jarosite. In addition, acid neutralising capacity was also analysed and net acidity determined.

The report found that both Salt Creek and Marshy Creek contain substantial volumes of acidity in a form that can be mobilised rapidly. Marshy Creek contains higher concentrations of labile acidity which can be transported readily in surface water and groundwater, whereas Salt Creek contains higher concentrations of retained acidity which can be slowly released over time.

Given it is known that the catchment is naturally acidic, the hydrogeological system contributes to acid generation and transport in 3 ways:

- fluctuating water tables - dropping water tables introduce air into moist pore spaces of the unsaturated zone.
- dissolved oxygen can be transported to pyrite by groundwater recharge.
- groundwater flow, specifically in the vadose zone, transports any acid generated.

These factors are schematically shown in **Figure 3-4**.

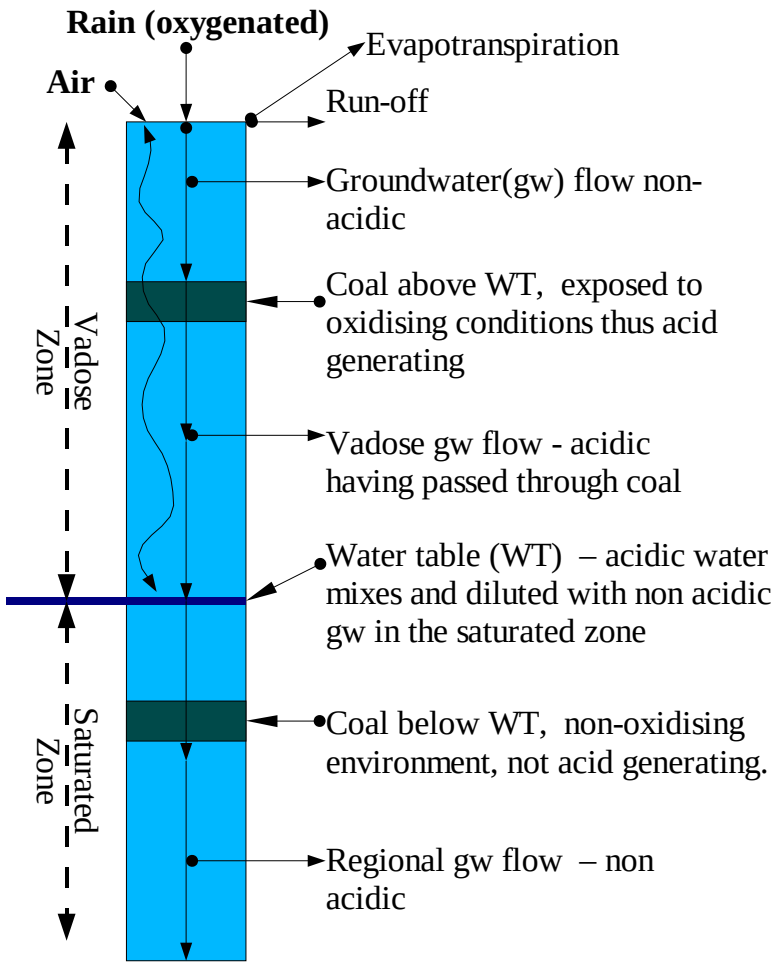

Figure 3-4 Model of Acid Generation and Transportation from Sulphide Containing Units of the Anglesea Geological Sequence (after Tutt 2008)

The key processes of the cycle which directly influence acid generation and transport in the Anglesea catchment are precipitation, infiltration, percolation and groundwater to lakes and streams, refer **Figure 3-5**.

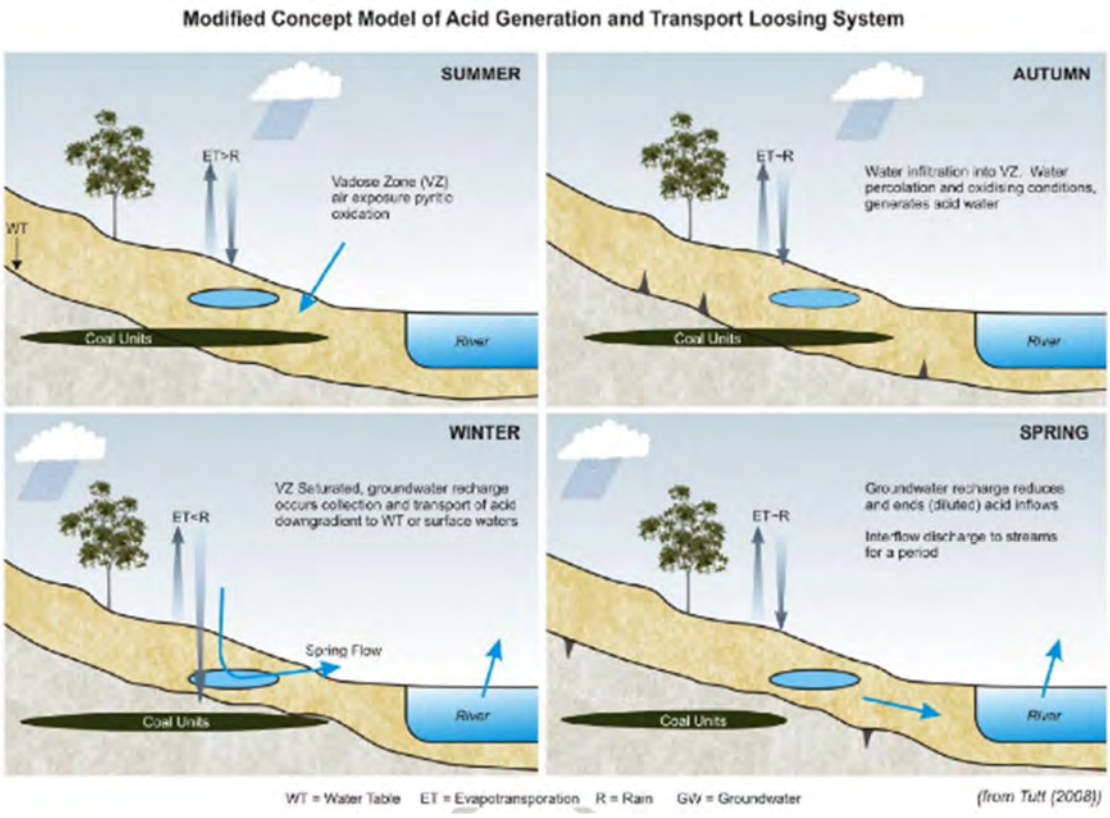

Figure 3-5 Modified Conceptual Model of Seasonal Acid Generation and Transportation Mechanisms (after Tutt 2008, reference GHD 2013)

As depicted in **Figure 3-5**, some acid generation and transportation should theoretically occur every year. Over winter and spring, water infiltrates and percolates into the vadose zone oxidising pyrite and transporting acidic water down gradient. This water can either discharge as a spring flow to the surface or mix with the existing groundwater within the shallow alluvial aquifer.

Seasonal rainfall therefore directly influences the rate of acid generation and transportation. Variation to normal weather patterns, including extended dry periods, which may drop the water table and affect acid generation and transportation, potentially creating scenarios such as:

- low groundwater recharge causing reduced generation and transportation of acid in the systems and a potential build-up of acid in pore spaces.
- high groundwater recharge causing greater oxidation of pyrite plus increased transportation as percolating groundwater flushes pore water from the vadose zone.

In addition to Wong *et al.,* (2020), other detailed studies that summarise the sources of acidity in the catchment are summarised in **Table 2-4.**

Section 5.6 presents a more detailed conceptualisation of the acid generation and transportation processes. This section along with the hydrogeological conceptualisation (including aquifer interconnectivity and an analysis of groundwater and surface water data over a logger dataset), presented within this report addresses many of the recommendations in Wong *et al.,* (2020).

3.6 Groundwater Users

The location of the groundwater users (such as private and commercial water bores) are shown on **Figure 3-6**. Groundwater bores within the local area have been determined through a search of the Victorian Water Measurement Information System (WMIS), refer **Figure 3-6**. The WMIS database was undertaken in October 2021 to identify registered bores within a 10 km buffer of the mine pit void and within the Jan Juc GMA.

Figure 3-6 shows a high density of stock, domestic and irrigation bores are located to the northeast of the Jan Juc GMA (north of Torquay); however, these bores are generally shallow and intersect the groundwater resources of the Beaumaris Sandstone (formerly known as the Moorabool Viaduct Sands) or the shallow sediments of the Demon Bluff Formation (DBF). Of these bores, only two appear to be completed in the UEVF. Bore ID 68160 is completed to a depth of 278.9 m and located ~3 km southeast of the mine near the coast. Bore ID 68179 is completed to a depth of 28 m in coal and is approximately 8.5 km northeast of the mine. This bore sits within the Jan Juc syncline and due to the Bells Beach Anticline separating the UEVF at the mine and this bore, they are not connected.

Beginning 2007, Barwon Water installed seven production bores (GW1 to GW7) in the LEVF, refer **Section 2.2.2**.

Lastly, the Moriac Quarry has a licence to extract 250 ML/year. The quarry is located approximately 13 km north of the mine pit void with groundwater extracted from the LEVF (up-gradient of the site) and used for industrial sand washing purposes.

3.7 Potential Environmental Sensitive Receptors and Groundwater Dependant Ecosystems

Across the catchment there have been many studies that have assessed the nature and extent of GDEs that may occur within the catchment along with the aquatic ecology of the surface water systems. Many of these are summarised in **Table 2-3** with the section below providing the most current understanding. Specifically, the following Environmental Sensitive Receptors (ESRs) and potential GDEs are discussed:

- Anglesea River and Salt Creek Permanent Pools.
- Anglesea River and Salt Creek Vegetated Marshlands.
- Anglesea River Estuary.

Additional information on the terrestrial and aquatic ecology of the catchment can be found by Ecology Australia (2007–2013) and GHD (2012–2016).

3.7.1 Anglesea River and Salt Creek Permanent Pools

As part of Barwon Waters Anglesea Borefield Project (ABP), a number of persistent pools in upper catchments of both water courses (**Figure 3-6**):

- Upper Anglesea Persistent pools (named AGP1-B, AGP2 and ASP7); and,
- Salt Creek Persistent pool (SGP1-a and SGP2-B).

These pools (or potential GDEs) were identified as key asset points in the outcrop area associated with the LEVF, which had the potential to be significantly impacted by dewatering activities, as:

- They appeared to be permanent pools and therefore considered baseflow dependent.

- They are located in the interpreted LEVF outcrop area and hence likely to be in direct connection with the aquifer being pumped, also situated at the LEVF outcrop area closest to the Barwon Water borefield, and therefore impacts were possible in the short term.
- Southern Pygmy Perch was identified in the Salt Creek pools suggesting the pools may have a relatively high ecological value as habitats for these fish.

However, GHD 2011, undertook a detailed investigation on these pools. These studies used stable oxygen isotopes, chlorofluorocarbons and radiocarbon for better understand surface water and groundwater interactions. The results, as well as yearly surface water quality monitoring from 2012 to 2019 confirmed that these pools, with the exception of SGP1-A, are not in direct connection with the underlying aquifer and not baseflow dependant, rather they are perched systems recharged by surface water flows.

3.7.2 Anglesea River and Salt Creek Vegetated Marshlands

Groundwater dependent ecosystems as defined by the Ministerial guidelines for groundwater licensing and the protection of high value groundwater dependent ecosystems (DELWP, 2015) means those ecosystems that require access to groundwater to meet all or some of their water requirements so as to maintain the communities of plants and animals and ecological processes they support and the ecosystem services they provide. This definition has also been used in the recent Anglesea River and Estuary Environmental Flow Study (GHD, 2021).

Whilst there is always conjecture in determining the degree of groundwater reliance of certain GDEs (a process that often takes years and a high level of detailed studies to define), GHD (2021) presents that there are some vegetated communities in the swamplands within the Anglesea River and Salt Creek Catchment (defined in this report as the vegetation on top of the Alluvial Swamp Aquifer (ASA)) that rely on less than 10 percent groundwater contribution and therefore meet the definition of a GDE. These swamplands are typically found in the mid and upper reaches of Salt Creek and Marshy Creek and are shown on **Figure 3-6**.

Importantly, no other GDEs or areas where they could exist were identified, and to date no other GDEs have been identified where they are in direct connection to the UEVF.

3.7.3 Anglesea River Estuary

The Anglesea River Estuary is an important environmental and community asset in the region. Multiple lines of evidence suggest that the estuary is hydraulically disconnected from the main aquifers within the UEVF and LEVF:

- Monitoring of shallow aquifers (DBG/ASA) in the vicinity of the former power station show no changes in water level despite climatic events and aquifer stresses.
- The top of the UEVF under the estuary occurs at a depth of 115 metres below ground level (mbgl) (refer bore log for P14, GHD, 2010).
- Underneath Marshy Creek adjacent to the former power station, ~30 m of coal, clay and silty clays separate the base of the Creek to the top the UEVF.
- Pre-development (Hancock, 1967) noted small artesian conditions near the former power station site from a bore screened 138 mbgl. This indicates that the presence of clay layers between the surface and the water bearing zones are strongly confining.

Refer **Section 5.5** for further information on potential surface water and groundwater interactions and **Section 3.7** for a discussion of groundwater dependant ecosystems.

3.8 Catchment Hydrology

The main surface drainage features in the Anglesea area are:

- Salt Creek and its associated swamps and tributaries (e.g., Breakfast Creek).
- Upper Anglesea River/Marshy Creek and associated swamps and tributaries.
- Lower Anglesea River (Estuary).

Surface water features including monitoring points (i.e., gauging stations) are show on **Figure 3-6**. Surface water segments are shown in **Figure 3-7**.

3.8.1 Anglesea River

The Anglesea River is described in three segments (**Figure 3-7**):

- Upper reaches of the Anglesea River (i.e., Marshy Creek).
- Swamps associated with the mid-reaches of Anglesea River/Marshy Creek.
- Lower Anglesea River.

Geographically, the Lower Anglesea River is defined to begin downstream of monitoring point SP6 at Coal Mine Road. The swamps are located between monitoring point SP6 and 1 km upstream of monitoring point AV3. The upper reaches are located above this point. **Figure 3-6** shows the location of surface water features and monitoring points. The total catchment extent is approximately 65 km^2. Swampy heath and heathy woodlands predominate in the catchment. **Table 3-1** discusses the Anglesea River inter-gauge flow differences. Flow statistics described in **Section 3.8.1.1** to **Section 3.8.1.3**.

3.8.1.1 Upper Anglesea River/Marshy Creek

The upper reaches of the Anglesea River/Marshy Creek are ephemeral; however, GHD (2013) reports that several non-groundwater fed, permanent pools exist across its reach (monitoring points AGP1- A, AGP1-B and AV1, **Figure 3-6**). These reaches drain the eastern flanks of the Otway Range, and much of the outcropping LEVF and MEVF from the west to the east near Gum Flats Road.

The ephemeral nature of flow within the Anglesea River catchment is evident in stream gauging data. Upstream monitoring point AV1 shows around 250 days per year (nearly 70 percent of the year) with no recordable flow. **Figure 3-8** shows flows since 2009 and **Figure 3-9** for historical flow during 2010.

3.8.1.2 Swamps

The swamp associated with Anglesea River/Marshy Creek is primarily located between AV3 and SP6 near the former power station. Within this stretch, surface water flow is ephemeral and usually dry during the summer; however, it has a number of wetlands that may be present year-round (GHD, 2013). During large first flush events of these swamps (i.e., first flows after a prolonged period of no flow), significant volumes of low pH water can be flushed into the estuary (Lower Anglesea River), which cause low pH, metals precipitation and, in some cases, fish kills. Historical data shows that the estuary exhibits low pH (<5) in two out of every three years.

At monitoring point AV2, which is located just upstream of the former power station (**Figure 3-6**), data indicates that there are on average 134 days per year (37 percent of the year) that show no recordable flow for the period 2009 to 2021.

For periods where baseflow is sustained for longer periods than average, **Figure 3-9** presents typical flow duration curves using a runoff event in 2010 from AV2 (lower catchment) and AV1 (upper catchment). This shows discharge in AV2 runs for a longer period of time than in the upper catchment (**Table 3-1**).

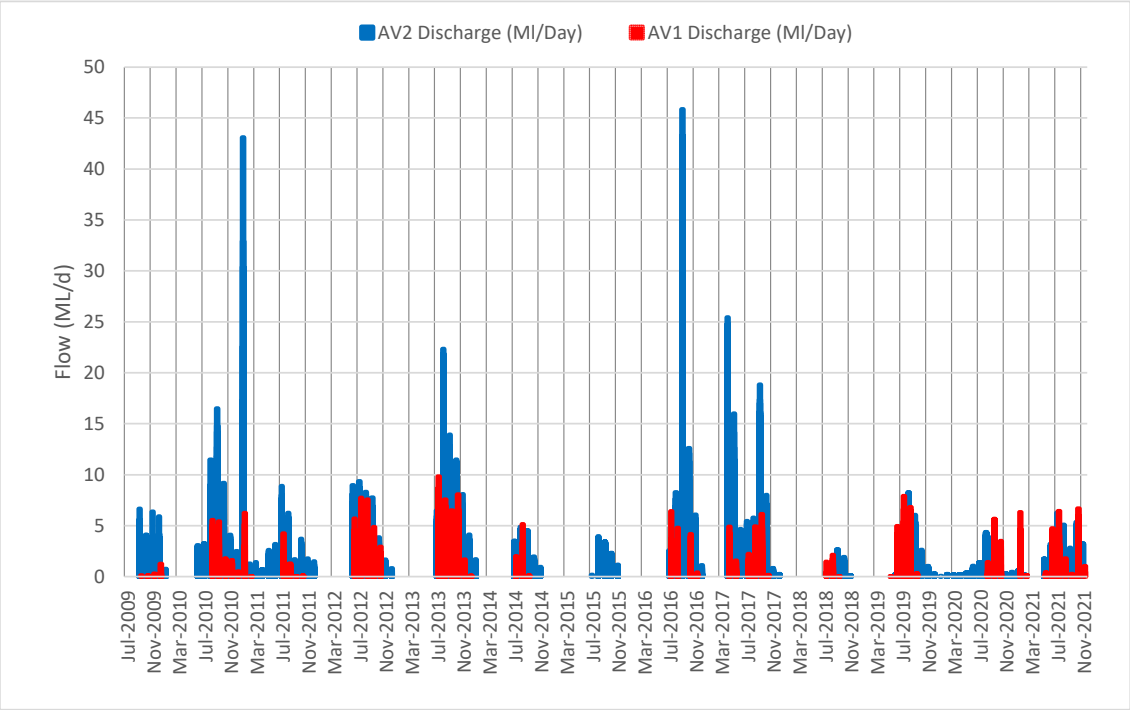

Figure 3-8 Total flow (by month) for the Anglesea River (AV1 & AV2) from 2009 to 2021

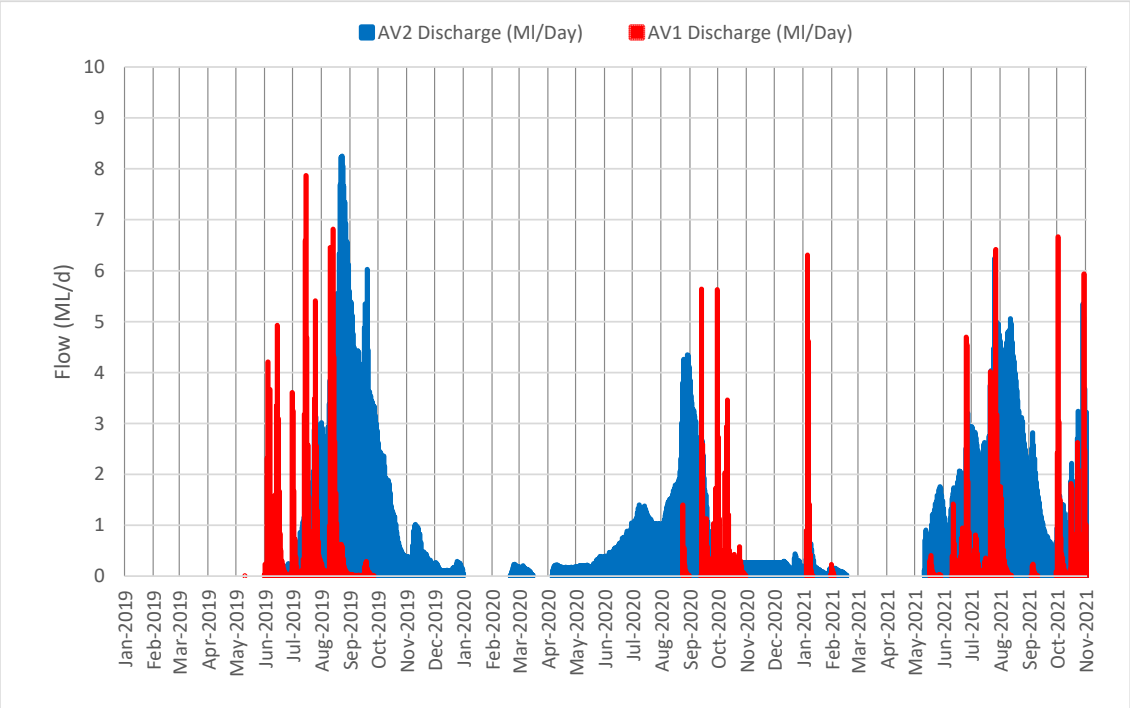

Figure 3-9 AV1 vs AV2 Baseflow Comparison 2019 to 2021

Table 3-1 Anglesea River Inter-Gauge Flow Differences

Monitoring Point	Comparison
Between monitoring points AV1 and AV2	Gaining conditions (i.e., where surface water flow gains occur as water travels downstream) are identified throughout the data record for these monitoring points. These stream gains are due to continued runoff and drainage of the catchment downstream of the upstream monitoring point. Again, this is as expected due to the increasing catchment size and runoff potential moving downstream. Short-term losing stream conditions were identified following prolonged dry periods. In these cases, rainfall recorded in the upstream monitoring point (AV1) probably infiltrated relatively dry ground and was subsequently attenuated in the swamp prior to reaching AV2.

3.8.1.3 Lower Anglesea River

At the lower reaches of the Anglesea River catchment in the region of the site and downstream, flows had previously been artificially supported by a 3-5 ML/day of approximately pH 7-8 water discharges from Alcoa's power station (EPA License EM32162), refer **Figure 2-1**. In addition to this discharge, the lower reaches of the Anglesea River received periodic baseflow (as throughflow) from the ASA formed in the permeable alluvial sediments deposited along the creek valley. The effect of Alcoa's alkaline buffering capacity along with peak flows from Salt creek and Upper Anglesea River on the pH of the Estuary is clear on **Figure 2-1**.

3.8.2 Salt Creek

The total catchment area of Salt Creek is approximately 48.7 km^2 and primarily resides within Anglesea Heath, containing significant quantities of heathy woodland and swampy heath with peaty soils. For the purposes of this report, Salt Creek is described in two segments: Upper Salt Creek and Lower Salt Creek, **Figure 3-7**.

Geographically, Upper Salt Creek is defined as the reach above the marshland (near monitoring point SV4) with the lower reaches being defined from this point to monitoring point SV2 along the diversion channel. Flows occurring in the lower reaches have been modified over time as the mine footprint developed. A portion of the Salt Creek catchment has been modified whereby surface water in this location now runs into the pit void as opposed to Salt Creek or the diversion channel. The physical size of the mine void today, plus its local drainage area represents approximately 8% of the salt creek catchment, however the actual impact on the historical flows to Salt Creek would be dependent on the original topography and any additional catchment introduced by the diversion channel.

Monitoring point locations are shown in **Figure 3-6**. **Table 3-2** discusses inter-gauge flow differences across Salt Creek and flow history is shown in **Figure 3-10** (since 2009) and **Figure 3-12** (total period).

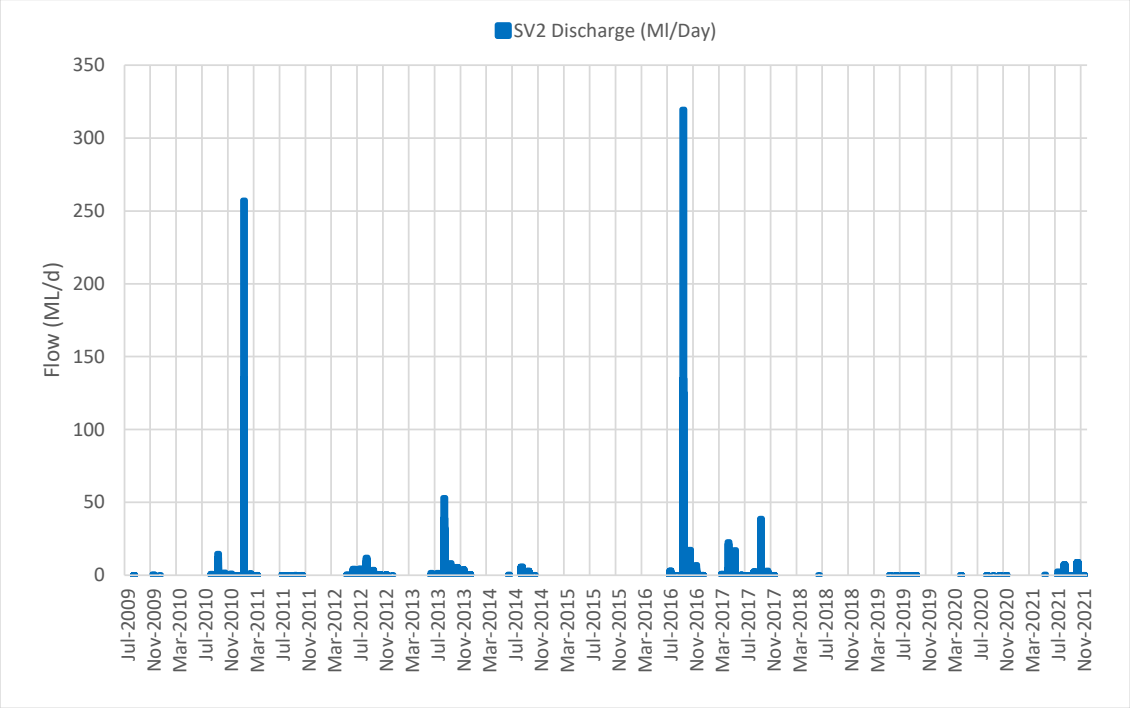

Figure 3-10 Total Flow (by month) for Salt Creek from 2009 to 2021

Table 3-2 Salt Creek Inter-Gauge Flow Differences

Monitoring Point	Flow Description
Between monitoring points SV3 and SV1	• These monitoring points show primarily gaining stream conditions, often following large rainfall events. This is where surface water gains occur as water travels downstream, due to continued runoff and drainage of the catchment downstream of the upstream monitoring point (SV3). This is as expected given that catchment size increases in the downstream direction. Also, the likely addition of groundwater from perched water tables would contribute to gaining stream conditions. • Losing stream conditions occur temporarily, often at the commencement of the wetter winter period. This is possibly due to increased infiltration rates to relatively dry and unsaturated sub-surface soils.
Between monitoring points SV1 and SV4	• Short-term surface water flow losses were identified at downstream monitoring points, primarily due to rainfall runoff and infiltration subsequent to significant rainfall events. • Longer term surface water flow gains occur at SV4 (upstream of the swamp). Flow at this monitoring point continues subsequent to rain events and subsequent to flow upstream. This shows the increase in catchment size and as such, runoff potential, available to the downstream monitoring point (SV4). • A period of no flow was identified between January and April 2012.

Monitoring Point	Flow Description
Between monitoring points SV4 and SV2	• These monitoring points, situated upstream and downstream of the main swamp, predominantly show minor flow differences. They frequently show losing stream conditions, whereby surface water is attenuated by the swamp, either through evapotranspiration or infiltration. This results in less net flow passing through the down-swamp monitoring point (SV2). • Gaining stream conditions occur periodically during significant rain events, whereby there is more surface water flow at the down-swamp monitoring point compared with the up-swamp monitoring point. This results in cyclical flushing of the swamp and prolonged flow to the downstream monitoring point (SV2) compared with the up-swamp Anglesea River Catchment.

3.8.2.1 Upper Salt Creek

Upper Salt Creek, above the Breakfast Creek confluence (near SV1), is ephemeral; however, Breakfast Creek itself (a tributary to Salt Creek) appears to be the only section within the Anglesea River/Salt Creek catchment that appears to be perennial (GHD, 2013). This is supported by subsequent surface water monitoring reported by GHD (2016b).

Between SV1 and SV4, where the LEVF outcrops, baseflow is ephemeral with permanent pools of water (monitoring points SGP2-B and SV4). Mostly year around, these upper reaches appear to be mainly losing surface water reaches. **Figure 3-11** shows the flow differences in 2013 from upper catchment monitoring points (SV1 to SV3) to the lower reach (SV2).

3.8.2.2 Lower Salt Creek

Lower Salt Creek and its associated swamp (between SV4 and SV2) reports historical spring surface water flows with dry periods occurring at most other times of each summer (**Figure 3-11** and **Figure 3-12**). In this location, the Creek is confined to a more incised channel and is also inferred to be a potential losing stretch of surface water (GHD, 2013).

The lowest monitoring location in Salt Creek is along the diversion channel (monitoring point SV2), which generally only records flows during the winter months when high intensity and large duration rainfall events occur.

Total stream flow data at SV2 (Lower Salt Creek) ranges from 1967 to 1982 and 2009 to 2021 and is presented in **Figure 3-12**. This shows an average stream flow of 2,300 ML/year, ranging from years of no flow (2015) to 9,000 ML/year (1978). In the latter period, flows are significantly lower than those observed in 1967 to 1982. **Section 3.8.3** explores the observed flow reduction further.

At SV2, daily flow exceeding 1 ML/day occurs approximately 35 percent of the time and completely dry conditions occur for approximately 50 percent of the time based on existing gauge records.

Lastly, it should be noted that only anectodical data for flow exists between the period of 1983 and 2009. Whilst no measured flow data exists between this period, a significant rainfall event (approximately 200 mm over 2 days), led to the overtopping of the Salt Creek diversion channel embankment and a volume of water estimated between approximately 3 and 4 GL entering the mine void (pers. com C. Rolland, 2016, former Alcoa Mine Manager).

3.8.3 Reduction in Surface Water Flows

Stream flows within the catchment have significantly declined since monitoring began in 1967. Numerous theories have postulated causes for this from the impact of climate change (such as decreased rainfall and increase in evapotranspiration) to an increase in water loss to underlying aquifers. This section explores these questions and outlines the most probably cause.

Firstly, the relationship between rainfall and runoff is not linear. (CSIRO, 2011) suggest annual variations in rainfall are typically amplified as two- to three-times larger variations to annual runoff. So a 10% reduction in rainfall typically leads to a 20 to 30% reduction in runoff. However, this rule of thumb does not always hold true especially in catchments dominated by large elevation differences and steel slopes (such as the Otway's). In fact, a study undertaken by (Pott and Chew, 2011) in the Campaspe region of Victoria found that observed reduction in annual runoff during 1997–2008 was 59% lower compared to its long-term average despite rainfall only falling by 15% during this period.

For Salt Creek, this reduction is even higher with a 16% reduction of rainfall (2010 to current c.f 1968 to 1981) leading to a 89% reduction in flow. Whilst this does seem severe and fingers point to additional water must also be losing from the catchment, its not that unexpected considering the results from the Campaspe trial (Pott and Chew, 2011) and the fact that the majority of Salt Creek is located within a high relief catchment and the last stretch of the catchment has been modified by mining with surface water runoff being diverted into the mine void (approx 8%).

Furthermore, an additional study undertaken by (Saft *et al.,* 2015) looked at data from 228 catchments from south-eastern Australia (East Coast and Murray-Darling Basin water divisions) that are unregulated, relatively unimpaired, not nested, and with catchment areas between 50 and 2000 km^2. The study aimed to address whether annual rainfall-runoff relationships are significantly different during extended dry periods, compared with the historical norm and if so what catchment and climate characteristics cause these changes.

The results found 79% of all catchments experienced a downward shift in the best-fit rainfall-runoff relationship during extended dry periods. This means that a persistent drought results in lowered runoff generation rates for similar rainfall amounts. Thus, in a sequence of years with reduced rainfall we would expect not only lower runoff due to the lower rainfall, but also less runoff than would be expected from the historical functional dependency of runoff on rainfall.

To relate the above with Salt Creek, and in recognition that following the millennial drought multiyear rainfall from Wensleydale in 2005/06 was the 4th driest 2-year cumulative period on record (from 122 years); 2015/2016 was the 5th driest and 2018/19 was the 8th driest on record. In addition, the cumulative 5-year period 2005 to 2009 and 2014 to 2018 represent to 2 driest 5-year cumulative rainfall totals on record being 24% and 21% drier than each cumulative 5-year average between 1968 to 1981.

Therefore, if a 15% reduction in annual rainfall causes a 59% reduction in surface water flow in the Campaspe region of Victoria, it is entirely possible that >20% reduction in rainfall can lead to almost a 90% reduction in flow for a catchment with the relief characteristic of Salt Creek.

4 Protected Environmental Values and Water Quality Summary

4.1 Environment Protection Act 2017

The *Environment Protection Act 1970* was superseded by the *Environment Protection Act 2017* ("new Act"), which came into force on 1 July 2021. The general environmental duty (GED) is at the centre of the new Act and it applies to all Victorians. The GED requires that the entity engaging in an activity must reduce the risk of harm:

- To human health and the environment.
- From pollution or waste.

Subordinate legislation is the group of tools that support the new Act, which include Regulations and the Environment Reference Standard (ERS). Under the new Act, State Environment Protection Policies (SEPPs) are replaced by ERS. The ERS includes the SEPP (Waters), which presented the framework for the protection and management of water quality in Victoria, covering surface waters, estuarine and marine water and groundwater. The purpose of the ERS is to support the protection of human health and the environment from pollution and waste by providing benchmarks to be used to assess and report on environmental conditions in the whole or any part of Victoria.

4.1.1 Environmental Values and Adopted Assessment Criteria

The environmental values of waters (both surface water and groundwater) are defined in Table 5.1 of Part 5, Division 1 of the ERS, with the first column listing the environmental value and the second column describing what the purpose or intent of that use is. These are summarised in **Table 4-1**.

Table 4-1 Environmental Values of Waters

Environmental value	Description of Environmental Value
Water dependent ecosystems and species	Water quality that is suitable to protect the integrity and biodiversity of water dependent ecosystems. This integrity and biodiversity includes – • the integrity of riparian vegetation as it contributes to the health of water dependent ecosystems and bank stability. • groundwater quality that does not adversely affect surface water ecosystems. • groundwater quality that does not adversely affect natural ecosystems that require access to groundwater to meet all or some of their water requirements on a permanent or intermittent basis to maintain their communities of organisms, ecological processes and ecosystem services. This includes wetlands, rivers and streams reliant on groundwater baseflow, some terrestrial vegetation and some estuarine and near-shore marine systems, stygofauna and troglofaunal. • maintenance of fish passage.
Human consumption after appropriate treatment	Surface water quality that is suitable for use by drinking water suppliers for delivery, after appropriate treatment, to consumers of drinking water. Surface water quality that is suitable for use by the Wonthaggi desalinisation plant.
Potable water supply	Groundwater quality that is suitable for raw or potable water supply
Potable mineral water supply	Groundwater quality that is suitable for drinking and, in its natural state, contains soluble minerals and natural gases causing effervescence

Environmental value	Description of Environmental Value
Agriculture and irrigation	Water quality that is suitable for agricultural activities such as stock watering and irrigation, as well as a range of other uses such as the irrigation of domestic gardens, commercial agriculture, parks and golf courses
Human consumption of aquatic foods	Surface water quality that is suitable to support the availability and safe human consumption of fish and any other aquatic plant, algae or invertebrate from natural populations, commercial and recreational catch
Aquaculture	Surface water quality that is suitable for the production of fish and any other aquatic plant, algae or invertebrate for human consumption via aquaculture
Industrial and commercial use	Water quality that is suitable for industrial and commercial use
Water-based recreation	Water quality that is suitable for primary contact recreation (for example swimming, diving, water skiing, caving and spas), secondary contact recreation (for example boating and fishing) and for aesthetic enjoyment
Traditional Owner cultural values	Water quality that protects the cultural values of Traditional Owners, having recognised primary responsibility for protecting the values of water for cultural needs, to ensure that Traditional Owner cultural practices can continue. Values may include traditional aquaculture, fishing, harvesting, cultivation of freshwater and marine foods, fish, grasses, medicines and filtration of water holes.
Navigation and shipping	Surface water quality that is suitable for the transportation of passengers and cargo by ship and for harbour facilities
Buildings and structures	Groundwater quality that is not corrosive to buildings, structures, property and materials
Geothermal properties	Groundwater quality that will not affect the natural thermal capacity (including temperature) of the groundwater

Applicable protected environmental values for surface water and each groundwater segment (**Section 4.1.2**) were selected based on the protected environmental values specified in the ERS for the Inland segment Central Foothills and Coastal Plains and the Marine segment of Central Bass.

The National Environment Protection (Assessment of Site Contamination) Measure 1999 (ASC NEPM) (NEPC, 2013) and ERS references those guidelines for the risk-based assessment of water quality depending on the different environmental values to be protected:

- National Health and Medical Research Council (NHMRC)/National Resource Management Ministerial Council (NRMMC) (2011) Australian Drinking Water Guidelines 6 Version 3.4 Updated October 2017.
- Australian and New Zealand Environment and Conservation Council (ANZECC)/ Agriculture and Resource Management Council of Australia and New Zealand (ARMCANZ) (2000) Australian and New Zealand Guidelines for Fresh and Marine Water Quality:
  - Aquatic ecosystems
- ANZECC/ARMCANZ (2000) Australian and New Zealand Guidelines for Fresh and Marine Water Quality:
  - Agriculture and Irrigation.
    - Stock watering.
    - Irrigation.
- Primary Contact Recreation[1]

- ANZECC/ARMCANZ (1992) Australian and New Zealand Guidelines for Fresh and Marine Water Quality:
  - Industrial Water use.
- NHMRC (2008) Guidelines for Managing Risks in Recreational Water for primary contact for bathing and swimming.

The naturally occurring acidity of surface water within the catchment and elevated concentrations of metals (aluminium, iron, manganese, nickel and zinc) exceeds applicable criteria and naturally precludes these environmental values. The naturally poor water quality has caused periodic significant fish kills documented in 2000, 2007 and in spring 2010 to early 2011 (Maher, 2011) and more recently. Furthermore, Maher (2011) noted that the water in the Anglesea River, its tributaries and its estuary, frequently becomes acidic (i.e., pH less than 2.5), for short periods following extended dry periods. Normally, background pH in both systems is between 3.0 and 4.5.

Therefore, and as discussed in the ERS[6], an environmental value may not apply to groundwater or surface water if the background water quality exceeds the relevant objective, and as a result, the environmental value cannot be achieved or maintained.

4.1.2 Relevant Groundwater Segment and Environmental Values

The ERS sets out the environmental values of groundwater to be protected. The ERS classifies groundwater into seven segments on the basis of background TDS levels. Each segment has defined environmental values for protection, and the ERS specifies that all of these environmental values must be protected. Environmental values of groundwater are considered to be precluded when relevant groundwater quality objectives for those environmental values have been exceeded.

The ERS outlines the applicable and protected environmental values of groundwater as detailed in **Table 4-2**. The adopted segment classification for the UEVF based on the ERS is highlighted.

Table 4-2 Protected Environmental Values for Groundwater

Environmental Value	Segment (TDS mg/L)						
	A1 0-600	A2 601-1,200	B 1,201-3,100	C 3,101-5,400	D 5,401-7,100	E 7,101-10,000	F >10,001

4.2 Water Quality Summary

4.2.1 Mine Pit Water Quality

Surface water has collected within the low point of the mine pit and consists of rainwater runoff and groundwater recharge from the UEVF and the overlying DBF sediments. **Table 4-3** presents a summary of analytical water quality data from annual sampling conducted from 1999 to 2020, and monthly sampling from May 2021 to July 2022 during the groundwater pumping test and recovery period.

Between July 1999 and July 2022, analysis of the mine pit water has reported limited variability of the majority of analytes measured above the limit of reporting (LOR). As shown on a piper diagram, (**Figure 4-1**), the majority of the water samples plot as a sodium chloride (NaCl) water type. The dominance of this water type is most likely related to the depositional environment of the Eastern View Formation (sub-littoral) and the geochemical influence on the younger aquifer sediments of the Demons Bluff and Boonah Formations. The mine water body is also characterised by a sulfate signature which is likely influenced through run-off from the overburden material (reworked Demons Bluff and Boonah Formations) which is present surrounding the mine void.

TDS are observed to vary between 1,200 and 2,200 mg/L and this appears to be influenced by increases in major ions particularly sulfate. These variations may be related to the differing chemistry of groundwater and mine pit void runoff that contribute to the pit water body. Although runoff is considered to comprise a small component of the water body volume, the sample location could be locally influenced by runoff to a greater extent than groundwater discharging to the water body. The magnitude and trend for sulfate and calcium appear to be similar, suggesting they are derived from similar sources. Historically, the water body has reported a sodium chloride water type; however, the sample events in 2017 and 2020 recorded higher concentrations of sulfate and calcium and a water type, sodium sulfate. The same observation is made for minor metal ions such as aluminium and boron. Concentrations of total iron appear to correlate with pH. Total iron concentrations increase when pH decreases, which is likely to be attributed to increased concentrations of soluble ferrous iron as pH drops.

The natural background surface water quality in the area is characteristic of the low pH, elevated aluminium, boron and other trace metals as reported within the mine pit void. This is further discussed in **Section 4.2.2**.

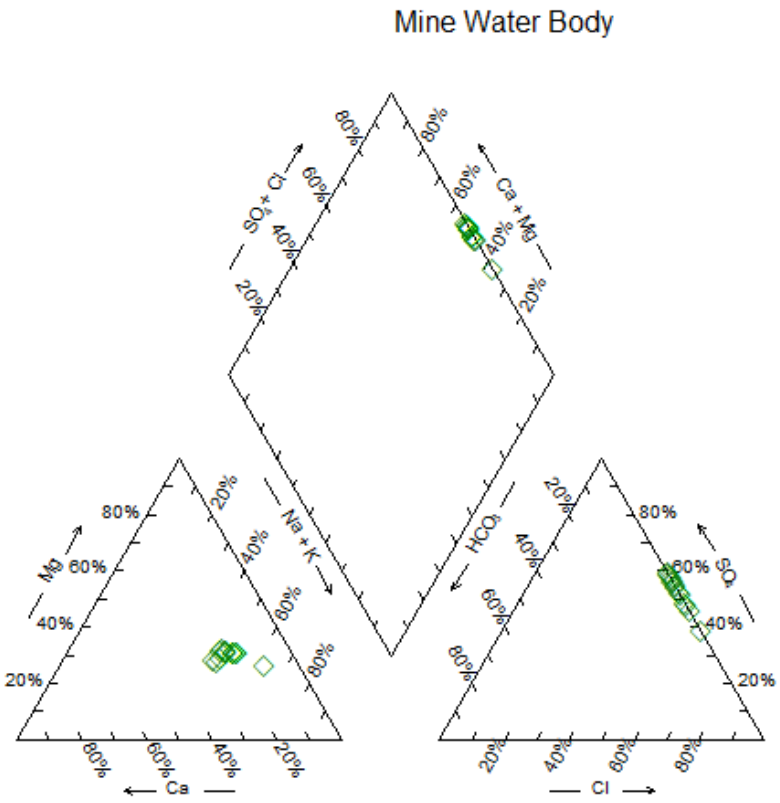

Figure 4-1 Mine Water Piper Diagram

Table 4-3 Mine Pit Water Quality Summary

Analyte	Units	Pre-Pumping Test (1999 – 2020)					During Pumping Test (May 2021 – July 2022)				
		Mean	Median	Low	High	90th percentile	Mean	Median	Low	High	90th percentile
pH		3.35	3.35	2.8	4.28	3.55	3.55	3.53	3.36	3.72	3.64
TDS	mg/L	1562	1510	1200	2200	2052	1732	1715	1520	2020	1992

4.2.2 Catchment Surface Water Quality

This section provides a discussion on historical onsite surface water quality and surface water quality from upstream areas across the catchment. Surface water monitoring locations are shown on **Figure 4-2**.

4.2.2.1 Onsite (Former Power Station) Surface Water Quality Summary

The surface water interaction between natural, but highly modified, and managed surface water flows generated on-site was investigated in detail for the *2012 53V Audit Report* (GHD, 2012). It should be noted that the surface water quality data collected and reviewed as part of the audit was during operations of the power station. To provide context to the historical sampling, the components of flow at each sampling point are consolidated into a flow diagram (**Figure 4-3**), refer to Figure 4-3 GHD (2012) for an understanding of coal mine to power station water budgets. This is important to understand as the majority of data points used to undertake the technical assessments (i.e., groundwater and surface water modelling), only incorporated data points upstream of the mixing zone (SV1-4) and (AV1-3).

A limited dataset for Salt Creek (2010 and 2011) and Marshy Creek (2008 to 2011) was reviewed as part of the audit. The analytical schedule included field parameters (temperature), inorganics (colour, turbidity, total solids, total suspended solids, pH and electrical conductivity [EC]), iron and trace metals (aluminium, boron, nickel and zinc). Detailed flow data was also available for these two surface water systems at three locations upstream of the former power station (2009 to 2012).

Based on the assessment presented in the following sections, natural (geo-genic) sources of low pH and aluminium, boron and zinc constituents have been identified in surface water flowing onto the site. **Table 4-4** presents a summary of analytical water quality data from upstream monitoring points AV2 (Upper Anglesea River) and SV2 (Salt Creek). This up-catchment surface water then mixed (historically) with the treated wastewater discharges from the power station (Ash Pond 2), providing a subsequent ameliorating effect on pH (discharges were more alkaline in nature).

The characteristics of each of the identified surface water areas are described in **Section 4.2.2.2** onwards.

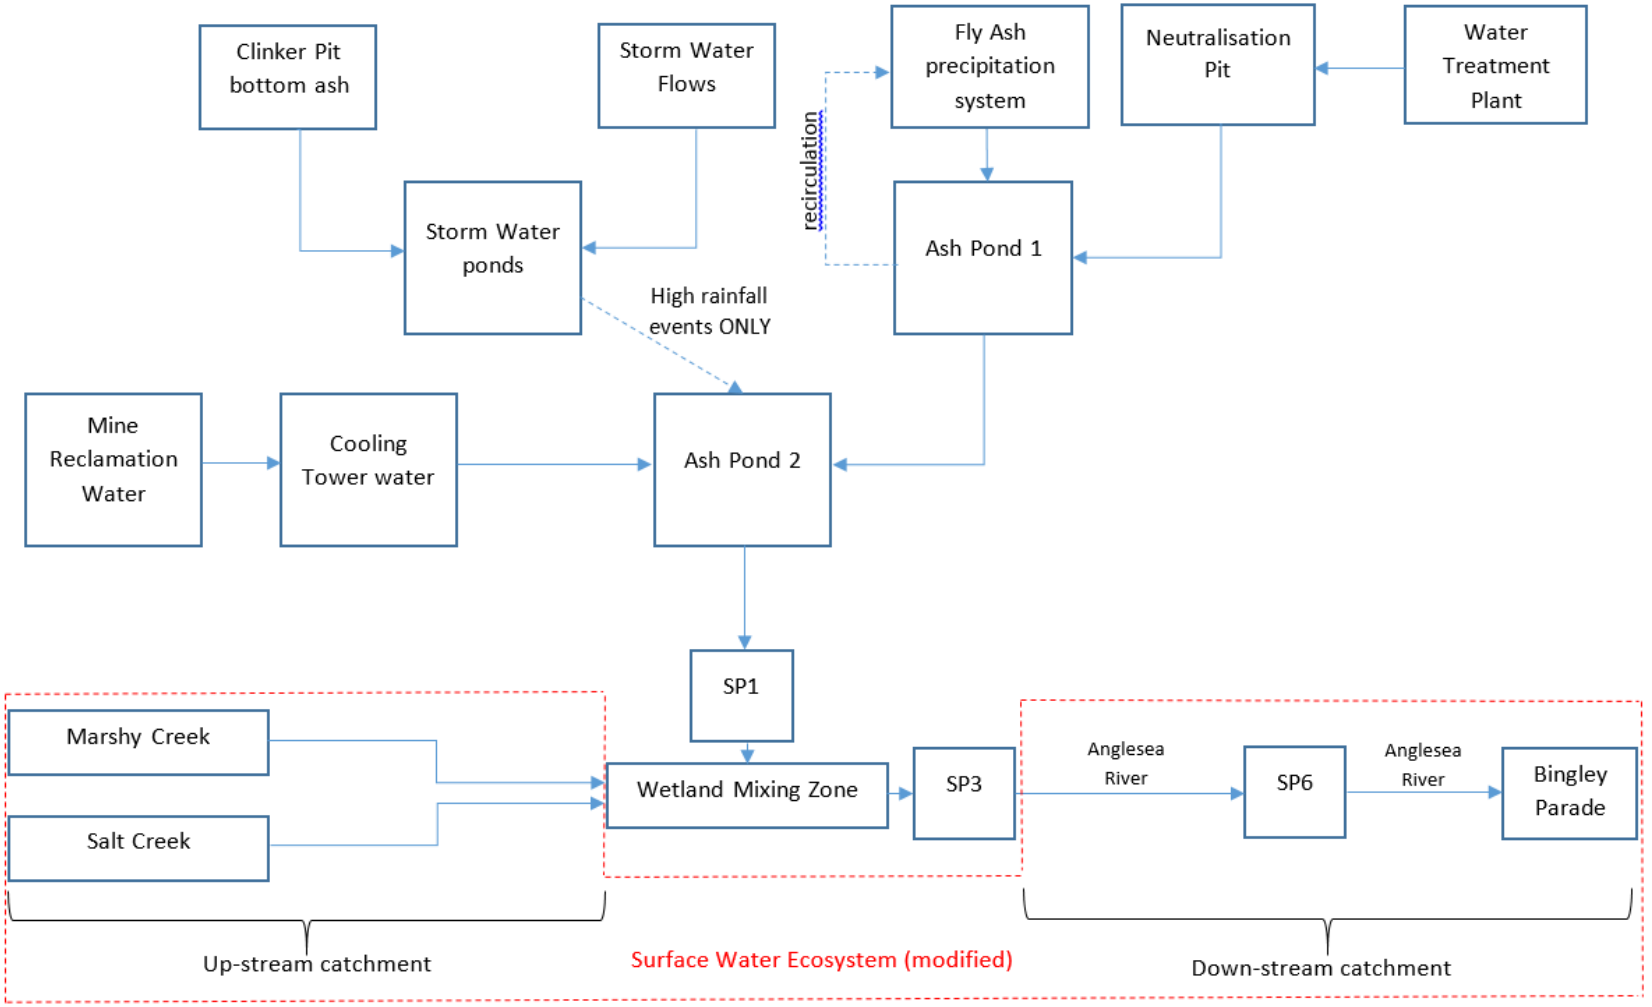

Figure 4-3 Surface Water Flow Diagram

4.2.2.2 Upper Anglesea River/Marshy Creek

Upper Anglesea River/Marshy Creek is located upstream of the former power station (upstream of monitoring point AV2) and as such the environmental values are not affected by the discharges from the site (**Section 3.2.3** for more information on licensed water discharges at monitoring point SP3).

Aluminium, boron, iron and zinc (**Figure 4-4**) within Upper Anglesea River/Marshy Creek upstream of the site permitted discharges were generally elevated. Between 2008 and 2021 the following concentration ranges were reported at AV2:

- Aluminium – 0.53 to 254 mg/L
- Boron – less than 0.05 to 1 mg/L
- Iron – 0.66 to 160 mg/L
- Zinc – less than 0.005 to 1.37 mg/L

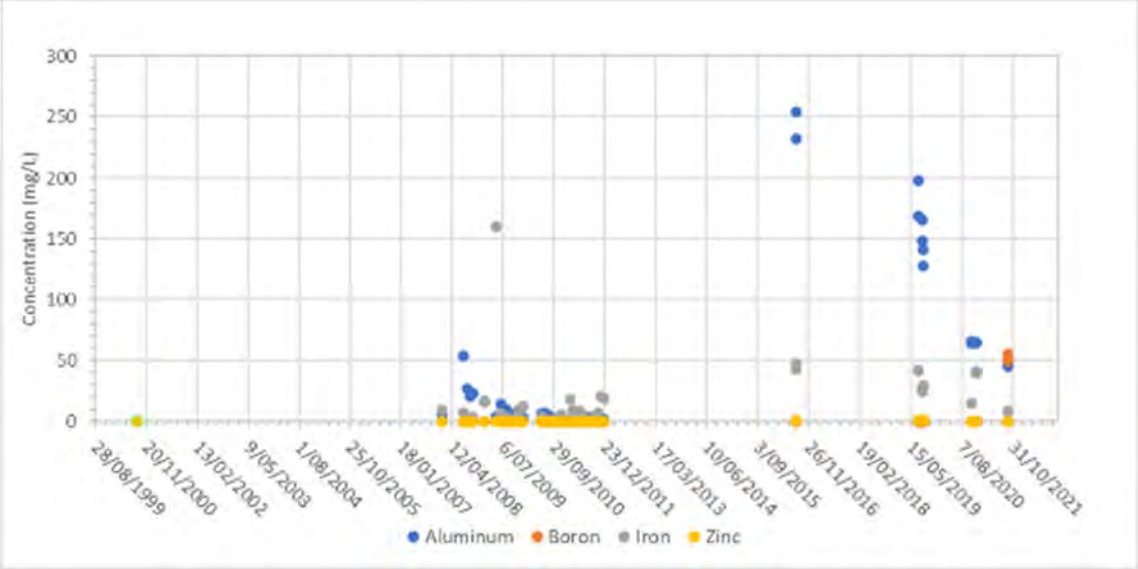

Figure 4-4 Upper Anglesea River/Marshy Creek (AV2) Trace Metal Water Quality

As shown in **Figure 4-5**, since 2009 the pH at AV2 is usually less than pH 3 (net acidic) whilst at AV1, is generally pH >5. Longer term pH data at or near location at AV2 is shown in **Figure 5-81** and also shows pH generally ranging between 3 and 4 since 1969.

The EC in Upper Anglesea River/Marshy Creek at AV1 generally ranges between 500-1,000 microSiemens/centimetre [µS/cm]) and is lower than EC measured downstream at AV2 which ranges between (2,000 and 7,000 µS/cm).

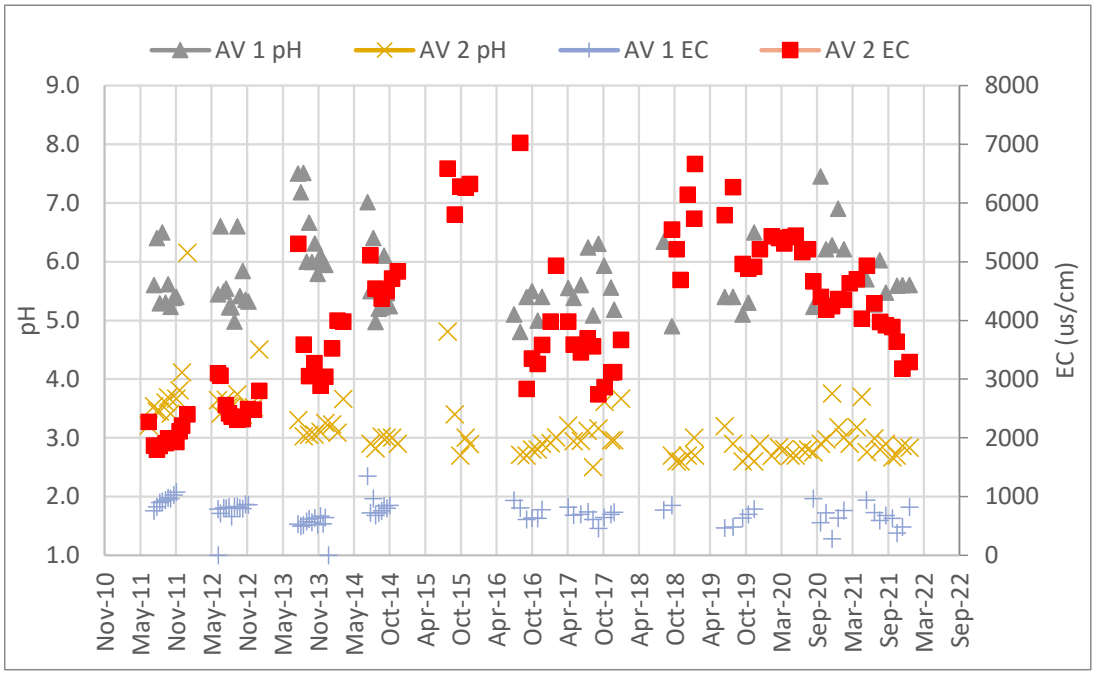

Figure 4-5 AV1 and AV2 Historical EC and pH

4.2.2.3 Salt Creek

Salt Creek is also located upstream of the former power station and as such the environmental values are not affected by the permitted discharges from the site. Aluminium, boron, iron and zinc are generally observed (**Figure 4-6**) to be elevated. Between 2010 and 2021 the following concentration ranges were reported at SV2, which is the closest upstream monitoring point on Salt Creek, to the mine:

- Aluminium – 0.16 to 306 mg/L
- Boron – less than 0.026 to 0.50 mg/L
- Iron – 0.1 to 72.7 mg/L
- Zinc – 0.006 to 3.5 mg/L

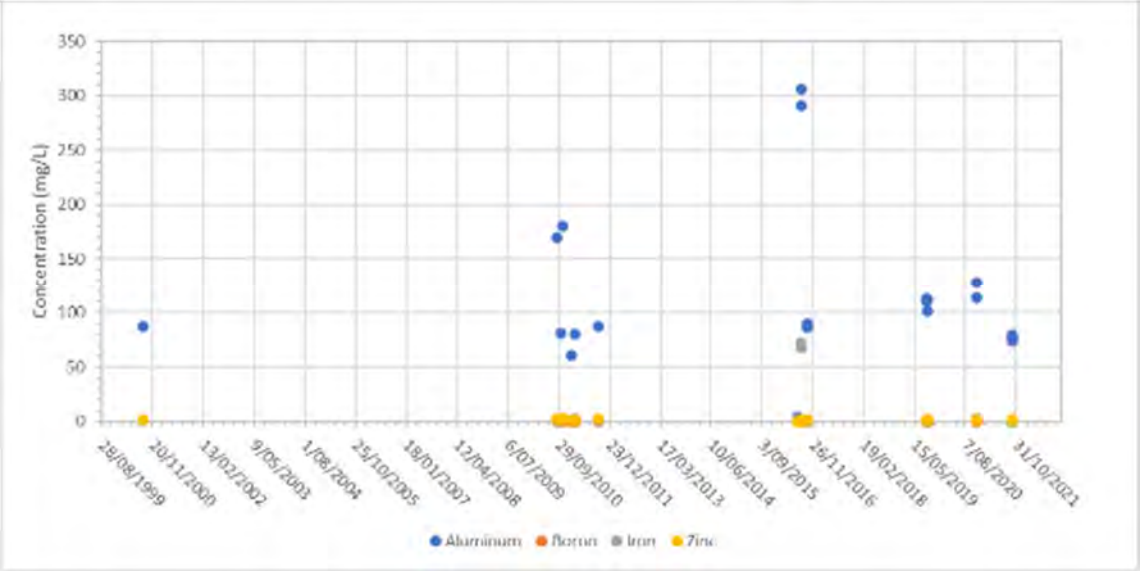

Figure 4-6 Salt Creek (SV2) Trace Metal Quality

The pH at SV2 is slightly higher than at AV2 ranging between pH 3.5 and 4. Further up the Salt Creek catchment at SV1, the pH is higher ranging between pH 5 to 7. EC at the lower end of Salt Creek at SV2 generally ranges between 250 and 2000 µS/cm), whilst in the upper part this range is more constrained varying from 250 and 2000 µS/cm. The larger variation in EC seen in the downstream part of the catchment is likely due to surface water flows being retarded in the Alluvial Aquifer and allowing evapotranspiration to concentrate salts.

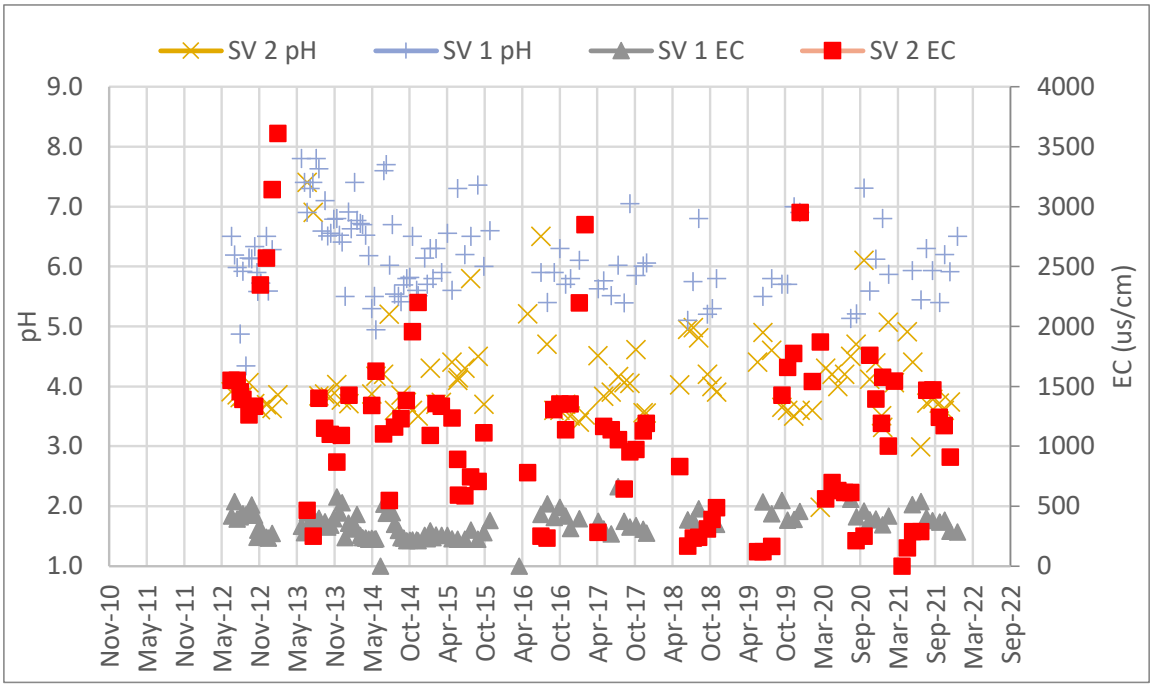

Figure 4-7 SV1 and SV2 Historical EC and pH

Table 4-4 Upstream Surface Water Quality Summary

Analyte	Units	Upper Anglesea River/Marshy Creek (AV2) (1999 – 2021)[7]					Salt Creek (SV2) (1999 – 2021)				
		Mean	Median	Low	High	90th percentile	Mean	Median	Low	High	90th percentile
pH (1970 to 1999)		3.5	3.4	2.8	7.5	4.15					
pH		3.08	2.97	2.50	6.15	3.67	4.05	3.87	1.98	7.40	4.98
TDS	mg/L	2,390	2,468	1,116	4,970	3,596	578	715	74	5,660	1,367
Aluminium	mg/L	10.8	6.2	0.53	254	151.6	47.1	87	0.16	306	176

4.2.3 Groundwater Quality

Groundwater quality (water types) for all systems is presented on a Piper plot. Within a Piper plot the two ternary cation and anion plots are projected onto the diamond plot. The diamond plot is a matrix transformation which can be used to determine varying water types. Compositionally, the majority of the groundwater samples plot as a sodium chloride (NaCl) water type (**Figure 4-8**). The dominance of this water type is most likely related to the depositional environment of the EVF (sub-littoral) and the geochemical influence on the younger aquifer sediments of the DBF and Boonah Formations. These younger sediments also indicate a sulfate influence which could be related to the oxidation and dissolution of sulfide minerals.

The salinity signatures for the Demons Bluff and Boonah Formations are not as pronounced and sulfate is more dominant. This could be potentially related to the evolution of the catchment groundwater geochemical facies along a theoretical flowline.

Groundwater within all aquifers above the LEVF is classified as Segment B, in accordance with the ERS. This is in agreement with previous classifications (Coffey, 2015; GHD, 2013). The groundwater within the LEVF is classified as Segment A2 (refer to Section 4.1 for classification of segments).

It should be noted that the TDS obtained from the historical Alcoa extraction bores shown on **Figure 4-9** generally suggest the UEVF groundwater that were reported to be within Segment A2, however and as discussed in **Section 2.3.4, Table 2-2**, many of these bores were potentially crossed screened and the water quality may have been impacted by the lower TDS groundwater of the LEVF.

The UEVF groundwater (**Table 4-5, Figure 4-9** and **Figure 4-10**) does not report significant actual acidity (median concentration of 5.8); however, groundwater may contain potential acidity. The UEVF groundwater is anoxic and in the presence of oxygen, acidity may be generated from the oxidation of ferrous iron to ferric iron. Aluminium and manganese are also reported, which could potentially produce acidity; however, zinc concentrations are below the laboratory LOR for these sample results. Providing the UEVF groundwater remains reducing, it is not considered to be a source of acidity. The reported pH does vary between UEVF locations, and it is not known whether these pH values are representative of in-situ pH or if the method of sampling has resulted in oxidation and an increase in acidity (i.e., lowering the pH).

Figure 4-10 presents the same dataset as **Figure 4-9** however as discussed in **Section 2.3.4, Table 2-2**, several older bores were decommissioned as they were likely cross screened across aquifers. Those bores are removed in **Figure 4-10.**

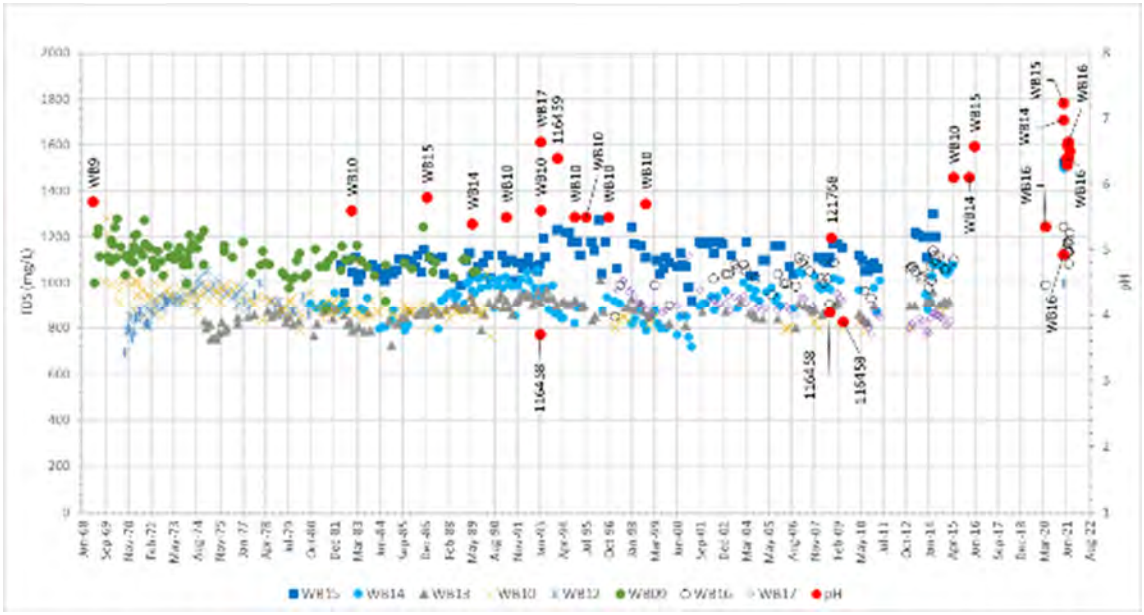

Figure 4-9 Long-Term Historical UEVF (Lower Sands) TDS and pH Trend

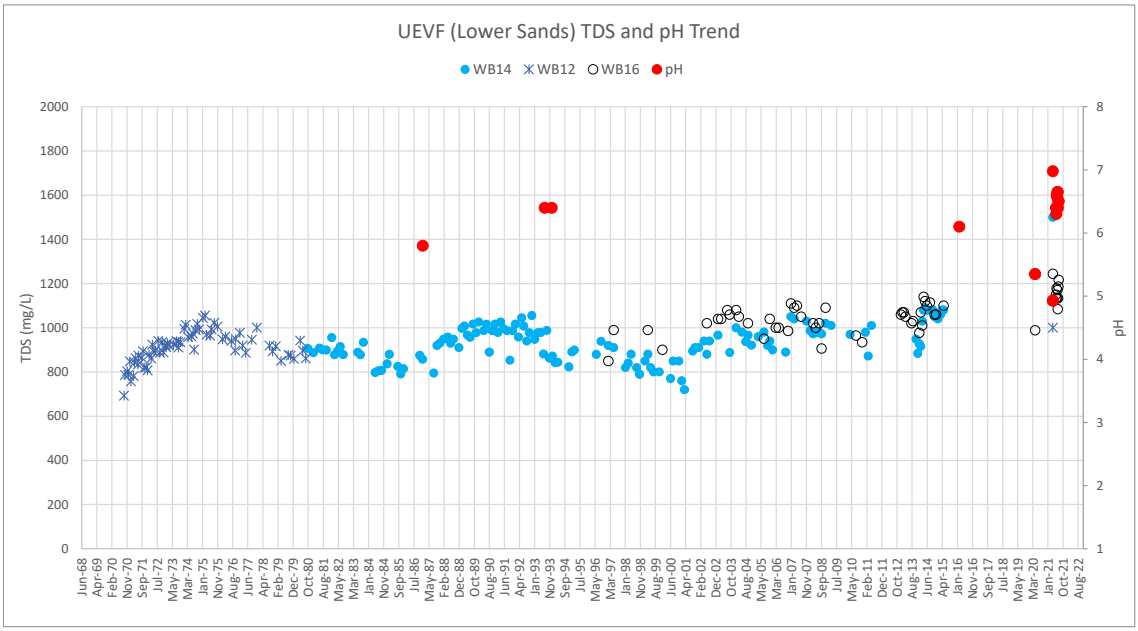

Figure 4-10 UEVF (Lower Sands) TDS and pH Trend with Decommissioned Bores Removed

4.2.3.1 Mixing Zone and underneath the Former Power Station

Water chemistry results from the mixing zone are detailed in EHS Support, 2021, Detailed Site Investigation, Alcoa Anglesea Power Station (April 2021) and EHS Support, 2021, Supplemental Surface Water, Soil and Groundwater Investigation Works, Alcoa Anglesea Power Station (April 2021). These reports were submitted and verified by the EPA appointed Environmental Auditor, Darryl Strudwick, on 29 April 2021, to fulfil obligations of Clean Up Notice (CUN 90011694). The mixing zone is disconnected from the underlying aquifers at the site; the groundwater elevations are significantly below the stream invert elevation and the groundwater level response in shallow wells during rainfall events is negligible.

In summary the results are:

- This area is highly disturbed.
- The TDS of this shallow aquifer (either the DBF or Boonah Formation) is generally consistent with Segment B groundwater (1,201-3,100 mg/L).
- Leakage from the former ash ponds, with a historic TDS of around 5,400mg/L has likely formed an artificial perched water table (PWTa) in the DBF.
- Major ion analysis shows that the Marshy Creek solid and aqueous samples are sodium sulfate in nature and appear to be in major ion equilibrium. The Mixing Zone (shallow and deep samples) are characterised as calcium sulfate.
- Ion exchange between sodium and calcium has occurred due to an influx of fresher (lower TDS) water into the Mixing Zone catchment which likely occurred during Alcoa licence discharge at SP1.

Table 4-5 UEVF Groundwater Quality Summary

Analyte	Units	Pre-Pumping Test (1999 – 2020)	During Groundwater Pumping Test (May 2021 – current)				
		Concentration range*	Mean	Median	Low	High	90th percentile
pH		3.7 – 7.2	6.5	6.5	6.3	6.7	6.6
TDS	mg/L	830 - 1313	1193	1260	741	1660	1520
Aluminium	mg/L	0.005 – 0.02	0.006	0.03	0.0008	0.03	0.02
Boron	mg/L	0.04 – 0.14	0.066	0.050	0.035	0.339	0.246
Iron	mg/L	4.2 – 63.2	16.88	19.95	0.02	63.4	60.06

mg/L = milligrams per litre
NR = Not Recorded
TDS = total dissolved solids
Water quality data from other production bores have been omitted from the statistical analysis due to bore integrity issues and have now been decommissioned. This bores WB3, WB5, WB8, WB9, WB10, WB13, and WB17
* Limited data record from 1999 to 2020 didn't allow for statistical analysis. Therefore, a concentration range is provided.

Table 4-6 LEVF Groundwater Quality Summary

Analyte	Units	(2019 Sampling, P3. P6, P9, P12, P13, P16, WTOB4 and WTOB5)		
		Median	Low	High
pH		6.23	4.59	6.92
TDS	mg/L	622	219	1200
Aluminium	mg/L	<0.005	<0.005	0.11
Boron	mg/L	#N/A	#N/A	#N/A
Iron	mg/L	13	9.8	14

5 Conceptual Geological and Hydrogeological Model

A conceptual geological and hydrogeological model (CHM) was developed using both regional and site-specific investigation data. This model builds on the previous CHM used for the development of the initial numerical groundwater flow model, specifically, the CHM defined in (GHD, 2013) and (EHS Support, 2018, 2020). The CHM forms the building block for ongoing technical support and delivery of project deliverables for Alcoa to meet the requirements set out within the MCRP as well as support the development of the updated regional numerical groundwater flow model (GHD, 2021a).

There has been a significant amount of independent work undertaken over the last 60 years to characterise groundwater behaviour. The main investigations which have significantly advanced the understanding of the hydrogeological conditions are summarised in **Table 2-3**. These reports and where available, the data, have been used to assist in building this CHM and develop the numerical groundwater flow model used to assess groundwater related risks.

5.1 Regional Geology

Regionally the site is located in the Torquay Sub-basin (**Figure 5-1**), which was isolated from the Otway Basin when the mid-Cretaceous Otway Ranges were uplifted in response to the break-up between Australia and Antarctica (Trupp *et al.,* 1994).

The Torquay Sub-basin is a northeast trending, rift depocentre that occupies largely offshore areas along the Victorian coast in the north-eastern part of the Otway Basin. It was initiated in the Early Cretaceous as a result of rifting along the southern Australian margin that culminated in the break-up of Australia and Antarctica. There are two main fault-bounded structural elements within the sub-basin, the Basin Deep ("Nerita Trough" or "Nerita Deep") and Snail Terrace. The lower part of the basin-fill comprises rift-related, fluvio-lacustrine sediments of the Lower Cretaceous Otway Group (Crayfish and Eumeralla super-sequences). The upper Torquay Sub-basin comprises Upper Cretaceous to Eocene, coal-prone fluvio-lacustrine sediments of the EVF, Eocene to Oligocene siliciclastic sediments of the DBF, and Oligocene to Miocene marine carbonates of the Torquay Group.

The mining has exposed, over a strike length of 2 km, a 20 to 35 m-thick coal seam at the base, and up to 80 m of overburden sandstone, siltstone, carbonaceous shale and minor coal. These exposures reveal the relationship between the Eocene upper units of the Eastern View Formation, the overlying Boonah Formation, and the lower units of the Salt Creek and Anglesea Formations of the DBF. The relationship between the EVF exposed in the Anglesea coal mine and the deeper stratigraphy was re-interpreted using deep aquifer drilling and age dating in the area (Holdgate *et al.,* 2002). The mine exposures also provide a record of the Boonah Formation, the Salt Creek Formation, and the lower beds of the Anglesea Formation not seen in coastal outcrops. All coal and oil exploration, groundwater and stratigraphic drilling results have been compiled. From this, the onshore basin can be structurally divided from south to north into the southeast-plunging Anglesea Syncline, the east-pitching Bald Hills Anticline, the east plunging Bells Beach Syncline. (Holdgate *et al.,* 2002).

North to south and west to east conceptual cross-sections are displayed on **Figure 5-3** and **Figure 5-4** respectively. These cross-sections (**Figure 5-2** for location) illustrate the extent of formation outcrop, deposition, and the structural controls on the geological layering. **Figure 5-5** shows a southwest–

northeast regional cross-section through the Tertiary deposits of the Anglesea area, showing stratigraphic correlations, geophysical logs, palynological ages, sequence boundaries and structures.

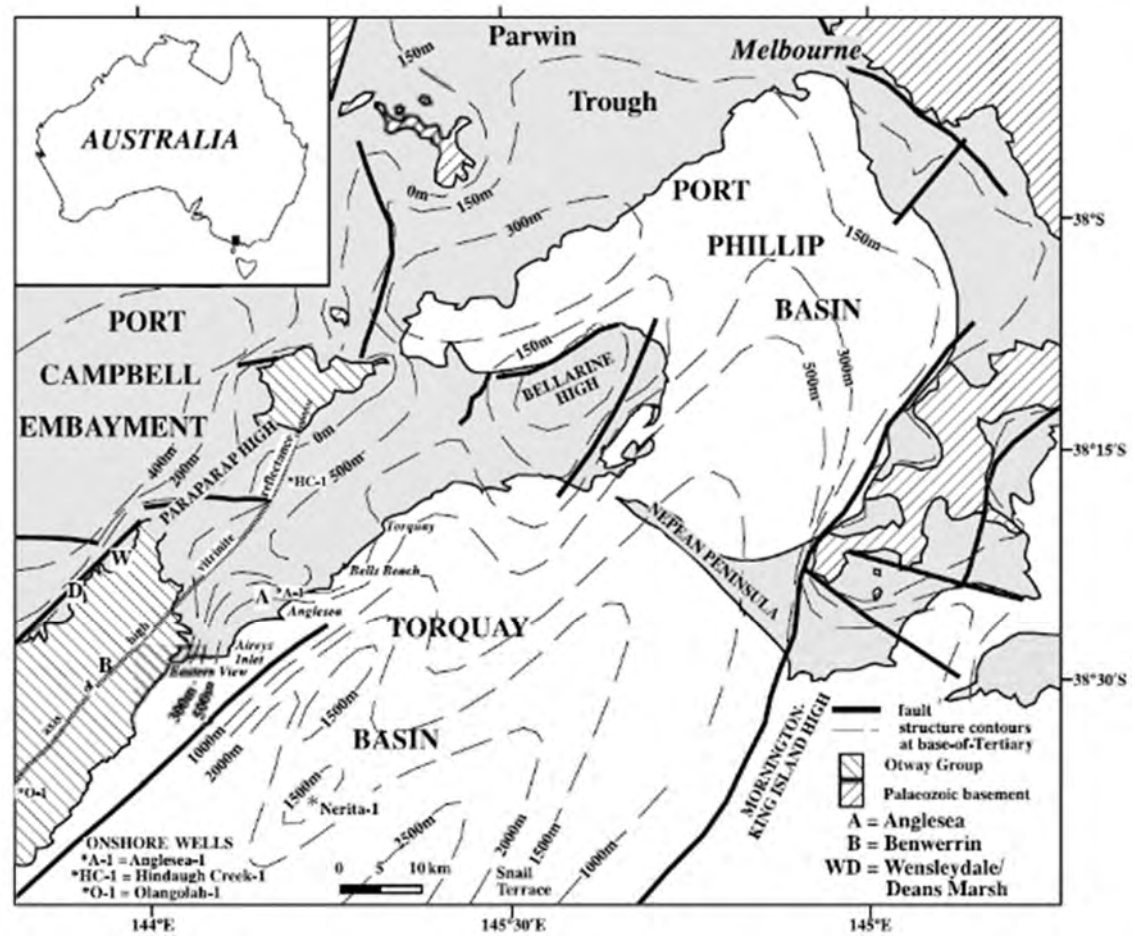

Figure 5-1 Location and Structural Map of the Central Coastal Basins of Victoria Including the Torquay Basin

Note: The main basement and Otway Group outcrops and generalised structure contours on base-of-Tertiary are also shown

5.1.1 The Boonah Formation

As shown on the stratigraphic sequence in **Figure 5-7**, the Boonah Formation is listed as a member of the Demon Bluff Group (DBG). This has not always been the case. From 1955 to 1994, the Boonah Formation was included within the Eastern View coal measures (Raggatt and Crespin, 1955) and later the EVF (Abele, 1968). This extent is shown in the Geological Survey of Victoria Anglesea 1:63,000 geological map sheet (GSV, 1967).

In (Holdgate *et al.,* 2002), the Boonah Formation was re-assigned from the EVF to the DBG. This has resulted in the DBG extending further inland, where it outcrops across the mine lease area and includes part of Anglesea River, Salt Creek and the Salt Creek diversion channel. This outcropping area is estimated and presented on **Figure 5-6** with the outcrop defined after reviewing the lithological data from bores recorded in the Geological Exploration and Development Information System (GEDIS).

As the Boonah Formation is an important geological unit within the Alcoa mine lease area, the Boonah Formation will be separated out from both the DBF and the UEVF for the purposes of numerical groundwater model development.

5.1.2 Jan Juc Groundwater Management Area

The Alcoa and Barwon Water borefields are located within the Jan Juc GMA. The Jan Juc GMA incorporates the north-western onshore section of the Torquay Basin. Within this portion of the basin, there are two distinct synclines, the Anglesea Syncline and the Bells Beach Syncline, where the sedimentary sequences are up to approximately 500 m and 350 m thick respectively. Separating the two synclines is a bedrock high referred to as the Bald Hill Anticline or the Bells Beach Anticline.

A summary of the main geological units in the region, from youngest to oldest, in the GMA, is shown in **Table 5-1** and on **Figure 5-7**. The Alcoa borefield targets the permeable sand lenses of the lower part of the UEVF, while the Barwon Water borefields target the permeable sand lenses of the LEVF. A series of regional north to south and west to east cross-sections illustrate the stratigraphic sequence relationships. The cross-section locations are shown on **Figure 5-8** and the cross-sections are presented on **Figure 5-9** to **Figure 5-15**. In addition to the investigation and observation bores drilled by Alcoa and Barwon Water, these cross-sections were developed using publicly available data, and were obtained from the following sources:

- GeoVic layers (earthresources.vic.gov.au).
- Discover and access Victorian Government open data | Data Vic.
- Visualising Victoria's Groundwater (vvg.org.au).
- Geological Exploration and Development Information System (GEDIS) (vvg.org.au).

Table 5-1 Geological Units Across the Jan Juc GMA

Period	Geological Unit	Description	Approximate Thickness
Quaternary	Swamp and Alluvial Sediments	Alluvium consisting of sand, silt, clay and gravel deposited along the local river valleys and swamp deposits such as peat in the main swamplands.	Generally, 10 -30 m thick. Present along the creek lines (i.e., Painkalac Creek, Salt Creek, Spring Creek and Anglesea River), and thickest in the Salt Creek Swamp and Anglesea Swamp.
	Colluvium	Sand, silts and clays	Also present along some creek lines.
Tertiary	Moorabool Viaduct Sands	Sand, ferruginous sand, limestone and gravel, and was deposited in a marine environment	Also present along some creek lines.
	Torquay Group (including Jan Juc and Puebla Formation):	limestone, marl, calcareous and clayey silt, deposited in a marine environment	This unit is mainly present to the northeast of the Torquay Basin and overlies the Demons Bluff Formation.
	DBF	Marine deposit of fine-grained micaceous and carbonaceous silts and silty clays.	Along the coastal stretch between Aireys Inlet and Anglesea and stretches inland towards the Bells Beach anticline.

Period	Geological Unit	Description	Approximate Thickness
	Boonah Formation	As discussed in **Section 5.1.1** The Boonah Formation has historically been reported to be a member of both the UEVF (upper most unit) and the DBF (lower most unit). The formation consists of 1-3 m thick- coarse-grained sand-channel units with interbedded minor clay, shale and carbonaceous siltstone.	In the Anglesea coal mine, the Boonah Sands Formation is up to 32 m thick with the permeable sections extending laterally up to 50 m (e.g., representative of disconnected "shoe-string sands").
	EVF	Deposited in a non-marine lacustrine or deltaic environment and subdivided into three distinct units	Unit up to 250 m thick in Anglesea Syncline. Coals from this unit were formerly mined by Alcoa (generally <50 m thick).
	UEVF	Clay, silty clay, silt and fine to medium grained sand sequences with minor fine gravel lenses. Brown coal seams are common in the top of the sequence.	
	MEVF	Clay, silty clay, shale and mudstone.	In the order of 50-60m deep in the Anglesea Syncline and 25-50 m thick in the Jan Juc syncline
	LEVF	Micaceous silts, carbonaceous clays, silty clays, thin brown coal and fine to coarse grained sands and gravels.	The average thickness of the unit is almost 450 m along the Anglesea Syncline and 100 m along the Jan Juc Syncline
Lower Cretaceous	Otway Group	Inter-bedded sandstones and laminated grey siltstone and mudstone	The bedrock outcrops on the western side of the GMA, and along the Breakfast Creek Tributary gully.

DBF = Demons Bluff Formation
EVF = Eastern View Formation
GMA = Groundwater Management Area
LEVF = Lower Eastern View Formation
m = metre
MEVF = Middle Eastern View Formation

5.2 Local (Alcoa Area of Interest) Geology

5.2.1 Area of Interest Overview

The Alcoa Area of Interest (AOI) is a region within the broader catchment and numerical groundwater model domain (GHD, 2021a) that has been broadly defined by geological characteristics as well a conservative analytical radius of influence (defined by the Hantush-Jacob equation) associated with pumping bore on the former Alcoa Power station site at a rate of 40 l/s. The adopted hydrogeological parameters have been derived from the pumping test **Appendix D**.

The Hantush-Jacob solution is defined as:

$$s = \left(\frac{Q}{4\pi T}\right) w(u, \frac{r}{B}); \quad u = \left[\frac{(r^2 S)}{(4Tt)}\right]; \quad B = \sqrt{\left[\frac{Tb'}{K'}\right]} \tag{3}$$

Where s is drawdown [m], b' is aquitard thickness [m], K' is vertical hydraulic conductivity of the aquitard [m/d], Q is pumping rate [l/s], r is radial distance from pumping well to observation well [m], S is storativity [-], t is elapsed time since start of pumping [days] and T is transmissivity [m²/d].

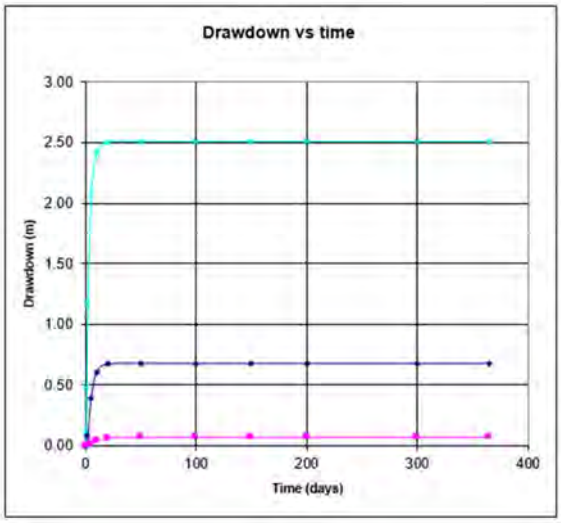

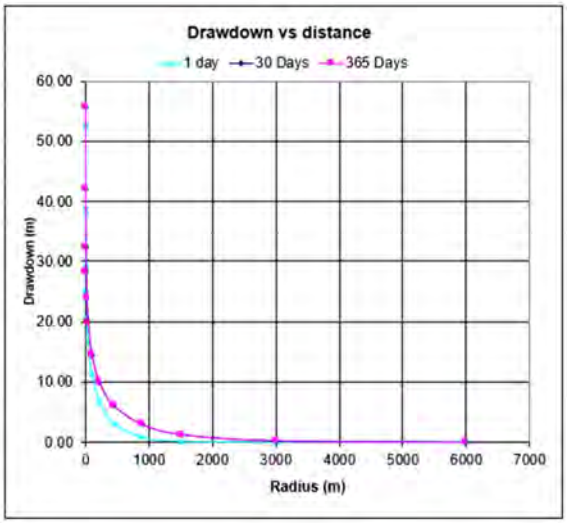

Figure 5-16 Analytical Drawdown Results

The results (**Figure 5-16)** suggest a 3km radius of impact. The AOI also takes into consideration the geological features of the northern boundary (basement high) located approximately 4 km from the pumping bore (WB16). Edwards Creek, a tributary of the Upper Anglesea River, is also located at the northern edge of the AOI. The western boundary is located approximately 4km from WB16. This location is close to Scrubby Hill and where the Bells Beach Anticline causes the entire EVF sequence to thin. The southern margin is defined by the coast, located approximately 3km from WB16. The western extent is defined at the contact boundary between the UEVF and MEVF. This location is also west of the Anglesea syncline, which is approximately 6 km from WB16.

Beyond the extents listed above, based on geology (the maximum rate that bore WB16 can efficiently pump (e.g. ~40 l/s) and empirical groundwater equations, it is unlikely that any proposed groundwater pumping activities will have (or can have) an impact on groundwater systems or other environmental assets.

The key features (**Figure 1-1** and **Figure 2-2**) within the AOI include:

- The mine pit void.
- The former power station monitoring and pumping bores (including WB16).
- The Anglesea River estuary and lower marshlands associated with the Anglesea River.
- Salt Creek diversion and a portion of the Salt Creek marshland.
- Barwon Water southern borefield (GW1 to GW5).
- The township of Anglesea.

5.2.2 AOI Geology

This section discusses in greater detail the local geology/stratigraphy in the Alcoa AOI. **Figure 5-17** shows the upper 50 m beneath the mine to better understand the location of each unit. The deeper stratigraphy immediately below and surrounding the mine within the Alcoa AOI is shown in cross sections on **Figure 5-18** to **Figure 5-23**.

5.2.2.1 DBF (Anglesea Formation, Salt Creek Formation and Boonah Formation)

At the Anglesea mine, the following members of the DBF are present:

- Anglesea Formation.
- Salt Creek Formation.
- Boonah Formation.

The contact between the units above is shown in **Figure 5-25**. Each unit is described in detail below.

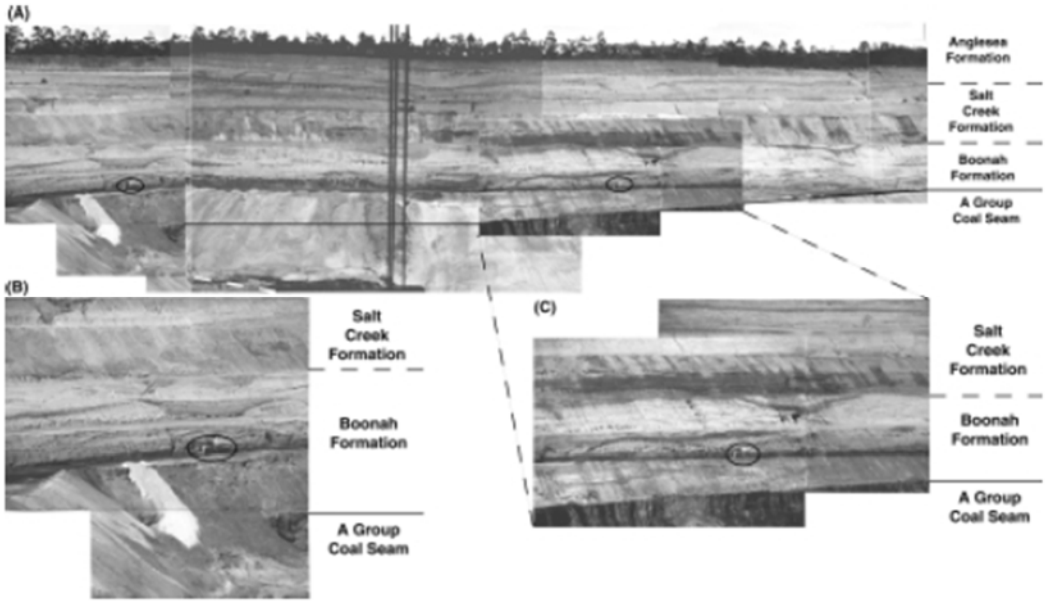

Figure 5-25 Contact Between DBF Units

Notes: Detailed (a) Composite photograph of the coal and highwall succession at the Anglesea coal mine and interpreted formation boundaries and lithostratigraphic units. (b) Channel structures and disconformity between the Boonah Sands Formation and the overlying Salt Creek Formation. (c) Channel structures, coaly units and disconformity between the Boonah Sands Formation and overlying Salt Creek Formation at the central part of the mine. Note 4.5 m-high dump trucks (circled) for scale
Source: after Holdgate et al., 2002.

5.2.2.1.1 Anglesea Formation

The upper highwall succession in the Anglesea coal mine comprises up to a 20 m-thick red to purple carbonaceous and pyritic siltstone to fine sandstone. The Anglesea Formation is interpreted to represent a complex of low-energy fluvial channel and braided sheet-like sands deposited on a lower coastal plain, which periodically became higher energy channel-like with increased downcutting into earlier deposits. At least one short-duration marine flooding event (preserved as pyritic shale containing marine dinoflagellates) followed the infilling of the basal downcut surface. The remaining facies preserve low-energy fluvial channel and braided sheet-like sandstone and shale-filled meander loops.

5.2.2.1.2 Salt Creek Formation

The Salt Creek Formation is on an erosional contact that can be linked across the mine face as a series of stratigraphically connected sandstone channels. The disconformity contact is a 0.1 m shale layer between cross-bedded micaceous fine quartz sandstone of the top Salt Creek Formation below, and the homogenous micaceous fine quartz sandstone of the overlying Anglesea Formation. Other more localised low-angle channel forms occur at the bases of overlying units, such as at samples shown on **Figure 5-26** where pervasive limonite cements form ferricrete layers in the coarser grained channel bases. Red limonite staining appears to increase rapidly over the top 5 m of the member and is associated with weathering from the present ground level. Interbedded carbonaceous shale and laminated siltstone units immediately overlie the basal channel layers and form a 5 to 7 m-thick unit along the mine face. The basal silty shale of this unit is pyritic and contains evidence indicative of a short-duration marine transgression.

5.2.2.1.3 Boonah Formation

Unconformably overlying the A Group coal seam (main Coal Seam) in the Anglesea coal mine, and in nearby bores, are clean sandstone with minor carbonaceous shale, clay and coal. Down dip the sandstones increase from 10 m to 70 m in thickness. These sediments belong to the Boonah Sands Formation (Holdgate 1996; Smith 1998). The basal coarse channel gravels and sandstones overlie the A Group coal seam at an erosional angular unconformity. The unit is thickest in the Anglesea Syncline, it thins to the northeast and southwest outside the synclinal area. The unconformity surface defines the upper boundary of the EVF. Due to this unconformity, the Boonah Sands Formation is placed in the DBF rather than the EVF.

In the Anglesea coal mine, the Boonah Formation is up to 32 m thick. It comprises fine to coarse-grained sand-channel units in the upper and lower 10 m, with interbedded shale and carbonaceous (leafy) siltstone occurring in the middle 10 to 12 m (**Figure 5-26**). The basal coarse facies is exposed mainly in the central part of the Anglesea Syncline and onlap the top of the A Group coal seam to the west.

Cross-cutting, fining-upward channel units range between 1 m and 3 m thick and extend laterally from 30 m to 50 m. Finer grained overbank deposits are poorly represented, but where preserved, consist of planar-laminated carbonaceous siltstone.

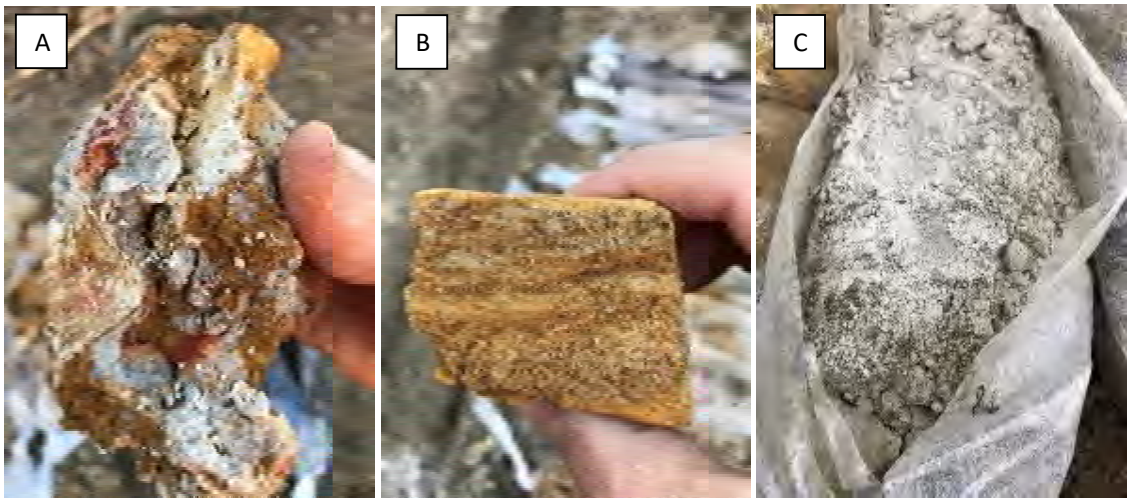

Figure 5-26 (a) Salt Creek Formation, (b, c) Boonah Formation

Note: refer **Figure 5-27** for full profile

5.2.2.2 Eastern View Formation

The following section is an adaption of Holgate *et al.,* 2002, as well as site observations.

The EVF comprises a largely non-marine to paralic succession of brown coal, shale and sandstone that is over 500 m thick at the core of the Anglesea Syncline. The EVF thins to the north and northwest over the Paraparap and Bellarine Highs. Offshore in Nerita 1 well, the group (Eastern View Coal Measures in the *Well Completion Report*, Shell Development, 1967) is 683 m thick. It is overlain by a 141 m-thick Boonah Formation that is separated from the EVF on seismic by an angular unconformity.

Most of the significant coal seams of the EVF occur in the upper parts of the Formation. This is interpreted to be the UEVF,(**Section 5.2.2.2.1** to **Section 5.2.2.2.4**; **Figure 5-27**). In the Anglesea area, the coal seams are folded by the Anglesea Syncline, the axis of which plunges south below the Anglesea township into the offshore Torquay Basin (**Figure 5-29**). The mining of the coal seams occurs northwest of the township in the up-dip direction, where the seams are shallowest (**Figure 5-29**). The uppermost and thickest A Group coal seam is up to 36 m thick (**Section 5.2.2.2.1 Main Coal Seam**) and locally splits near the base into the A1 and A2 seams.

Below the A Group coal seam in the Anglesea mine area is up to a 20 m-thick coarse sandstone and minor claystone interval (**Section 5.2.2.2.3 Upper Sands**). Beneath this unit for 60 to 70 m are a series of 2- to 15-m-thick B Group coal seams interbedded and laterally equivalent to shale and sandstone (**Section 5.2.2.2.4 Intermediate Coal and Clay**). These seams were mined in the 1950s on the western flanks of the Anglesea Syncline in two Roche Brothers' open cuts but are not exposed today (**Figure 5-29**).

The oldest C Group coal seams are separated from the B Group coal seams by a 10 to 15 m interval of fine sandstone and silty claystone that appear, on bore log cross-sections, to separate the two groups at a local disconformity (Holdgate, 1996). The C Group coal seams include a 20-m-thick seam at the top (the C1), which is best developed on the western flank of the Anglesea Syncline. In turn, C Group coals overlie a series of interbedded thin coal (<5 m thick), sandstone and shale over a stratigraphic interval of 60 m.

Below the C Group coal seams a 100-m-thick interval of interbedded sandstone and shale overlies a 250 m succession of thick mudstone with coarse sandstone, over Otway Group arkosic sandstone (**Section 5.4.5 LEVF**). To the north of the mine, the Anglesea Syncline merges against the prominent east-plunging Bald Hills Anticline. This anticline is interpreted to outcrop at the coast at Jarosite Headland, where it is expressed as a low-angle fold in beds of the DBF.

The Otway Group was intersected near Jarosite Headland at 135 m in WRC-121768 bore, overlain by 55 m of the Eastern View Group (mostly comprising the B Group seams and inter-seam sediments). In State Observation Bore (SOB) 121768 near the Bells Beach Anticline, only the B and C Group coal seams are present beneath towards 40 m of mid to lower EVF and 80 m of DBF.

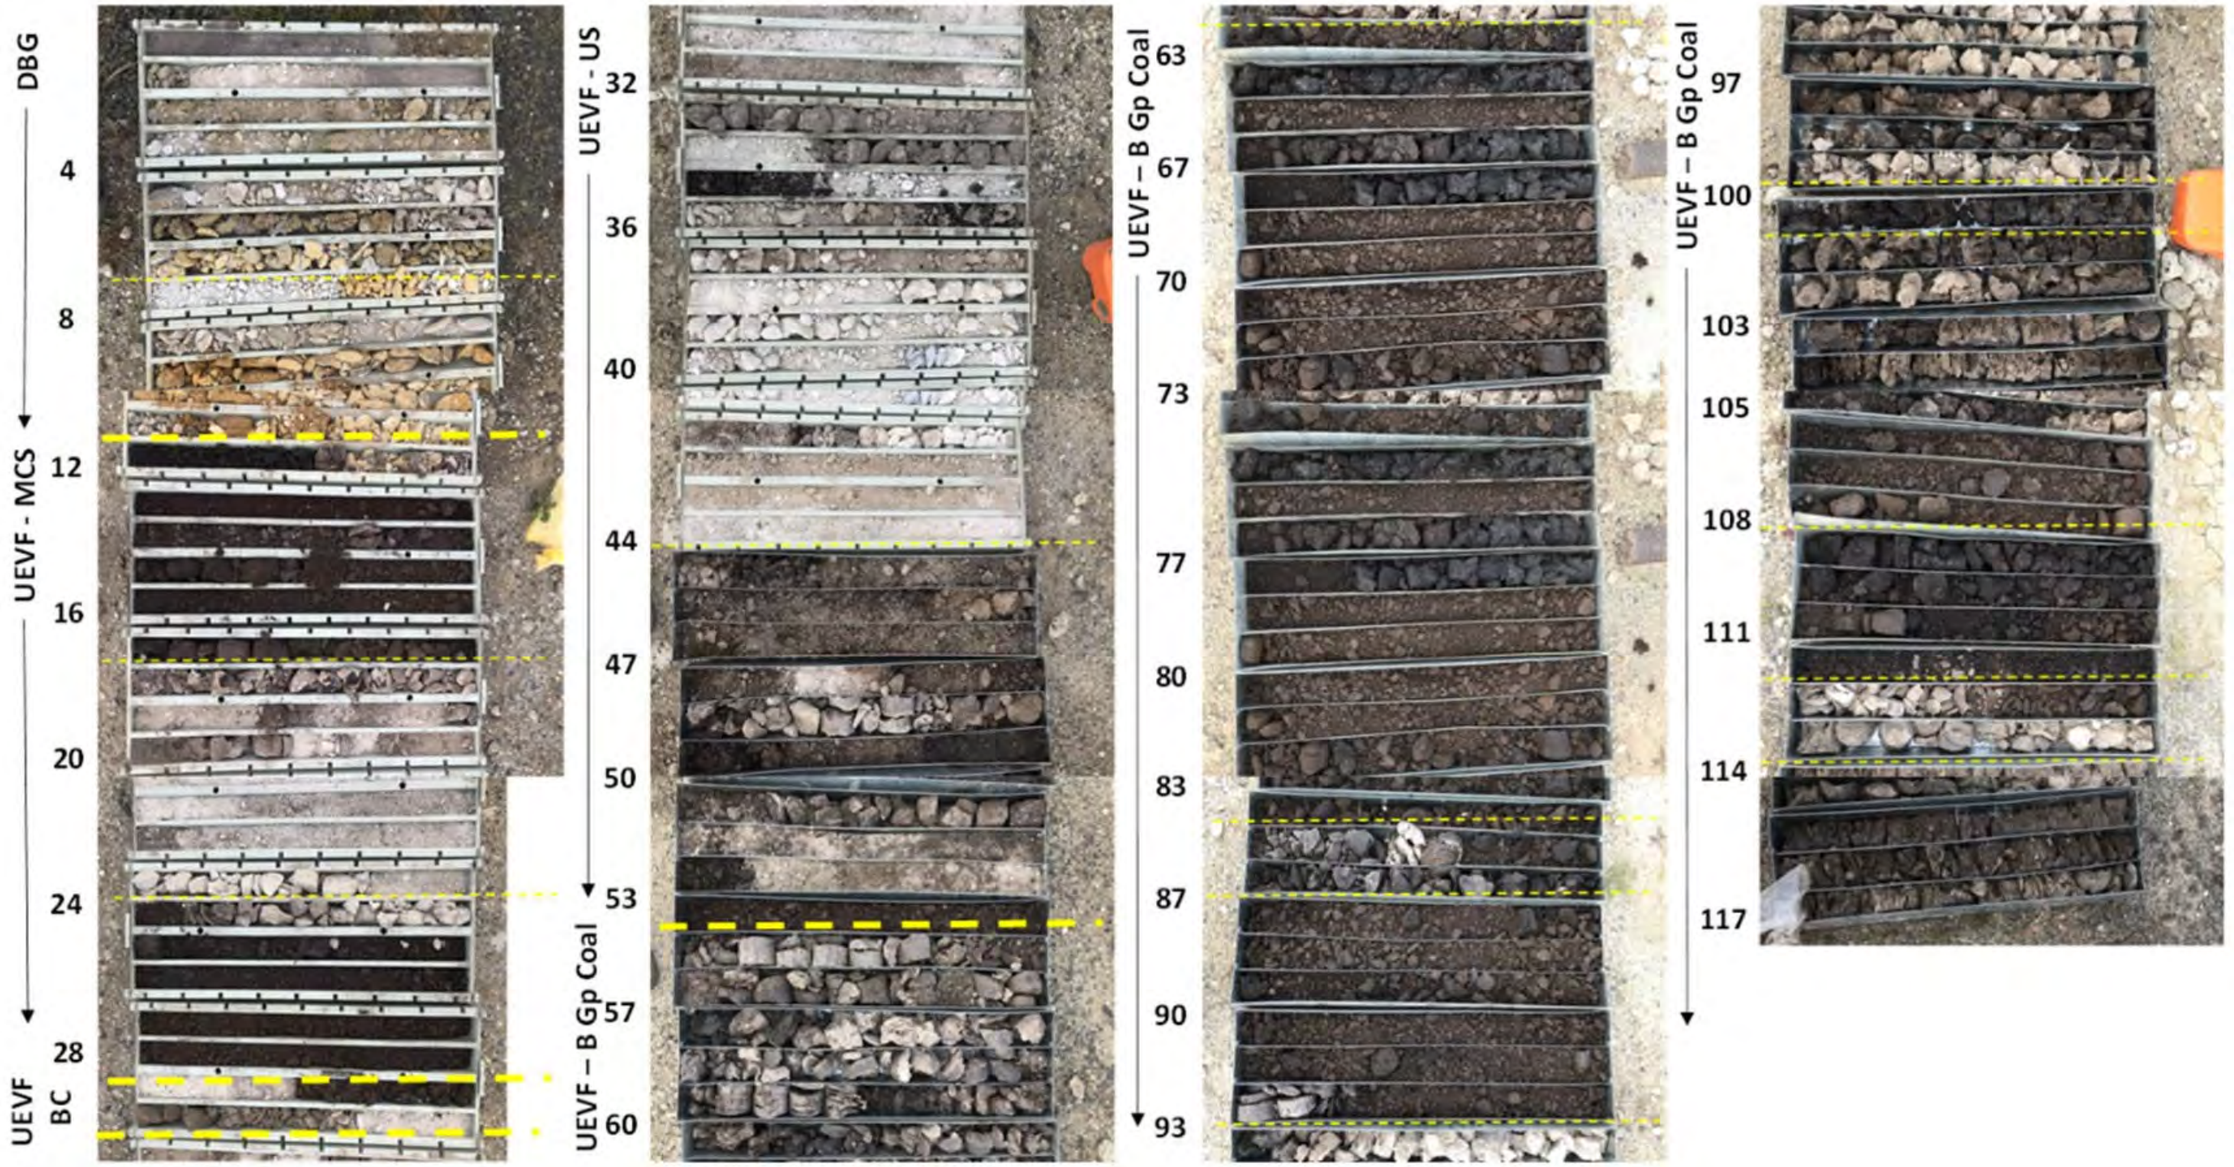

Figure 5-27 UEVF MB 7 Core

Notes:
MCS = Main Coal Seam
BC = Basal Clay

5.2.2.2.1 Main Coal Seam

The main coal seam, also referred to as “coal seam A or A Group coal seam” consists of brown coal and does not outcrop (**Figure 5-29**). At its thickest, the main coal seam is up to 45 m thick, and this occurs near the mine and Anglesea Syncline. This unit is not to be confused with other major coal seams within the UEVF sequence. Those coal layers below the main coal seam can be referred to as Seam B1/L1, B2/L2, B3/L3 etc and are more consistent with ligneous coal.

The extent of the formation (sub-crop) is shown on **Figure 5-34**.

Figure 5-28 Site Photo Showing the Main Coal Seam Exposure and Core Representation

Note: looking northwest from mine pit surface water sampling location

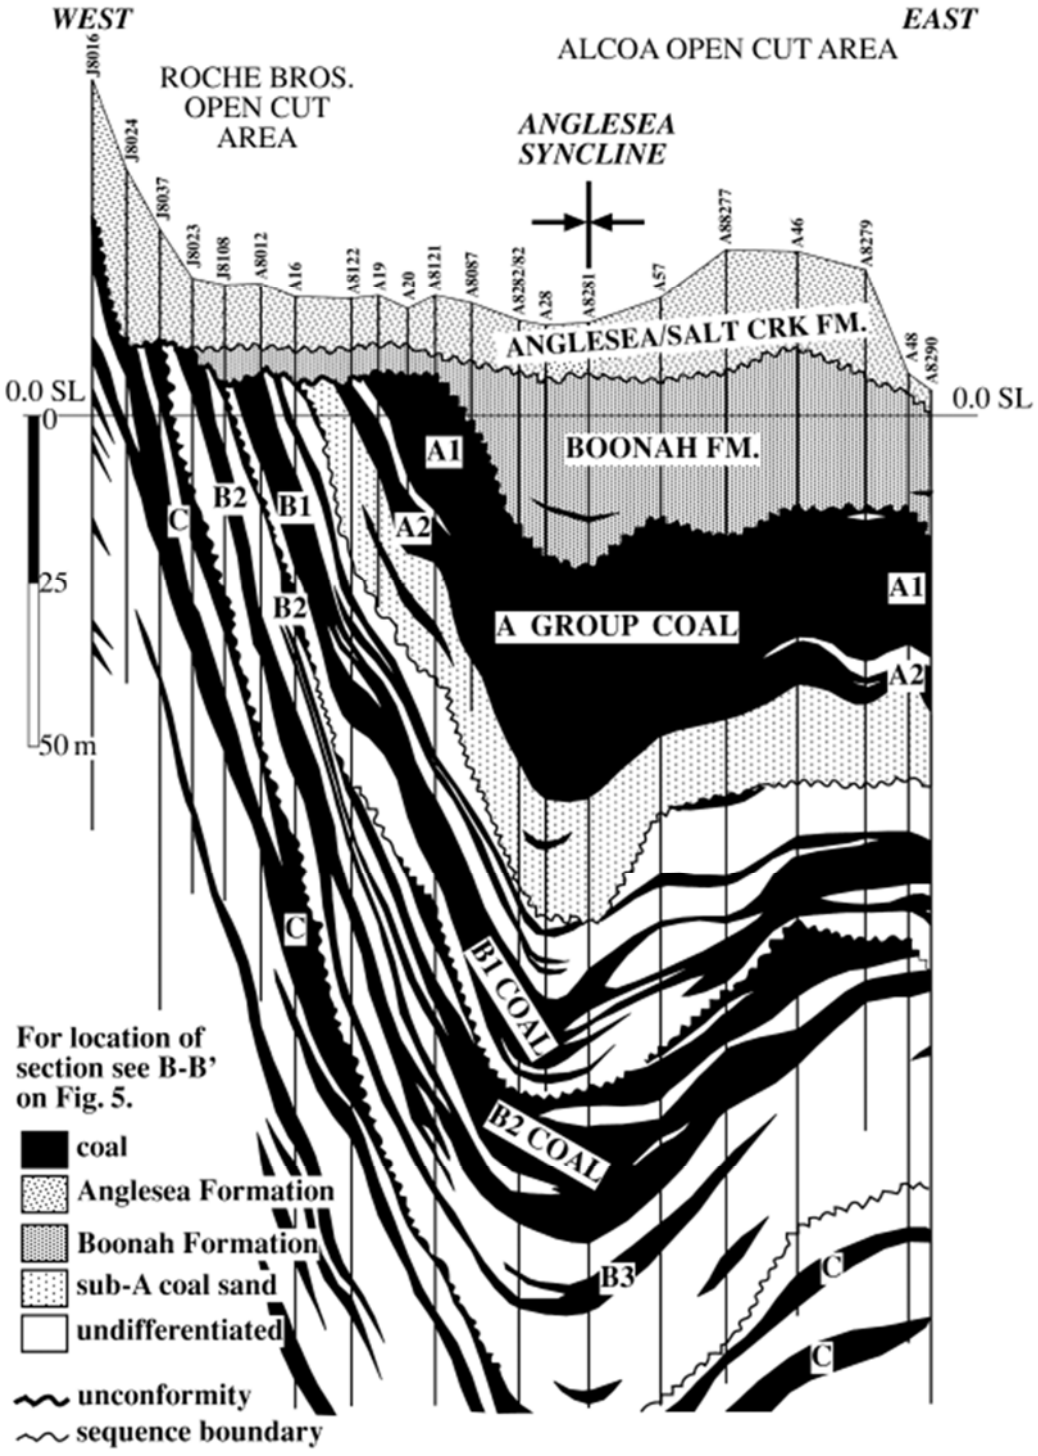

Figure 5-29 EVG Coal Seams

Source: Holdgate et al., 2002

5.2.2.2.2 Basal Clay

The basal clay consists of a low permeability grey to pale brown clay layer (**Figure 5-30**) and is located immediately below the main coal seam. The thickness of this clay varies from 1 to 4m has been derived from the databases listed in **Section 5.1.2,** and lithological logs from those bores presented in **Figure 5-8**. Where lithological logs do not describe the colour, the clay that is immediately below the main coal seam was allocated as the basal clay. Further information on the Basal Clay is discussed in **Section 5.4.3.1**.

Figure 5-30 Field Picture of the "Confining" Clay at the Base of the Coal

5.2.2.2.3 UEVF - Upper Sands

The upper sands of the UEVF are primarily found underneath the basal clay in the vicinity of the former mine and potentially extend towards the coast. **Figure 5-29** refers to these as the sub-A coal sand. After review of the bore logs shown in **Figure 5-8** and the geological cross section (**Figure 5-18** to **Figure 5-24**), the upper sands do not outcrop or extend in any great distance west and north of the mine, rather they pinch out within the subsurface. In bore log UEVF MB08 on the western margin of the mine, these sands were not encountered. These sands may also be referred to as "shoestrings sands" (i.e., an irregular, sinuous and variable thickness sand-body which often represents the preserved sandy deposit of a meandering river channel).

The thickest this unit is observed is 25 m and varies from 0.5 m to 25 m with a typical thickness being less than 5 m where the unit occurs. As mentioned above, these sands do not outcrop with the shallowest section identified at 22 m bgl. This occurs near UEVF MB07. **Figure 5-31** shows a sonic drill core section of these sands.

The extent of the formation and its outcrop area are shown on **Figure 5-35**.

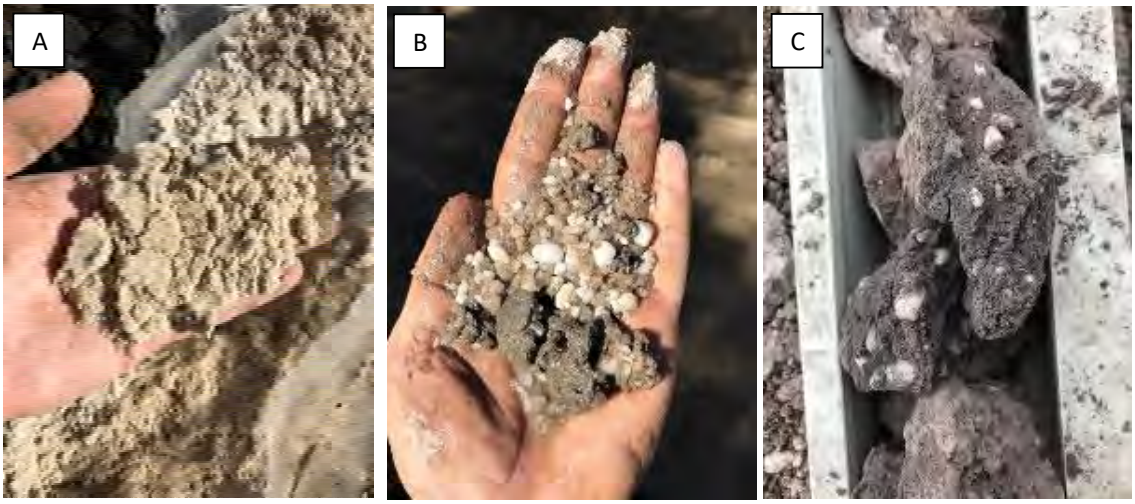

Figure 5-31 (a) Top of Unit, (b) Mid Unit, (c) Base of Unit

5.2.2.2.4 UEVF - Intermediate Zone

Below the A Group coal seam and the UEVF upper sands a series of peaty coal and tight clay that extends a further 60 to 150 m. Each sequence of coal and clay vary in thickness of between 2 to 30 m. The coal sequence are interbedded and laterally equivalent to shale and fine sandstone. The upper coal seams were mined in the 1950s on the western flanks of the Anglesea Syncline in two Roche Brothers' open cuts but are not exposed today. **Figure 5-32** shows what these coals and clays look like as well as a cracked drill bit resulting from the tightness of the formation and over torque required to progress. The outcrop area is shown on **Figure 5-6**.

Figure 5-32 UEVF Intermediate Coal (a) and Clay (b), Cracked Annular Steel Tooth Drill Bit (c)

Very occasionally a thin (<20cm) seam of coarse sand and gravel is encountered (**Figure 5-33**) in this sequence. In order to define the extent and hydraulic properties of these sand and gravel lenses, a single packer test was attempted over this interval. After ~250L of water was injected, the packer failed indicating some upper sand lenses may not be laterally extensive.

Figure 5-33 Packer Testing of 20cm Gravel Lens at 58m bgl (UEVF MB07)

5.2.2.2.5 UEVF – Lower Sand

The lower section of the UEVF comprises thicker and more frequent occurrence of thick coarse sandstone, with minor claystone and coal intervals. The total thickness is up to 180 m. No core return imagery is available for this lower sands unit. The outcrop area is shown on **Figure 5-6**.

5.3 Regional Hydrogeology Overview

The regional hydrogeology comprises four main hydrogeological units:

- The alluvial swamp aquifer (previously identified as a perched water table).
- The shallow unconfined DBF aquifer.
- The confined lower sands of the UEVF aquifer utilised by Alcoa.
- The deeper confined LEVF targeted by Barwon Water.

An overview of the hydrogeological setting for each of these three units is provided below, with further discussion on groundwater level trends provided in **Section 5.4** to **Section 5.6**.

A conceptual model of the regional hydrogeology is shown in **Figure 5-36**.

5.3.1 Alluvial Swamp Aquifer (also referred to as a Perched Aquifer)

In the Anglesea River and Salt Creek valleys, younger alluvial deposits overlie the regional aquifer systems (**Figure 5-37**). At the min and lower ends of the catchments, these sediments can be in the order of 30 m in thickness and referred to as the alluvial swamp aquifer (ASA). This ASA (previously referred to as a perched aquifer or PWT), supports the large swamplands is also located within the alluvial deposits. It is noted that along these valleys, the alluvial deposits are separated from the underlying DBF and UEVF by up to 60 m of low permeable coal and clay sequences, in affect isolating these shallow PWT systems from the deeper more permeable parts of the UEVF and LEVF.

The conceptualisation of these alluvial systems is shown on **Figure 5-36** and **Figure 5-70** to **Figure 5-77**. Furthermore, **Figure 5-37** presents the actual thickness of low permeability coal and clay that separates the base of the alluvial / swamp sediments in which surface water flows to the next most permeable layer underlying the surface water systems. The average thickness from all bores shown on **Figure 5-37** is 27.7 m with the maximum depth being 86m and the minimum thickness 2.4m.

5.3.2 Demon Bluff Formation and Boonah Formation

The Demon Bluff Formation (DBF) includes the Salt Creek Formation, the Anglesea Formation, the Addiscot Formation and the Angahook Formation (Holdgate, et al., 2001). In the greater Anglesea region, only the Salt Creek Formation, the Anglesea Formation are present.

The Boonah Formation is also present in the area and forms the base of the Demon Bluff Group and overlies the upper eastern view formation at an erosional angular unconformity (Holdgate, *et al.,* 2001). The formation is distinctly different from other members of the DBF and comprises cross cutting coarse-grained sand-channels in the lower and upper units, with shale and carbonaceous siltstone interbedded with lenses of fine-grained sandstone (Holdgate, *et al.,* 2001). The Boonah Formation is well exposed at the Alcoa Coal Mine and is expected to have highly variable aquifer properties.

Bore yields from the DBF are generally less than 0.5 litres/second (L/sec) and water quality generally exceeds 4,000 mg/L TDS. Groundwater conditions at the Alcoa Mine indicate that the DBF and Boonah Formation are largely unsaturated and discreet perched aquifers are common. These perched systems are mosty caused by leaky mine infrastructure (e.g., the former Ash ponds and other artificial water retention areas).

5.3.3 Eastern View Formation Overview

Hydrogeologically, the eastern view formation (EVF) can be sub-divided into three main units;

- Upper EVF.
- Middle EVF.
- Lower EVF.

In the Alcoa AOI, the UEVF is considered to be an unconfined to confined aquifer, the MEVF an aquitard and the LEVF a confined aquifer. Broadly speaking, these water-bearing zones approximately represent the individual aquifers within the EVF. However, sand aquifers occur at all levels in the sequence with potentiometric pressures increasing with depth, which means that

multiple permeable zones, that may or may not be interconnected may exist within the one formation. **Figure 5-3** and **Figure 5-4** show a cross-sectional relationship of each formation from the ranges to the coast.

5.4 Alcoa Area of Interest Hydrogeology

Figure 5-38 shows an overview of the hydrogeological units within the AOI. The groundwater level trends and hydrogeological parameters for each of the defined units within the AOI is further described in the sections below.

5.4.1 Alluvial Swamp Aquifer Overview

Close to the coal mine and former power station, the ASA exists within marshy creek and salt creek and appears disconnected from the underlying sediments of the DBF, Boonah Formation and UEVF by thick layers of clay located at its base. This, amongst other evidence-based observations is why in the past it's been referred to at a perched water table aquifer (PWT).

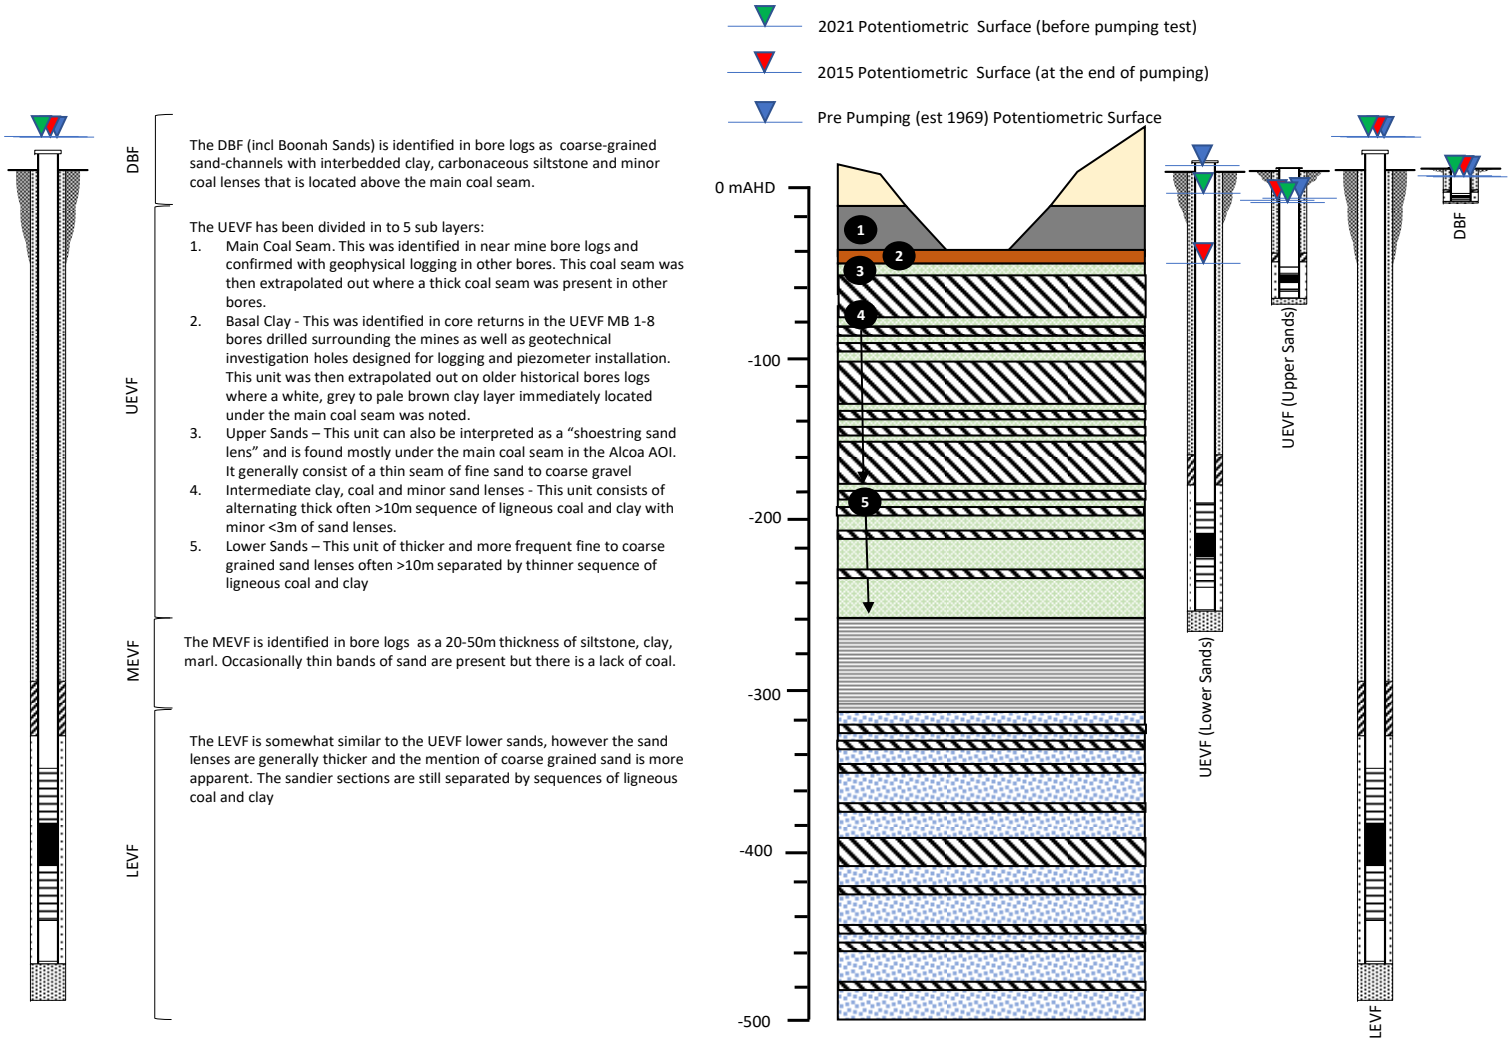

Figure 5-38 Overview of the Hydrogeological Units within the AOI

5.4.2 Demons Bluff and Boonah Formation Overview

A total of 37 groundwater observation wells have been installed across the former power station site, and 8 groundwater observation wells installed across the Alcoa Coal Mine site targeting the DBF and Boonah Formation. Due to the interconnectivity of the DBF and upper part of the Boonah Formation, it is hard to distinguishing in which many bores of these bores are screened. Where there is some uncertainty or where bore screens are likely to have screened the base of the DBF (most likely the Salt Creek Formation) and the top of the Boonah Formation, these are labelled DBF/BF.

The location of these wells and the interpreted spatial extent and current elevation (as of 17 November 2021) of the water table of this unit is shown on **Figure 5-39**.

Groundwater conditions at the Alcoa Coal Mine indicate that the DBF nearer the coal mine is largely unsaturated. For the saturated DBF bores located nearer the former power station, groundwater levels generally fall within the -4 to +4 m AHD range, which was the same range previously reported for the unconfined aquifer prior to Alcoa development (Hancock, 1967). This, combined with the absence of any widespread increases in DBF groundwater levels since Alcoa groundwater extraction from the UEVF aquifer ceased in 2016, indicates that past site activities, such as groundwater extraction from the UEVF or mine dewatering, are unlikely to have resulted in significant decreases in water levels within the DBF aquifer.

The direction of groundwater flow is expected to follow topography as well as being influenced by the mine pit void.

In addition, a discontinuous artificial perched system (PWTa) also exists within the upper weathered and disturbed zones of the DBF underneath the former power station. The PWTa is likely present due to past impacts from the former mine infrastructure such as the cooling tower, former ash ponds (now water reclamation pods) and stormwater management system.

In the majority of cases (i.e. those bores located away from the ASA or bores located adjacent to mine infrastructure influencing recharge, detailed information such as water quality and past hydraulic behaviours has been excluded from this report as much of the PowerStation have been decommissioned and the recharge controls on these systems removed. Further information regarding the behaviour of these artificial perched water tables and other shallow hydrogeological controls are found in EHS Support, 2021, Detailed Site Investigation, Alcoa Anglesea Power Station (April 2021) and EHS Support, 2021a, Supplemental Surface Water, Soil and Groundwater Investigation Works, Alcoa Anglesea Power Station(April 2021). These reports were submitted and verified by the EPA appointed Environmental Auditor, Darryl Strudwick, on 29 April 2021, to fulfil obligations of Clean Up Notice (CUN 90011694).

5.4.2.1 Water Levels and Trends

Historical annual groundwater elevation trends in the DBF aquifer are presented on **Figure 5-42**, and demonstrate relatively stable levels over time. Hourly water level data obtained during the groundwater pumping test are presented on **Figure 5-43**. The historical and current groundwater elevations are similar and show a stable trend.

The groundwater bores that display the greatest fluctuations such as MW08, MW016 and MW023 are generally located in proximity to the groundwater mounding below the former power station and cooling tower area and is directly influenced from the overlying PWT aquifer. Three locations have shown a notable decrease in groundwater levels since the power station operations ceased. The variability of water levels and presence of dry wells screened in the same unit highlights the discontinuous and complex nature of the DBF aquifer across the area.

More continuous pressure data has been recorded from four boreholes were drilled near the south wall in 1999, and piezometers were installed to monitor the water level with the DBF and Boonah Sand. These are,

- Hole 756 which targets a minor coal seam (Piezometer 1) and the Boonah Formation (Piezometer 2).
- Holes 762 which targets the DBF (Piezometer 3).
- Hole 764, which targets the DBF (Piezometer 4 and 5).
- GT2016_01S which targets the DBF.

Logs and piezometer depths are shown on **Figure 5-40.** Their historical elevation data is shown on **Figure 5-41**. This graph also shows piezometers GT2016_01D and GT2016_02D which target the UEVF upper sand/Intermediate clay.

The results show that levels remained quite consistent, with Hole 762 (P3) responding slightly to drainage of the more permeable section during the early 2000s when 10 dewatering holes were drilled at this location to dewater an observed perched water table (Mining One 2017). Hole 756 (P1) monitoring the Boonah Sands, seems to response to a wet period between 2000 and 2002.

It should be noted that the response from Hole 762 (P3 @ 15.29m RL) and Hole 764 (P4 @ 29.0m RL), the piezometer is likely reading a virtually dry hole.

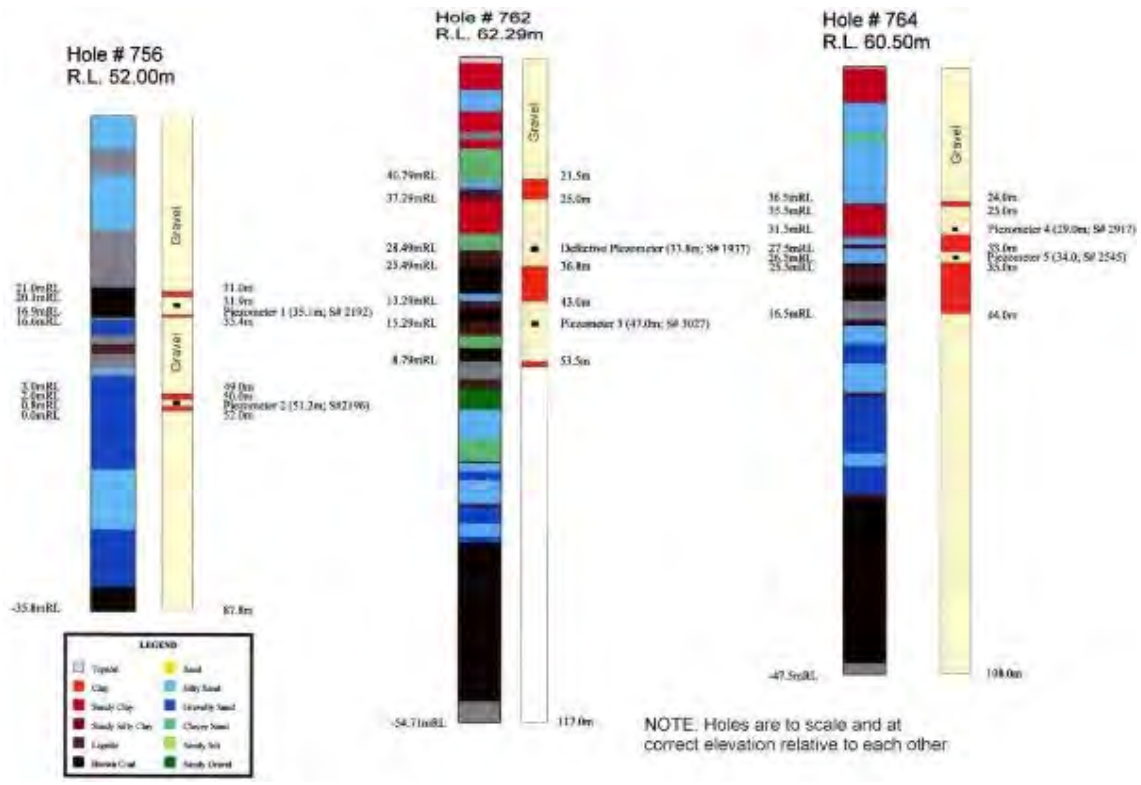

Figure 5-40 Boreholes and Piezometers in South Wall, 1999

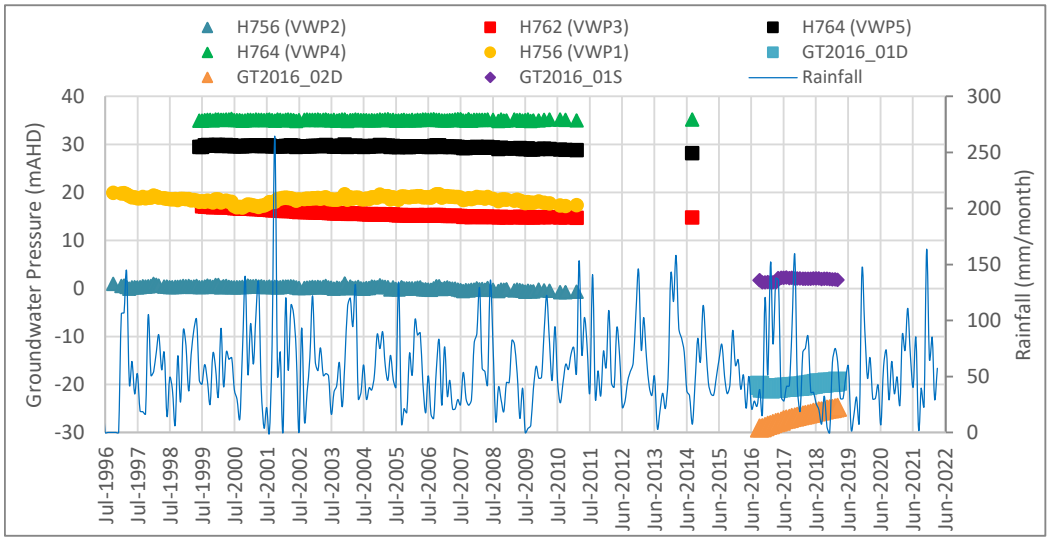

Figure 5-41 Boonah Formation and Potentiometric Surface

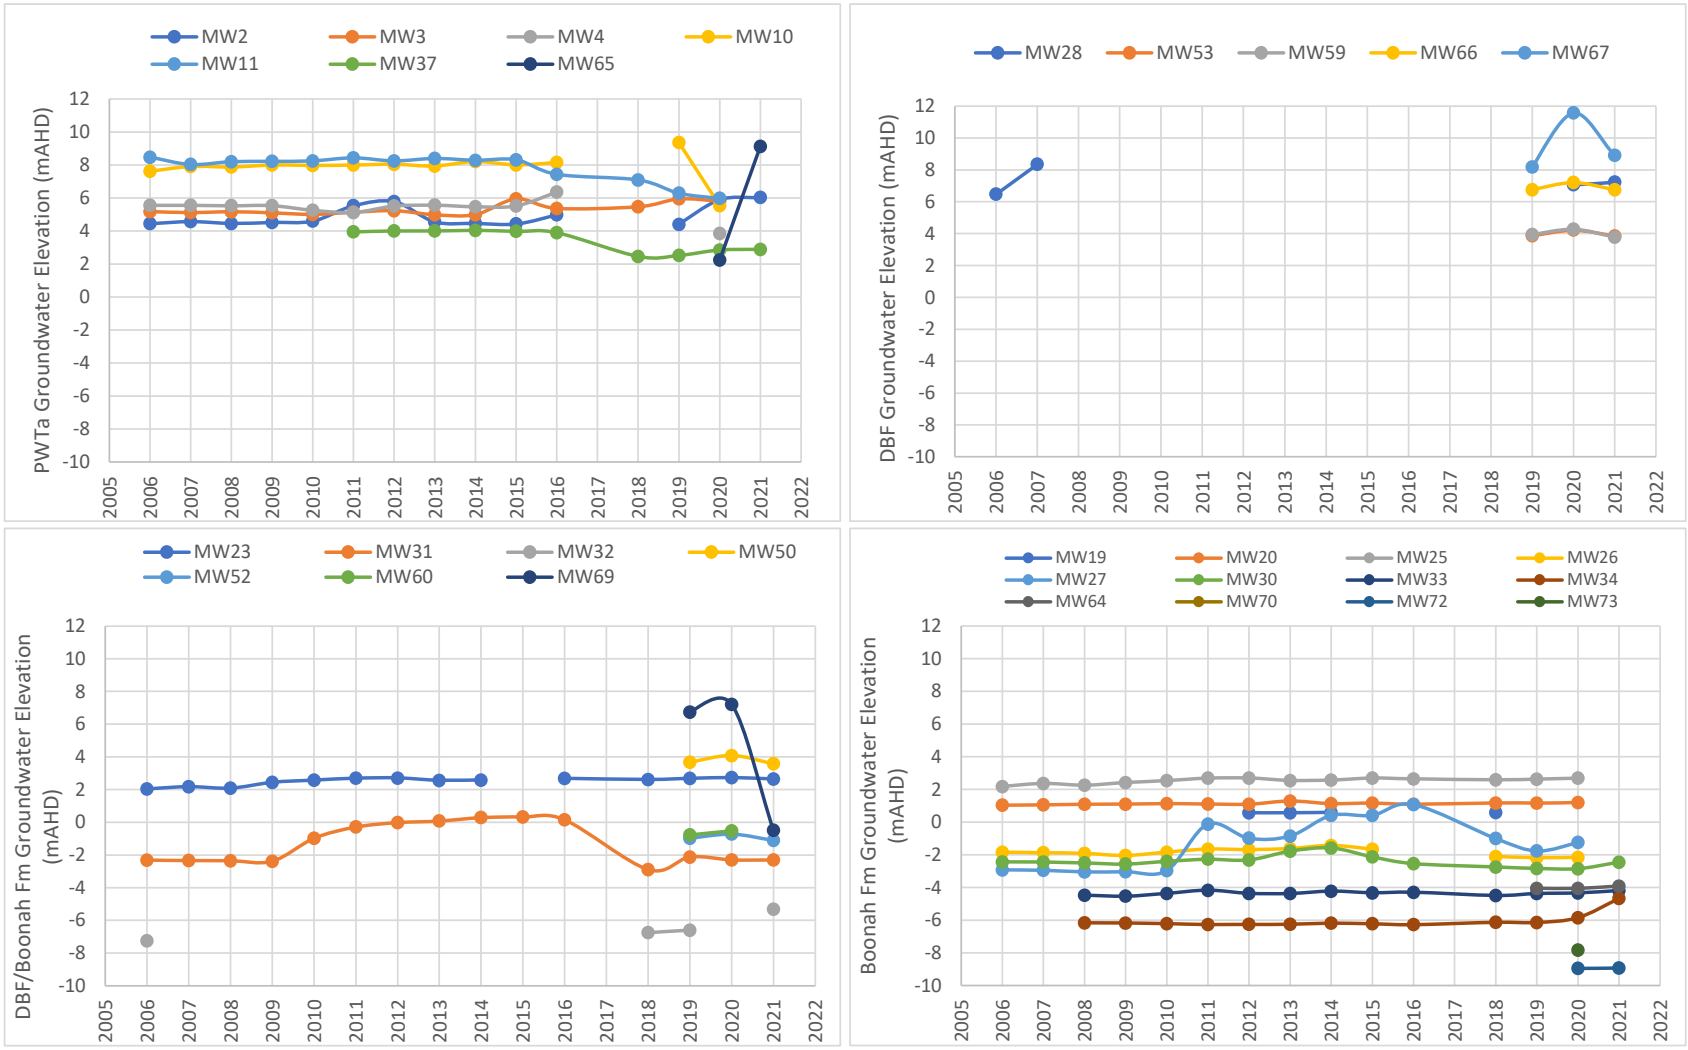

Figure 5-42 Historic Groundwater Elevations in the DBF/Boonah Fm

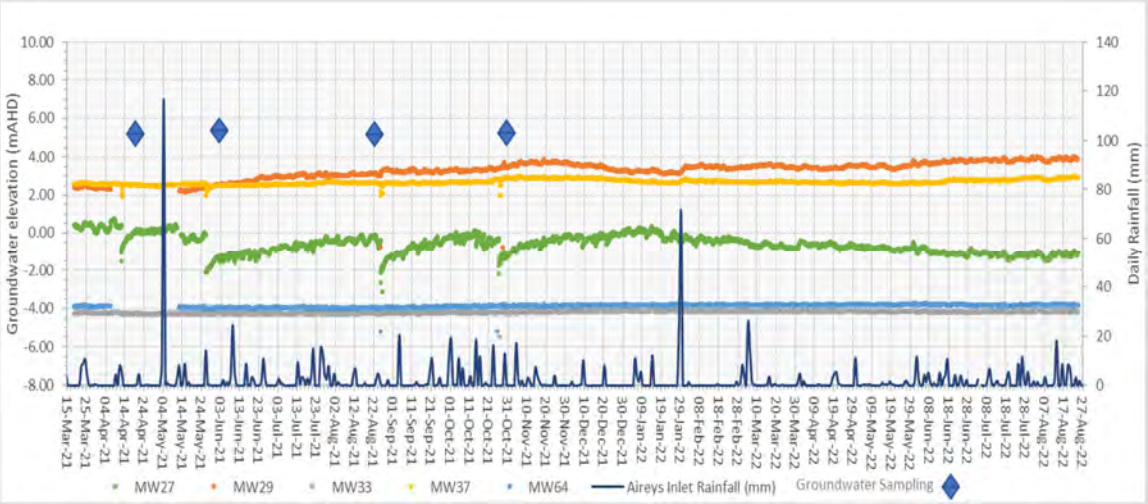

Figure 5-43 Daily DBF/Boonah Water Level Trends Recorded During the Pumping Test

5.4.2.2 Groundwater Quality

TDS in the DBF aquifer from the recent groundwater monitoring event in 2020 ranges between 578 mg/L and 6,660 mg/L with an average of 2,519 mg/L. The TDS from most wells is classified as Segment B or higher. MW29 shows the highest value and variability in TDS. This is located near the swamp at AV2 which also shows significant variability in TDS (1800 to 7020). This comparison is shown on **Figure 5-46**.

In the vicinity of the mine, the only monitoring bore that was saturated was DBF MB06 with an average TDS of 2,770 mg/L (**Figure 5-45**). This bore is installed within the backfilled overburden material and as such is not representative of the broader DBF (Boonah Formation) aquifer.

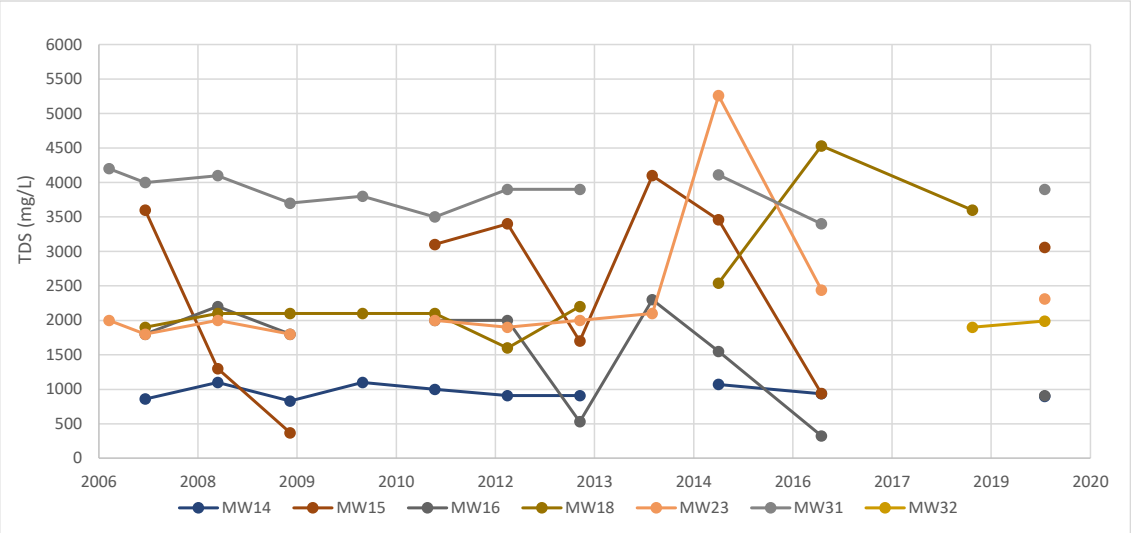

Figure 5-44 Historic TDS Concentrations in the DBF Aquifer

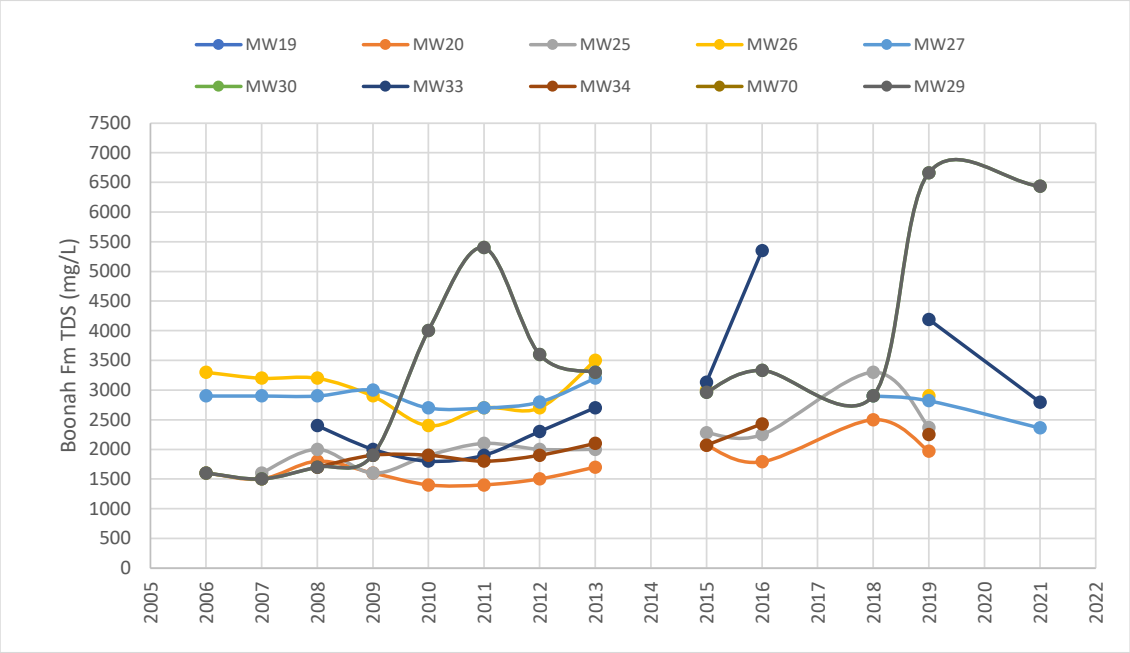

Figure 5-45 TDS Concentrations in the DBF Aquifer Recorded During the Groundwater Pumping Test

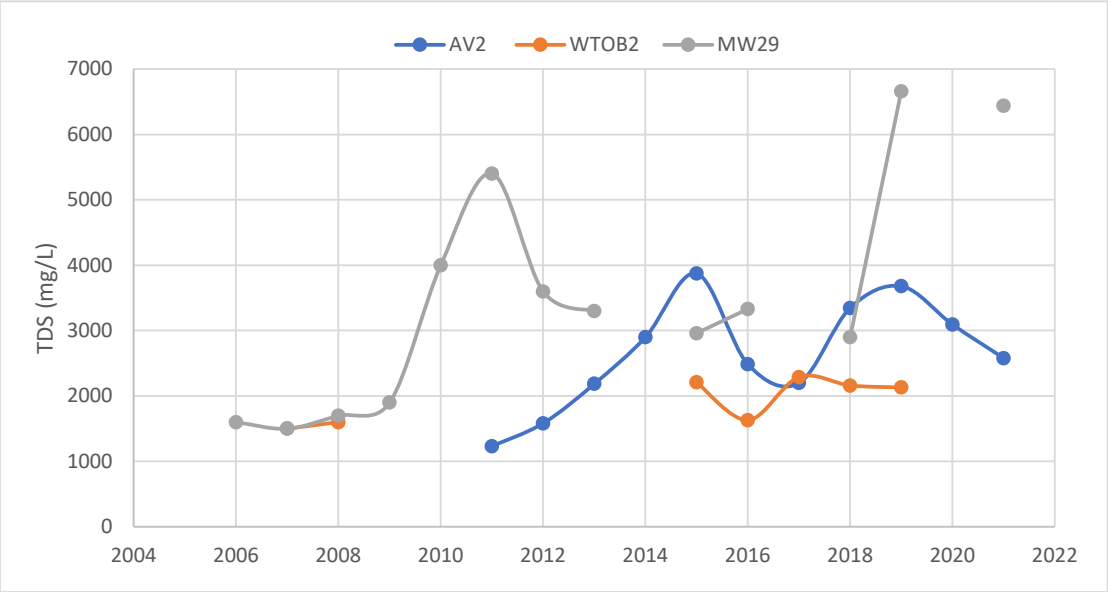

Figure 5-46 TDS Concentrations of WTOB2 (ASA), MW29 (Boonah Fm) and AV2 (surface Water)

5.4.2.3 Hydraulic Parameters

Estimates of hydraulic conductivity in the DBF (likely the Boonah Formation) were calculated from slug tests for four monitoring bores, MW4, MW10, MW11 and MW22 (Beattie, 2003). A summary of the results are presented in **Table 5-2**.

Table 5-2 Slug Test Summary (DBF)

Bore	Lithology	Bore Depth (m)	2015 Standing Water level (m AHD)	2015 EC (µS/cm)	Hydraulic Conductivity (m/day)
MW4	Silty Clay	3.5	5.7	7,170	0.09
MW10	Silty Sand	5.6	8.4	2,630	0.01
MW11	Clayey Gravel	5.5	8.3	3,260	0.27
MW22	Silty Clay	11.8	1.6	3,410	0.06

m = metres
AHD = Australian Height Datum
µS/cm = microseimens per centimetre
EC = electrical conductivity

In addition, during the 2021 drilling program, geological core was taken from the DBF (Boonah Formation) in the vicinity of UEVF MB07 (**Figure 5-39**). These core samples were analysed by Golder Associates geotechnical laboratory for permeability, dry density, porosity, reactivity and dispersion analysis. The results are presented in Table 5-3 and the laboratory reports are located in Appendix E. These tests were focussed on the clayier and compact erodible mine material of the Boonah Formation as opposed to the sandier lenses.

Furthermore, permeability tests from 29 sites located in the mine void representative of the reworked and backfilled BDG at depth between 0.5m and 8m show Kv (min = 6.9E-6m/d, max = 6.05E-3 and mean = 8.6E-5m/d). This work was undertaken after a four-day field sampling event to collect samples for permeability, chemical and Australian Standard Leaching Procedure (ASLP) analysis. The sampling event was focused on the north east part of the mine and within the fill material, which is assumed to be representative of backfilled mine overburden. These results are presented in **Table 5-4** and **Table 5-5**. The location of these sample sites is shown in **Figure 5-47** and **Figure 5-48**. Further information on these results is presented in EHS Support 2022 (Draft).

Finally, apart from where the permeable sections of the Boonah Formation may directly outcrop, groundwater and surface water interactions are expected to be limited. This is evidenced by hydrographs showing no instantaneous responses to episodic rainfall events (**Figure 5-43**). In addition, **Figure 5-49** presents pooled water photographed on 29 August 2021 on top of the DBF (Anglesea / Salt Creek Formation) near bore DBF MW07 after almost 40 mm fell in the prior 7 days. This water remained for 6 days before evaporation and infiltration eventually reduced the saturated surface area.

Figure 5-49 Recharge Potential of the Low Permeability DBF

5.4.3 Upper Eastern View Formation

Generally, the UEVF forms an unconfined (where it outcrops) to confined aquifer and consists of clay, silty clay, silt and fine to medium-grained sand sequences with minor fine gravel lenses. Brown coal is also common in the top of the UEVF sequence. In the vicinity of the Alcoa AOI, the UEVF is confined, and approximately 250 m thick. Whilst the unit has been classified as a single aquifer, evidence of different potentiometric heads exists (through site observations by Hancock [1967], as well as in recent installation of observation bores) throughout the profile.

Hancock (1967) noted artesian waters at several bores drilled in the region. Of these bores, one bore located on the Anglesea Golf Links drilled to 442 mbgl was believed to be completed in the LEVF. Another labelled “M274” located near the former power station site required an artesian cap after it flowed during drilling. This bore had flowed open hole from a sand recorded at a depth of 138 mbgl or approximately 120 m AHD, with an artesian head of 20.7 m AHD (approximately +2.7magl), a TDS of approximately 500 parts per million (ppm) and an approximate pH of 5.5. This is believed to be completed at the top of what is referred to within this report as the Lower sands; **Section 5.2.2.2.5**) and gives a good indication of the pre-mining UEVF potentiometric surface. Hancock (1967) also noted that within the EVF, ‘*sand aquifers occur in the sequence and show potentiometric pressures increasing in the deeper sand, possibly due to lithostatic pressure*’.

This is an important observation, as it gives an indication that the more permeable units in the upper part of the UEVF (i.e., just below the coal located from -65 m to -80 m AHD [approximately 55 to 70 mbgl]) are somewhat hydraulically disconnected and/or have significant response lags to induced pressure changes originating from the deeper part of the formation.

As a result, and from site investigations, the UEVF has been sub-divided into several units:

- UEVF Main Coal Basal Clay.
- UEVF Upper Sands.
- UEVF Intermediate Coal and Clay.
- UEVF Lower Sands.

Further discussion on each sub-unit of the UEVF is provided in the following sections.

5.4.3.1 Main Coal Basal Clay

A 1-4m thick clay unit underlies the mined coal seam within the Alcoa AOI and has been assessed in the following investigations:

- In 2013, a failure of the outer (southern) edge of a coal haulage ramp occurred in the north of the pit, by sliding on the south-dipping Basal Clay. Samples were collected from exposed clay and direct shear tests were conducted on remoulded samples; and
- In early 2016, Mining One conducted a field investigation of the Basal Clay, comprising three test pits and two drill holes. The work is presented in Mining One (2016) prepared a factual report of the data from tests from 2013 and 2016, the findings of which are summarised below.

5.4.3.1.1 Basal Clay Sampling

Three test pits and two drill hole locations were selected for sampling, at locations shown on **Figure 5-50**. Test pits were excavated on 24th February 2016, using one of Alcoa's 200 tonne excavators. The intention was to expose the coal/clay contact, and sample it either with 150 mm push tubes, or the trim around it and remove a 300 mm undisturbed cube. The sampling method was to be selected when the coal/clay contact was exposed and inspected.

- At Pit 1, the excavator found it difficult to break up the approximately 1m depth of coal remaining on the floor of the mine. The exposed clay contact was very stiff. The pit encountered no groundwater. A bulk sample was retrieved and is shown in **Figure 5-51**. Due to the coal being very hard and brittle, it was virtually impossible to sample the coal/clay interface in an undisturbed state.
- At Pit 2, the contact was wet, possibly because the location was in a depression in the coal floor. The Basal Clay was very stiff, as it was in Pit 1, but the contact between the coal and the clay was a zone of crushed coal and weak clay that appears to have been sheared or disturbed. An in-situ view of the contact is shown in **Figure 5-52**, and a sample recovered with considerable difficulty is shown in **Figure 5-53**.
- At Pit 3, the coal was again too hard, brittle, and jointed to be able to cut an undisturbed sample. The pit was extended to a long trench to get a better visual assessment of the contact. The contact is shown in **Figure 5-54**. .

Two sites were selected for boreholes. The intention was, at each site, to drill an exploratory hole using an auger to locate the base of the coal, then to drill one or more (as required) diamond cored boreholes using a PQ size core barrel (85 mm core size), taking care to core the coal/clay contact at the known depth. The diamond holes were cased through the overburden that covers the coal, then were diamond drilled for the last 0.5 m of coal and about 1 m into the Basal Clay. Each hole was about one metre from its neighbour.

- At Drill Site 1, despite several attempts at a number of locations at the site, there was either no or minimal clay recovered by the core barrel. No reason for this lack of recovery could be determined. Attempts were made to drill very slowly through the hard coal to the soft

contact and also the reverse by drilling fast through the clay to avoid washing it away. No clay was recovered at the contact in most cases.
A short sample of the clay was recovered in the core lifter. However, this had to be disturbed to recover it. This sample is shown in **Figure 5-55**.
Further inspection of the recovered coal and underlying disturbed clay suggested that there may be a carbonaceous shale or lignite at the base of coal, where shearing/disturbance has occurred. This is shown in **Figure 5-56**.
An attempt to recover a sample using the Geoprobe tubes was unsuccessful as the probe barrel could not be driven through the hard brittle coal. The probe uses a top hammer with around 2,000 impacts per minute to force the probe barrel down through typically soft formations such as sands and clays.

- At Drill Site 2, the PQ core barrel did not recover any substantial clay fraction. The only sample recovered was a minimal segment of coal with a thin layer of clay / lignite. This sample correlated to the auger probe hole, where a dry layer of silty clay was recovered. It could not be determined whether the lignite / clay was being washed away or being pushed aside as it was too soft / friable to push the coal further up the core barrel.

In addition to the information presented above, within core hole UEVF MB07, the shallowest clay underlying the main coal (inferred as the continuation of the basal clay) returned a permeability (vertical hydraulic conductivity) of 7×10^{-10} m/sec (6×10^{-5} m/day). Laboratory reports are provided in **Appendix H**.

The spatial extent of the Main Coal (seam A) and basal clay are shown on **Figure 5-57**. Note this differs from the larger extent presented on **Figure 5-34** which incorporates all the upper coal seam in the area.

5.4.3.2 UEVF Upper Sands

Within the Alcoa AOI an upper permeable sand unit within the UEVF was observed in numerous observation and investigation bores across the Alcoa Coal Mine. Where these sands were encountered underneath the main mined coal seam, groundwater observation bores were installed. Where no sand lens was encountered immediately below the main coal seam, the next sand lens was targeted. Seven groundwater observation bores were installed in this unit in 2020/2021 and are shown on **Figure 2-2**.

The upper sands of the UEVF forms a discontinuous permeable unit that is separated from the shallow DBF by the basal clay and main coal seams. The spatial extent and current groundwater elevation (as of January 2022) of the water table of this unit is shown on **Figure 5-59**.

5.4.3.2.1 Water Levels and Trends

Seven groundwater monitoring bores were installed within the UEVF Upper Sands, and their hydrographic response is shown in **Figure 5-58**. In all bores the groundwater elevation is rising at a similar rate of approximately 0.2 m/month and has not been impacted by the groundwater pumping test.

5.4.3.2.2 Groundwater Quality

The TDS within the upper sands is variable ranging from 168 mg/L (UEVF MW07) to 3,470 mg/L (UEVF MW04) with a median concentration of 889 mg/L. The trend in TDS at each location has remained relatively stable over time (**Figure 5-60**).

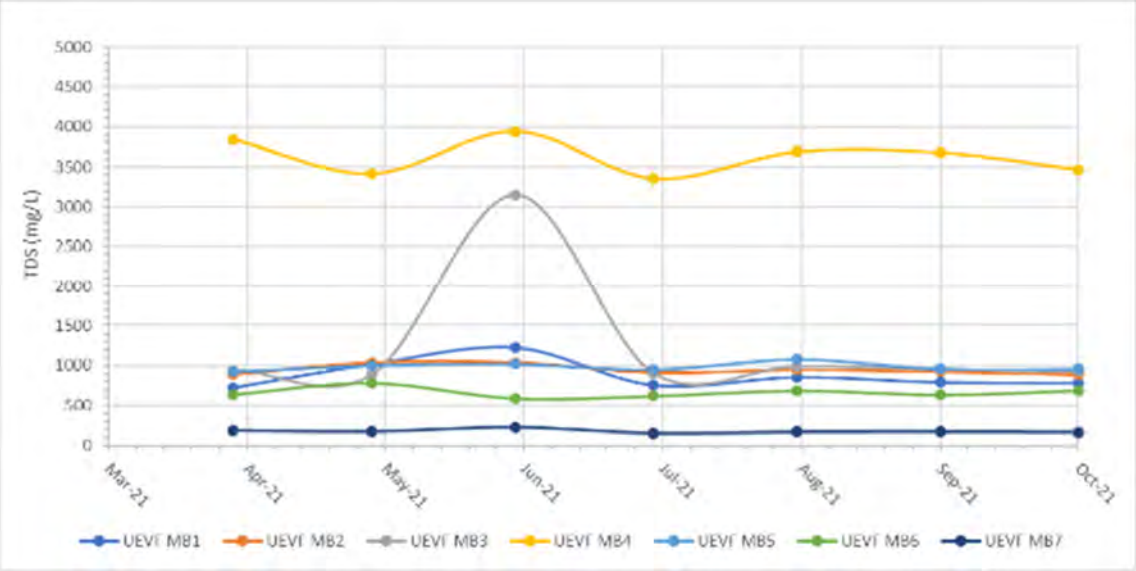

Figure 5-60 UEVF Upper Sands TDS Concentrations

5.4.3.2.3 Hydrogeological Parameters

No aquifer tests have been undertaken on the upper sands, however based on observed core sands returns from UEVF MB07 (**Figure 5-31**) and other bores, the hydraulic conductivity would be high (potentially up to 20 m/day) although these permeable sand lenes are only thin (and potentially discontinuous), which would result in a reduced transmissivity across the area.

5.4.3.3 UEVF Intermediate Coal and Clay

The intermediate clay, coal and minor sand lenses of the UEVF consists of alternating thick often greater than 10 m sequences of ligneous coal and clay with minor less than 3 m of sand lenses. Underneath the former mine, the total combined thickness of this unit is approximately 100 m. The outcropping extent of this section of the UEVF is estimated on **Figure 5-6**.

5.4.3.3.1 Water Levels, Groundwater Quality and Trends

As the name of this section of the UEVF suggests, there are limited permeable units and as such no water level or water quality data exists for this section of the overall formation.

5.4.3.3.2 Hydrogeological Parameters

During the installation of groundwater investigation bores surrounding the mine void, geological core was retained from several bores (UEVF MB7, UEVF MB3 and UEVF MB8) and 5 core sections within UEVF MB7 were subject to laboratory permeability tests. These sections were all from the coal and clay seams within the UEVF Intermediate zone which represent the lower permeability sections of the formation. The laboratory permeability tests of clay and coal sections indicate that vertical hydraulic conductivity (Kv) ranges from 7 x 10^{-10} m/sec at 33 mbgl to 3 x 10^{-9} m/sec at 55mbgl to 2 x 10^{-9} m/sec at 70.5 mbgl and 1 x 10^{-10} m/sec at 140 mbgl. The certificates of these results are presented in **Appendix H**.

5.4.3.4 UEVF Lower Sands

At the site, the UEVF Lower sands are confined by greater than 100 m of coal and clay that separate these sands from shallower permeable units (refer to sections above for lithological relationship between these two units). These clays and coals are indicated to act as a quasi-confining unit. The outcrop areas of the UEVF Lower sands are estimated on **Figure 5-6**.

A number of dewatering bores were installed by Alcoa across the former power station site targeting the lower sands of the UEVF to facilitate mining operations. Four of these dewatering bores are currently being monitored and are shown on **Figure 5-61**. The remainder of these dewatering bores have been decommissioned for various reasons.

Static groundwater elevations from May 2021 (i.e., prior to the commencement of the 12-month pumping test) indicate greater hydraulic pressures in the lower sands of the UEVF compared to overlying units (i.e., those in the upper sands).

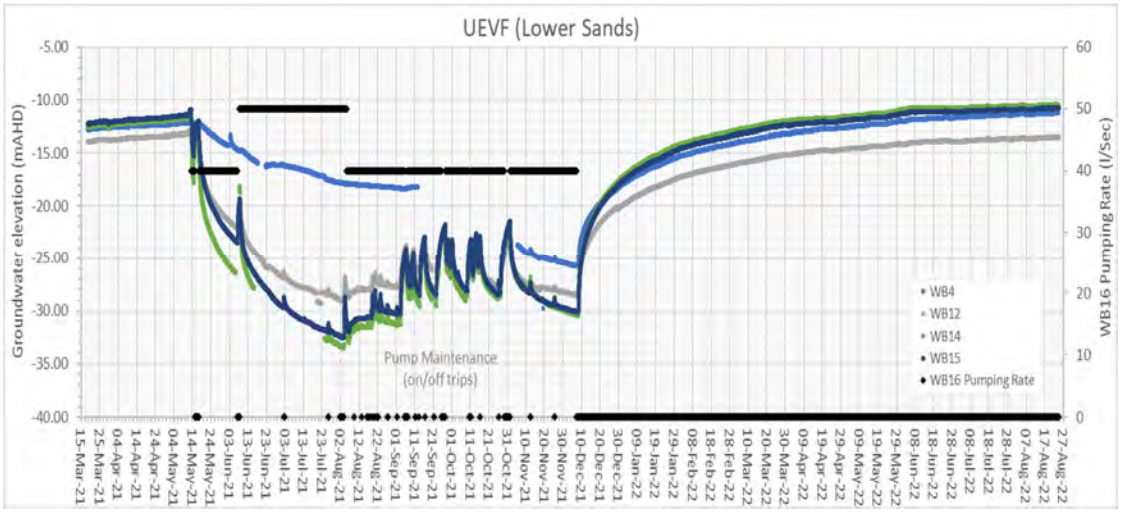

Figure 5-61 Daily UEVF Lower Sands Water Level Trends during the Groundwater Pumping Test

5.4.3.4.1 Water Levels and Trends

Figure 5-62 presents historic bore water level data in the UEVF with WB4, and WB5 being screened in the deeper portions of the UEVF. These bores are screened closer to (both spatially and vertically) the pumping bores and as such have been impacted by Alcoa's UEVF pumping. However, since pumping has ceased in 2016, groundwater is recovering at a faster rate than those screened in the

upper section, highlighting the disconnect between the upper and lower sections. **Figure 5-63** presents the groundwater contours of the UEVF Lower Sands at the end of 2021.

5.4.3.4.2 Groundwater Quality

During the groundwater pumping test pH ranged from 6.3 to 6.7 with a mean of 6.5. The TDS ranged from 741 to 1,660 mg/L which is consistent with historical ranges reported prior to May 2021, of between 830 to 1,313 mg/L, indicating negligible changes in water quality due to the groundwater pumping test (**Figure 5-64**). Recorded trace metals concentrations (i.e., aluminium, boron, iron and zinc) during the groundwater pumping test are also consistent with historical observations (**Table 4-5**).

Figure 5-64 UEVF Lower Sands TDS Concentrations Recorded During the Groundwater Pumping Test

5.4.3.4.3 Hydrogeological Parameters

In 2015 and 2016, groundwater monitoring data associated with extraction activities from extraction bores WB3 and WB4 (screened in multiple locations across the UEVF) for the period November 2015 to June 2016 were analysed (**Table 5-6**). During the 8-month monitoring period, extraction bore WB3 was active over 4 pumping cycles ranging from 1 day to 10 days at pumping rates of up to 49 L/sec. Extraction bore WB4 was active over 9 cycles ranging from 2 days to 18 days pumping at rates of up to 44 L/sec. During these pumping cycles, groundwater levels were collected from observation bores WB1, OB4, OB5, OB9 and OB12. Vibrating Wire Piezometers (VWP1D and VWP2D) were also active during the later pumping cycles and were screened in the upper sections of the UEVF whilst the remaining bores (with the exception of OB4), were screened in the lower sections of the UEVF. OB4 was screened across both the UEVF and LEVF.

Data obtained from numerous hydraulic response periods was analysed in Aqtesolv™ (HydroSOLVE, Inc.) using the Cooper-Jacob solution with unconfined correction (1946). A summary of the derived hydraulic parameters are provided in **Table 5-6**.

Table 5-6 2015/2016 Pumping Periods Analysed

Test	Pumping Bore	Test Type	Observation Bore	Cooper-Jacob (Unconfined)

			WB9	483	6.9×10^{-4}
			WB12	194.8	7.4×10^{-4}
Test Duration 10 (84.5 to 92.5 days)	WB4	Recovery	WB4	572.5	5.4×10^{-3}
			WB5	282.8	2.4×10^{-3}
			WB9	382.6	5.5×10^{-4}
			WB12	161.8	6.5×10^{-4}
Test Duration 11 (96.5 to 107.5 days)	WB4	Pumping	WB4	No Response	
			WB5	385.7	3.0×10^{-3}
			WB9	382.6	6.0×10^{-5}
			WB12	161.8	6.4×10^{-4}
Test Duration 12 (115.5 to 116.5 days)	WB4	Pumping	WB4	83.2	2.0×10^{-5}
			WB5	29.03	4.0×10^{-5}
			WB9	64.03	1.0×10^{-5}
			WB12	9.83	2.0×10^{-5}

The results from WB5, WB9 and WB12 contained uniformity (i.e., each well had a normal distribution of its group of transmissivities) despite the variable stress periods and stress rates. For example, the transmissivity values for WB4 were almost double that of the other bores. To further analyse this, the mean and the standard deviation for each bore were determined (**Table 5-7**)

Table 5-7 Statistical Summary of Observation Bores

Bore ID	Mean of Transmissivity	Standard Deviation of Transmissivity
WB4	809.5	494.9
WB5	309.3	123.8
WB9	444.7	199.2
WB12	213.2	133.8

The aquifer parameter data suggest hydraulic conductivities of up to approximately 10 m/day can occur in individual sand horizons within the UEVF. However, lower average (or bulk) hydraulic conductivities of between 0.001 and 1 m/day have been recorded where longer and more varied sequences of sand, silts and clays have been tested.

Between 21 April 2020 and 29 April 2020, EHS Support undertook a step drawdown test consisting of three steps, and a seven-day constant rate pumping test from production bore WB16. The objective of the pumping test was to obtain an estimate of the aquifer properties (i.e., transmissivity and storativity) of the lower sands of the UEVF in the vicinity of the pumping bore location. The derived parameters were incorporated into the original numerical groundwater flow model.

During the step-drawdown test, the drawdown at the pumping bore (WB16) varied from approximately 21 m at 30 L/sec to approximately 40 m at the end of Step 3 at 50 L/sec. The specific capacity was approximately 1.3 L/sec per metre of drawdown. A well efficiency of approximately 80 percent was indicated for the pumping ranges used; however, at higher pumping rates, the well efficiency declined because of the increasing significance of well loss. Transmissivity was derived using Aqtesolv™ and the Dougherty-Babu (1984) solution was adopted. The displacement data did not indicate boundary condition effects, such as a recharge boundary or barrier boundary (i.e., geological dyke). The analysis indicated a transmissivity of 122.8 m^2/day.

The seven-day constant rate pumping test was conducted from 22 April 2020 to 29 April 2020 at WB16 to evaluate aquifer hydraulic properties when a steady stress was placed on the aquifer. Based on a review of available information and the results of the step-drawdown pumping test, a preliminary pumping rate estimate of 45 L/sec was made. Water level response at WB16 during the seven-day constant rate pump test indicated groundwater drawdown of 48.2 m was achieved at the pumping bore. Following pump shutdown, groundwater levels in WB16 initially recovered rapidly. Recovery was within about 94 percent of initial groundwater levels after seven days (i.e., with 2.8 m of static levels).

The time-drawdown relationship for WB16 was plotted using a log-linear (i.e., semi-log) plot to assess the indicative aquifer conditions. The plot was found to be uncharacteristic of the typical textbook relationship for confined, unconfined and leaky unconsolidated aquifers. This led to a high-level investigation of potential boundary impacts where it was discovered active extraction from the LEVF from a nearby bore (GW4) was likely impacting water levels in the UEVF.

However, and despite the potential interference, the early time data approximately resembled a confined aquifer type, and this was consistent with expectations based on geology. The Papadopolus-Cooper (1967) solution was adopted for analysis to determine the transmissivity and storativity of the UEVF. Based on the analyses of the seven-day constant rate pumping test, the estimated transmissivity was 112.9 m^2/day (hydraulic conductivity of 0.53 m/day) and a storativity of 6 x 10^{-4}. These derived parameters are consistent with previous estimates (GHD, 2013; median K = 0.65 m/day; EHS Support, 2018; median K = 0.48 m/day).

Based on the 6-month pumping test (**Appendix D**), the estimated transmissivity ranged from 58.2 to 114.2 m^2/day (hydraulic conductivity range of 0.8 to 1.6 m/day) and a storativity range of 2 x 10^{-4} to 5 x 10^{-4} (-).

5.4.4 Middle Eastern View Formation

The MEVF is approximately 40 to 60 m thick and generally behaves as an aquitard by restricting vertical groundwater flow between the UEVF and LEVF. The MEVF generally consists of mudstone and siltstone, but also has minor sand and gravel lenses as well as thin brown coal layers. The unit generally appears to be continuous and consistent in thickness throughout the Anglesea area. Geologically, this unit represents the Pember Mudstone member of the Dilwyn Formation.

The MEVF has been previously modelled as a leaky aquitard as depressurisation impacts have been observed in some deep Alcoa UEVF observation bores whilst pumping has been occurring from nearby the LEVF extraction bores. However, a recent bore assessment program involving down hole camera and wireline logging was undertaken by Alcoa to identify bores with potential integrity issues or those that may cross screen aquifers. In 2021, several at-risk bores were identified and decommissioned. Since the restarting of the LEVF extraction iby Barwon Water n early 2022, no depressurisation impacts have been recorded in the Alcoa UEVF deep observation bores. This indicates that the aquitard may not be as leaky an initially thought with these previous bores acting as preferential flow conduits.

5.4.5 Lower Eastern View Formation

The LEVF forms a confined to semi-confined aquifer (in the upper parts of the catchment) across the region and consists of unconsolidated micaceous silts, carbonaceous clays, silty clays, thin brown coal seams and fine to coarse-grained sands and gravels. At the coal mine site, the LEVF is up 200 m thick where aquifer material occurs within geological synclines. Geologically, this unit represents the Pebble Point Formation and, prior to Barwon Water groundwater extraction in the area, was artesian at the site.

5.4.5.1 Water Levels and Trends

Figure 5-65 displays historical groundwater elevations within the Barown Water pumping bores screened with the LEVF. Groundwater extraction by Alcoa from the lower sands of the UEVF has not influenced groundwater pressures within the deeper LEVF. **Figure 5-66** shows the 2021 LEVF Groundwater Elevations.

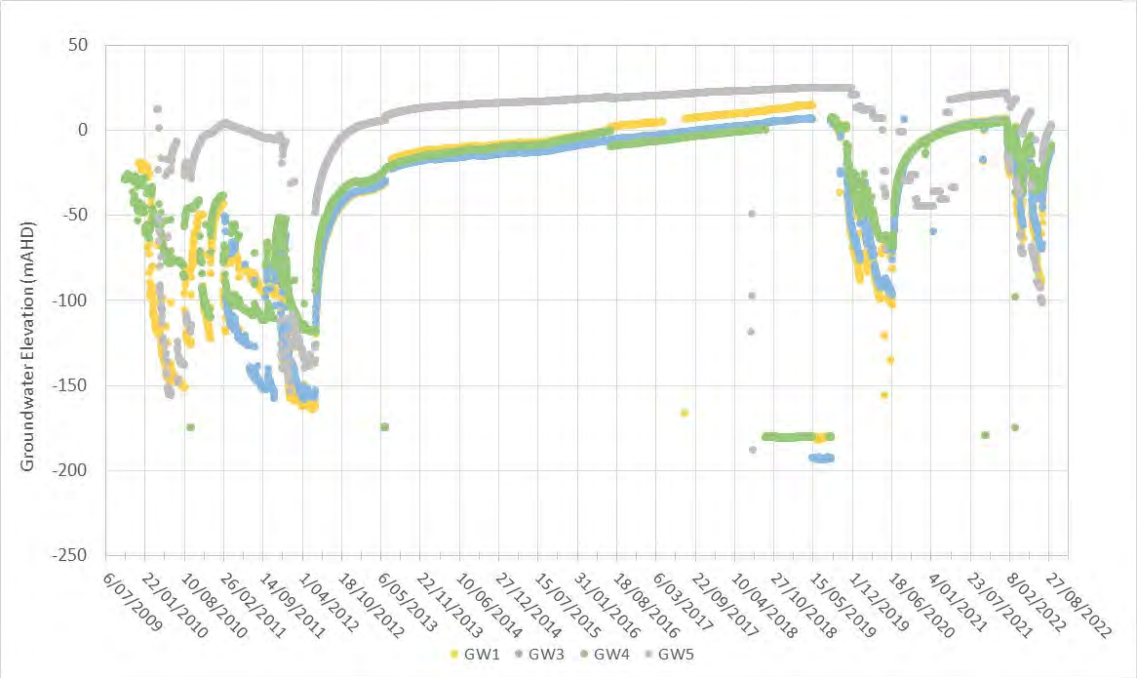

Figure 5-65 LEVF Historic Groundwater Elevations (data provided by Barwon Water)

5.4.5.2 Groundwater Quality

Groundwater quality (TDS) in the LEVF is fresher than that observed in the UEVF. GHD (2013) reported that groundwater salinity had been measured between approximately 500 to 900mg/L TDS.

5.4.5.3 Hydrogeological Parameters

A number of aquifer hydraulic tests of the LEVF have been undertaken in the region. Aquifer hydraulic parameters obtained from GW1-GW7 screened in the LEVF, have been estimated from a calibrated numerical groundwater flow model and groundwater pumping tests associated with Barwon Water's Southern Anglesea Borefield extraction program, (refer to GHD (2013) for more information).

These parameters of the LEVF, along with modelled parameters of the hydrogeological formations overlying, are presented in **Table 5-8** to **Table 5-11**. The aquifer parameter data suggest transmissivities of up to 330 m^2/day and hydraulic conductivities of up to 2.77 m/day can occur in individual sand horizons within the LEVF.

Table 5-8 Barwon Water Borefield Pumping Test Summary (after GHD, 2013)

Bore	Date	Duration (days)	Aquifer	Bore depth	Transmissivity (m^2/day)	Storativity

5.4.6 Recharge to the EVF

Groundwater recharge to the EVF can occur via three main mechanisms:

1. Direct rainfall across the outcrop area in the Otway Ranges
2. Leakage from the DBF and/or from river recharge
3. Upwards leakage from underlying aquifers

Through numerical modelling, GHD (2013) estimated recharge to be approximately 10 mm/year and up to 50 mm/year to the UEVF. This was also in line with estimates derived from analysing hydrograph fluctuations within the UEVF where the recharge was estimated to be to be approximately 2 to 7 percent of the average annual rainfall over the outcrop area (approximately total annual rainfall of 700 to 900 mm/year)[9].

Direct recharge into the DBF is expected to be lower due to its outcrop area occurring in regions of lower rainfall and an increase in clay through its lithology.

5.5 Surface Water/Groundwater Interactions

The potential for surface water and groundwater interactions is described in the following segments:

- Upper reaches of the Anglesea River (also referred to as Marshy Creek).
- Swamps associated with the mid-reaches of Anglesea River/Marshy Creek.
- Lower Anglesea River.
- Upper Salt Creek.
- Lower Salt Creek.
- Former Power Station and mine void footprint.

Refer to **Figure 4-2** for the location of each segment above. Where the surface water segment is located outside of the Alcoa AOI (e.g. Upper Salt Creek and the upper reaches of the Anglesea River) the most up to date information has been summarised and referenced. To assist in ensuring those conclusions from these key references are still valid, recent groundwater observation data supplied from Barwon Water have been used in updated conceptual cross sections.

5.5.1 Upper Anglesea River

The previously documented (Hermon, 2002, Maher, 2011, GHD, 2013 and 2017) key surface water/groundwater interactions that occur are summarised below:

- The Upper Anglesea River is ephemeral and the UEVF aquifer is generally absent in this area.
- The salinity of the ASA generally ranges between 1,000 and 1,600 mg/L and is higher than the salinity of the LEVF (600 to 800 mg/L) as evapotranspiration helps concentrates salts within the ASA.

[9] the estimated recharge above is significantly lower than the 27 percent of rainfall used in the current determination of the Jan Juc PAV of 11,250 ML/year (comprising 250 ML/year from all formations in Zone 1; 4000 ML/y from the UEVF in Zone 2; and 7000 ML/year from the LEVF in Zone 2).

- The recorded groundwater level in the LEVF aquifer is around 7 m below the base of the river bed, and the groundwater level in the ASA is below the river water level, confirming that the river system is a potential losing system and not baseflow dependent.
- The head differences and the different temporal patterns observed between the ASA and the underlying LEVF aquifer suggests the ASA acts as a PWT with limited, or no connectivity to the LEVF.

In addition to the above, recent long term water level data presented in **Figure 5-70**, supports the previous conceptual understanding. The lines of evidence for this are:

- With the exception of an episodic rainfall event of 60mm on 14/11/2015, all other large rainfall events exceeding 40mm have resulted in an increase of P18 (ASA) groundwater levels to within centimetres of its maximum levels. Only a small "diffuse" response to rainfall is observed in P3 (LEVF) indicating limited connectivity between the LEVF aquifer system and the ASA in this location.
- Stage water level height variations at gauging station AV1 correlate well with the groundwater level fluctuation in the ASA indicating rainfall recharge is the dominant driver of recharge to the ASA.
- Between November 2014 and May 2016, the region experienced low rainfall. This caused a continual drop in groundwater levels within the ASA. The largest rate of decline was during spring and summer of 2015 and 2016. As the underling LEVF aquifer exhibits no trend either during or in the several years pre and post this period and as evaporation and evapotransipration are highest during spring and summer, this suggests that evapotranspiration is the most likely cause of water loss from the ASA as opposed to diffuse leakage to the underlying ASA.
- Assuming some diffuse leakage from the ASA to the LEVF occurs with hydraulic properties as detailed in **Table 5-10** and **Table 5-11**, Darcy flux (q = k(dH/dL) suggests this to be $2x10^{-5}$ m/d. Assuming the porosity of the underlying formation is 0.13, it would take ~142 years for the groundwater leaking from the ASA to reach the LEVF at P3.

5.5.2 Swamps Associated with the Mid-Reaches of Anglesea River/Marshy Creek

The previously documented (Hermon, 2002, Maher, 2011, GHD, 2013 and 2017) key surface water/groundwater interactions that occur are as follows:

- The salinity of the ASA generally ranges between 1,300 and 1,600 mg/L. The salinity of the UEVF generally ranges between 640 and 820 mg/L and the salinity of the LEVF ranges between 640 and 790 mg/L).
- The LEVF aquifer is artesian in this area. The high artesian LEVF heads (initially 13 m above ground level) may indicate that the river system has the potential to be a gaining system where direct connection is made.
- The UEVF and groundwater levels higher than those recorded in the ASA indicating an upward gradient exists and the shallower formations have the potential to be a gaining system.
- Several permanent water pools have been mapped (AGP1-B, AGP2 and ASP7). The LEVF directly underlies AGP1-B whilst the UEVF directly underlies AGP2 and ASP7. Groundwater chemistry including stable and radioactive isotopes indicate that these pools are not in direct connection with the underlying LEVF or UEVF aquifer and therefore not baseflow dependant despite an upward gradient existing.

- Where the MEVF aquitard is located at the base of the ASA, the low permeability of this formation effectively limits the connectivity between the LEVF and any surface water systems. During a six-month pumping test conducted by Barwon Water on the LEVF, there was no obvious decline in the ASA or UEVF aquifer heads that could be directly related to pumping and thus by inference reductions in stream baseflow. GHD (2013) noted that long-term continuous extraction (e.g., 47 years continuous high-rate extraction for the LEVF may then result in some drawdown being observed in the overlying formations).
- The ASA bores in the swamplands respond closely with rainfall events, as the aquifer system is recharged by direct rainfall and rainfall runoff.

In addition to the above, recent long term water level data presented in **Figure 5-71**, supports the previous conceptual understanding. The lines of evidence for this are:

- An upward gradient from the underling aquifers (LEVF and UEVF) to the ASA exists with the exception between 2009 and 2012 when Barwon Water conducted a series of pumping tests in the LEVF. During this period the LEVF potentiometric was lower than the UEVF or ASA. However, no impact on these shallower groundwater pressures were observed.
- Both the shallow aquifers (ASA and UEVF) have shown a stable trend over the last 10 years with no impact seen in either system despite Alcoa extraction up to 2016 and more recent aquifer tests (both in pumping and recovery stage), and also aquifer tests undertaken by Barwon Water between 2009 and 2012.
- Most large rainfall events exceeding 40mm have resulted in an immediate increase in groundwater levels within P8 (ASA) and to a lesser extent P19 (UEVF). This indicates that direct rainfall recharge is the dominant driver of recharge to the ASA and diffuse recharge at the UEVF outcrop areas may be significant in the UEVF at this location. It is at this location where the basal (and more permeable parts of the UEVF) would come close to surface.
- The steepest decline of groundwater levels occur within the ASA over spring and summer when episodic rainfall events are absent (refer spring and summer of 2012/13; 2013/14; 2015/16; and 2018/2019). This similar correlation does not hold true for the UEVF (P19). As discussed above evapotransipration is highest during spring and summer, suggesting that evapotranspiration and throughflow is the most likely cause of water loss from the ASA in this location.
- Assuming some diffuse baseflow from the UEVF to the ASA, with hydraulic properties as detailed in **Table 5-10** and **Table 5-11**, Darcy flux (q = k(dH/dL) suggests this rate to be 1.6 $x10^{-5}$ m/d. Assuming the porosity of the underlying formation is 0.18, it would take ~123 years for water to move from the UEVF and discharge in the ASA at P8.

5.5.3 Lower Anglesea River

Previously documented (Hermon, 2002, Maher, 2011, GHD, 2013 and 2017) key surface water/groundwater interactions that occur are as follows:

- Directly underlying the Lower Anglesea River is the low permeability DBF and/or the Boonah Formation.
- Salinities in the ASA were generally higher and more variable than in the upper catchment ranging between 1600 and 2470 mg/L. This has been attributed to longer groundwater travel and longer interactions with the sediments of the ASA as well as evapotranspiration concentrating the salts between flow events.

- Any surface water and groundwater interconnection between the Lower Anglesea River and underlying DBF aquifer is expected to be minimal due to the confining low permeability clays between the base of the surface water system and the aquifer.
- Locally around the mine, the groundwater pressure of the basal sands of the UEVF aquifer has been drawn down due to pumping from the coal mine.

In addition to the above, recent long term water level data presented in **Figure 5-72** (and **Figure 5-67**), supports the previous conceptual understanding. The lines of evidence for this are:

- Within the vicinity of AV2, a downward gradient exists from the ASA to the underlying aquifers. However, groundwater monitoring data from bores screened in the DBF and BF (near the former Power Station) as well as historical VWP suggest that the water table can be higher especially around areas of topographic highs.
- The UEVF Lower aquifer has been drawn down due to the historical pumping from the coal mine and bores, and there is also a downward hydraulic gradient from the ASA to the UEVF. The head difference between WTOB2 (ASA) and WB4 (UEVF) was approximately 20m as shown in **Figure 5-67**. Therefore, as shown by the relative groundwater levels, the ASA aquifer, which supports the swamplands, is generally hydraulically disconnected from the underlying UEVF lower sands aquifer in the lower reaches. The downward gradient suggests the potential for some diffuse leakage from the ASA towards underlying aquifers over time, however the low permeability coals and clays in the Anglesea Syncline provide an aquitard separating the UEVF sands from the ASA in the lower reaches. There is also a degree of hydraulic separation between the ASA and the underlying Boonah Formation aquifer (which is saturated on the eastern side of the mine void) due to the DBF aquitard.
- The salinity of the underlying Boonah Formation at MW29 ranges between 1500 and 6,660 mg/L which is significantly higher than the ASA (1600 and 2470 mg/L) and underling UEVF (170 to 200 mg/L at UEVF MB7 (upper sands) and 1100 to 1500 mg/L at WB16 (lower sands). The lower salinity in the upper sands likely reflects the short travel time from its recharge point. The higher salinity in MW29 is likely representative of the high portion of clay and silt in his formation.
- Most large rainfall events exceeding 40mm have resulted in an immediate increase in groundwater levels within WTOB2 (ASA), however unlike other up gradient ASA monitoring points, these increases are smaller in size. For example, on March 13, 2017, 101 mm fell at Aireys Inlet. The corresponding rate of groundwater rise in the ASA was 1.3m at P18 (Upper Anglesea River; 0.7m at P8 and 0.5m at WTOB2).
- The underlying DBF/BF shows a diffuse recharge response to rainfall and the upper sands of the UEVF show no recharge pulse from any rainfall events.
- As has previously been observed, the steepest decline of groundwater levels occurs within the ASA over spring and summer when episodic rainfall events are absent (refer spring and summer of 2012/13; 2013/14; 2015/16; and 2018/2019). Recent hourly data logger data from MW29 also shows an even steeper decline over the summer period. As discussed above evapotranspiration is highest during spring and summer, and this suggests that evapotranspiration and throughflow is the most likely cause of water loss from the ASA as well as potential leakage. The trend in the DBF/BF is likely exacerbated by preferential flow to the mine void as opposed to leakage to underlying aquifers.
- Assuming some diffuse leakage from the ASA to the DBF/BF, with hydraulic properties as detailed in **Table 5-10** and **Table 5-11**, Darcy flux ($q = k(dH/dL)$ suggests this rate to be $7x10^{-5}$ m/d. Assuming the porosity of the underlying formation is 0.13, it would take ~36 years for water to move from the ASA and into the underlying formation.

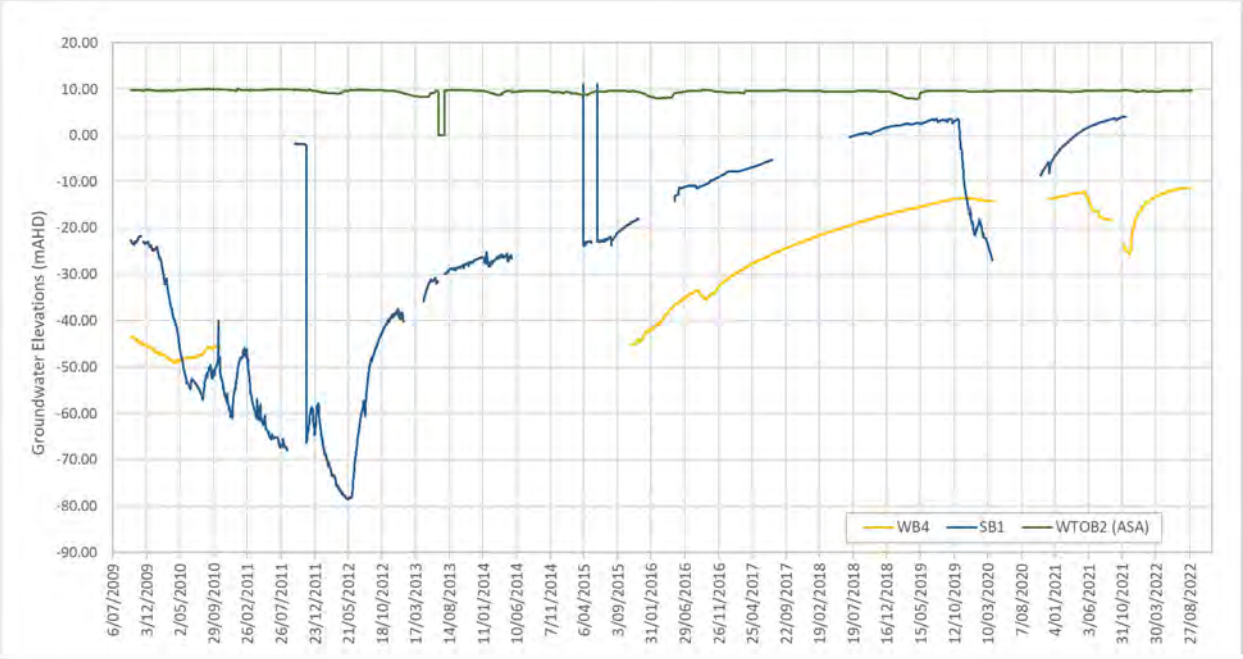

Figure 5-67 WTOB2 (ASA), WB4 (UEVF) & SB1 (LEVF) Nested Hydrographs (SB1 data supplied by Barwon Water)

5.5.4 Upper Salt Creek

Previously documented (Hermon, 2002, Maher, 2011, GHD, 2013 and 2017) key surface water/groundwater interactions that occur are summarised as follows:

- Upper Salt Creek is ephemeral and the UEVF is absent in this area.
- The salinity of the ASA generally ranges between 770 and 1,330 mg/L. The salinity of the LEVF generally ranges between 220 and 300 mg/L and shows low variation over time.
- At the nested site (SV3), the tributary is gaining and losing during different periods throughout the year. During the drier summer periods, the tributary at this site generally becomes losing.
- The Breakfast Creek tributary is baseflow dependent. The extent of the gaining and losing stretch of the tributary will vary over the year, depending on the climatic conditions.
- Upstream of this monitoring location it can generally be concluded that the tributary continues to receive groundwater baseflow over longer periods during the dry months, which is reflected in the perennial flows recorded at this site.
- The consistently low surface water salinity (i.e., 100 mg/L TDS to 300 mg/L TDS) is consistent with stretches of the tributary being a perennial gaining feature.
- The baseflow at this site is from the LEVF aquifer; however, the LEVF is thin in the gully and there is the possibility that there is some contribution to baseflow from the bedrock aquifer which may outcrop in the bed of some upstream stretches of the tributary.

In addition to the above, recent long term water level data presented in **Figure 5-75**, indicates:

- An upward gradient exists from the underling LEVF aquifers to the ASA.
- The hydrographs of the ASA and LEVF show a degree of seasonal fluctuation with groundwater elevation varying by up to 3m in the ASA and 2 m in the LEVF. As the LEVF elevation is higher this would indicate direct rainfall recharge is occurring as opposed to leakage from the ASA.

- Both the shallow aquifers (ASA and UEVF) have shown a stable trend over the last 10 years.
- Stage water level height variations at gauging station SV4 correlate well with the groundwater level fluctuation in the ASA indicating rainfall recharge is the dominant driver of recharge to the ASA. Diffuse recharge is the dominant driver for water level fluctuations in P6 (LEVF).
- Hydrographic recession curves look similar regardless of the timing of the year meaning that groundwater throughflow is the most likely cause of water loss from the ASA in this location as opposed to evaoptranspriation.
- Assuming some diffuse leakage from the LEVF, with hydraulic properties as detailed in **Table 5-10** and **Table 5-11**, Darcy flux (q = k(dH/dL) suggests this to be $4.0x10^{-3}$ m/d. Assuming the porosity of the underlying formation is 0.13, it would take ~0.36 years for the groundwater to move through the 50 m section of clay surrounding Salt Creek.

5.5.5 Lower Salt Creek

Previously documented (Hermon, 2002, Maher, 2011, GHD, 2013 and 2017) key surface water/groundwater interactions that occur are summarised below:

- The behaviour of EC (salinity) at this location compared to higher up in the catchment shows that the swamp evaporates/transpires most attenuated flows, resulting in accumulation of salts in the swamp. These salts are cyclically flushed from the swamp (usually between Jun and Oct), gradually diluting the down-swamp flows (SV2) through 'new' runoff, which mixes with 'older' transpired (higher EC) runoff in the swamp peats.
- The salinity of the ASA generally ranges between 350 and 640 mg/L. This is lower than the salinity recorded upgradient and is likely related to the timing of sampling events. Nearby at UEVF MB07, the salinity of the underling UEVF upper sands is 170 to 200 mg/L. The lower salinity in the upper sands likely reflects the short travel time from its recharge point.
- Significant rainfall across the catchment is required to fill the ASA before flow is seen at the base of Salt Creek (SV2).
- Sufficient low permeability confining layers exist between the permeable parts of the underlying aquifers and surface water, which inhibit interaction between the two.
- Locally around the mine, the UEVF aquifer, has been drawn down due to pumping from the coal mine. However, as between 0.8 GL/yr and 1.8 GL/yr has historically been extracted from the mine sump (**Figure 5-75**), the void itself is likely responsible for creating a local drawdown of the surficial aquifers (DBF) as opposed to dewatering of the UEVF.

In addition to the above, recent long term water level and quality data presented in **Figure 5-75** and **Figure 5-68**, supports the previous conceptual understanding. The lines of evidence for this are:

- Over the last 10 years, the ASA has an increasing water level trend. This is despite:
  - The mine void potentially draining the local area of the DBF/BF; and
  - The localised cone of depression formed in the lower UEVF as a result of historical UEVF extraction from the base of the UEVF.
- The hydrograph in WTOB1 indicates there is no direct connection between the ASA and UEVF lower sands and that the timing and type of rainfall the catchment experiences plus other climate characteristics such as evapotranspiration are the significant inflow/recharge component to the ASA.
- The hydrograph of UEVF MB07 (**Figure 5-58**) shows an increasing trend with no relationship to either the overlying ASA aquifer or the lower section of the UEVF.

- The water quality in UEVF MB07 ranges 170 to 200 mg/L TDS which is significantly fresher than all surface water systems. This suggests that this sand lens is recharged where the sand outcrops and is not influenced by the ASA or surface water.
- Assuming some diffuse leakage from the ASA, through the DBF/BF discharging into the mine water body, with hydraulic properties as detailed in **Table 5-10** and **Table 5-11**, Darcy flux (q = k(dH/dL) suggests this rate to be $4.0x10^{-4}$ m/d. Assuming the porosity of the underlying formation is 0.17, it would take ~29 years for water to move from the ASA and in to the mine water body.

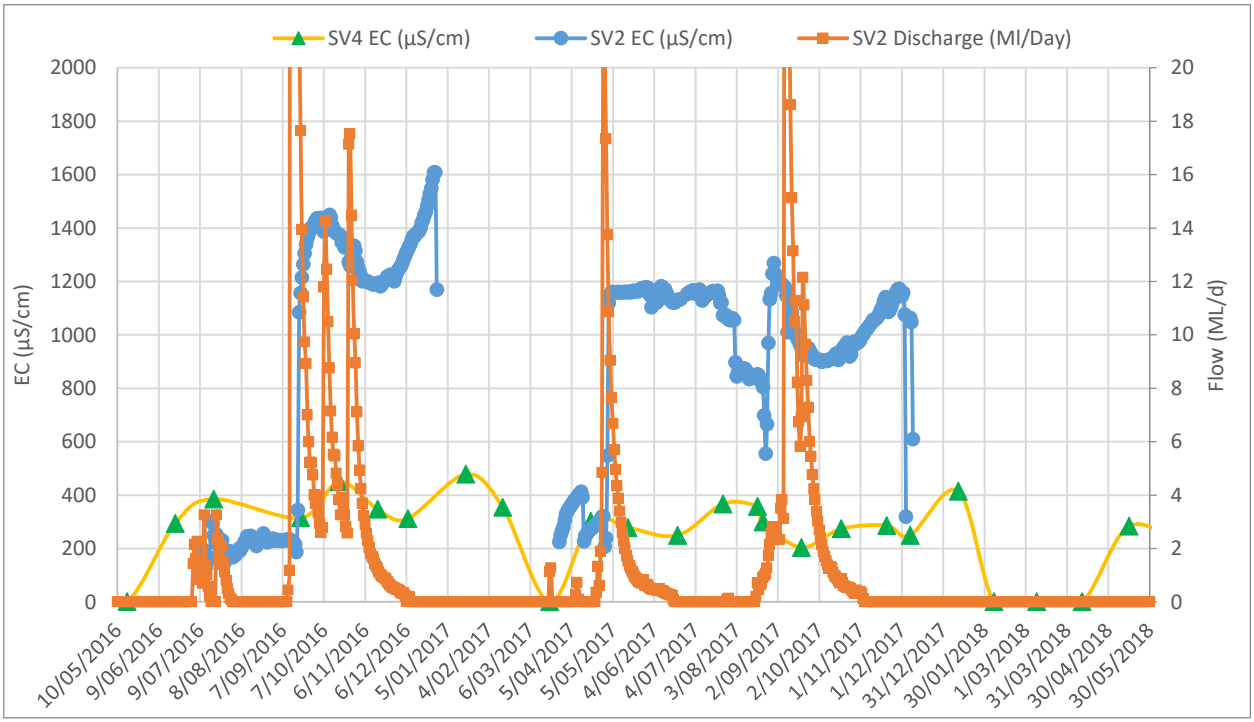

Figure 5-68 Salt Creek Flow and EC (data provided by Barwon Water)

5.5.6 Former PowerStation and Mine Void

As presented in **Section 2**, a significant amount of work has been undertaken at the site over the last 70 years. As the site is highly modified, some of these interactions have been complicated by evolving site activities over time. This has led to a high-level understanding of surface water and groundwater interactions that have been occurring at the site. Much of this understanding is presented in EPA Auditor verification reports (GHD, 2012; EHS Support 2021) and we all documents used in the development of the mine rehabilitation and closure plan (Mining One 2017, EHS Support 2017, 2019).

Within EHS Support 2019, a data gap in the surface water and groundwater interactions was noted in the immediate vicinity surrounding the mine. In response to this eight nested observation bores were installed in the periphery of the mine and data loggers placed in these as well as numerous others located across the former Power Station (refer **Figure 5-69**).

The information presented below is a summary of the current conceptual understanding of the behaviour of surface water and groundwater interactions in the immediate vicinity surrounding the mine.

- The mine void acts as a groundwater sink to the unconfined Boonah Formation.
- An artificial perched water table exists in the DBF sediment underlying the former PowerStation as a result of leaky mine infrastructure.
- The former mixing zone (part of marshy creek) is disconnected from the underlying sediments of the DBF, Boonah Formation with potential losing conditions. However, no evidence of groundwater mounding is observed under this part of the river system suggesting no leakage occurs.
- The water quality in UEVF MB07 ranges 170 to 200 mg/L TDS which is significantly fresher than all surface water systems. This suggests that this sand lens is recharged where the sand outcrops and is not influenced by the ASA or surface water.
- The development of catchment drains (**Section 2.3.2**) diverts local surface water into the mine void. At times the amount of water these drains can add is significant. During January 2022 when the pumping test was inactive, 129mm of rain fell across the mine. This resulted in a water level increase of 0.4m (from -17.9mAHD to -17.5mAHD). From the survey bathometry, this equates to 146ML. Using the surface area of the water body (280,000m^2), this rainfall directly contributed 36 ML (280,000m^2 x 0.129m) meaning the surface drains and groundwater seepage added the rest (110ML). Further calculations on a mine water balance is presented in **Section 5.7**.
- Prior to the exposed coal being covered, small seepage faces after heavy rain were observed near the main coal and basal clay interface leading into the pit void. As coal is unsaturated, its anticipated that its permeability has increased and within the vicinity of the mine, groundwater that would normally be held in the Boonah Formation, now has an easier migration path. This flux will continue to be high until the main coal seam becomes saturated.
- A sampling point located at AV2 has consistently recorded pH between 2.5 and 4 since 1967.
- The Anglesea River estuary had previously been artificially supported by a 3-5 ML/day of approximately pH 7-8 water discharged from Alcoa's power station (EPA License EM32162) at SP3. This discharge ceased in 2016.
- Continuous pressure monitoring data from VWPs from above the main coal seam (in the DBF and Boonah Sands) from 1999 to 2011 (**Figure 5-41**) so no response to drawdown from pumping in the lower sands of the UEVF.

5.6 Wetland/Swamp Conceptual Understanding and Water Balance

5.6.1 Conceptualisation

The generalised cross-section of the ASA is presented in **Figure 5-76**. In this figure the ASA is considered as a perched system with limited connectivity to underlying aquifer systems, having an aquitard (low permeable layer) separating the water within the ASA and underlying groundwater systems (GHD 2013).

To verify this conceptual cross section remains valid in and around the mine and former PowerStation, geological bores located either within or abutting the Alluvial channels have been interrogated. The location of these bores and their geology is presented in **Figure 5-77**. The data used to generate these logs was sourced from The Geological Exploration and Development Information System (GEDIS).

Of the bores interrogated, the results suggest that generalised cross section presented in **Figure 5-76** remains valid with the thickness of the ASA varying from 0.6m to 10m and consisting of organic sand and clay sediments. Underlying the ASA in all bores was a clay layer (highlighted on **Figure 5-77)** which has an average thickness of 3.6m. In all cases this clay is associated with the DBF or the Intermediate coal and clays of the UEVF which has very low vertical hydraulic conductivities.

5.6.2 Hydrodynamics

The principal water inputs to the ASA include rainfall and runoff (runoff either via overland flow or actual surface water flow from upgradient sources). As presented in the previous sections, there is limited connectivity with underlying aquifers by the presence of a low permeability clay base which limits baseflow from or leakage towards the underlying aquifer systems. However, where the ASA is incised within another unconfined aquifer (i.e. the ASA may have eroded through the Boonah Formation), there may be a higher level of side or horizontal component baseflow or leakage where this occurs.

The main discharge components include evapotranspiration and throughflow. The latter occurs when the ASA is fully saturated allowing a greater amount of water to be transmitted through the system. As discussed in the previous sections, water loss via leakage to underlying formations is expected to be negligible due to geological constraints as well as stable and radioactive isotope data indicating there is no connectivity between the ASA and underlying aquifer.

Recent hydrograph data from bores in the ASA also support limited connectivity with underlying aquifers as the steepest decline of groundwater levels occur over spring and summer during those seasons when episodic rainfall events have not occurred (such as spring and summer of 2012/13; 2013/14; 2015/16; and 2018/2019). In these years, the vegetation is transpiring at a greater rate (under higher heat stress) despite the stage height at the gauging station remaining relatively the same at the same point each season, this suggests leakage is not the main factor in water loss. An example of this is shown on **Figure 5-78**.

In addition, the closest bore to WTOB2 is MW29 which is located about 100m away on the edge of the alluvial channel and screened in sand and silt (likely the Boonah Formation underlying or adjacent the ASA). The response observed in this hydrograph shows that the water level change occurs at a far greater rate (both increases and decreases) again indicating two different recharge controls. Water quality differences (TDS) at these locations also suggest there is no connectivity/relationship with the salinity in MW29 (6,900 mg/L) being significantly higher than WTOB2 (2,150 mg/L).

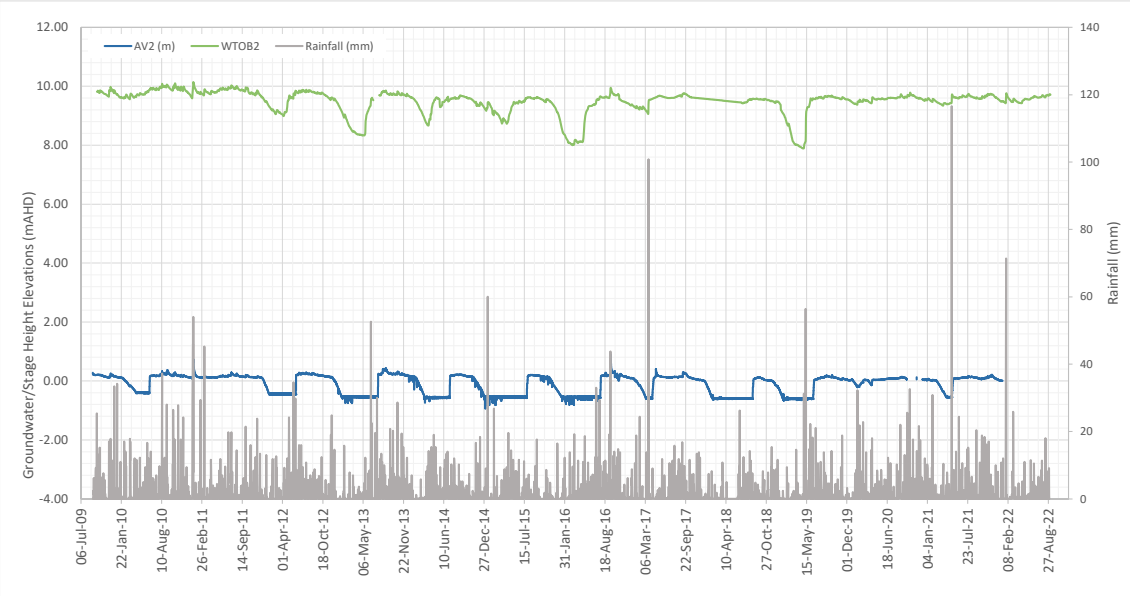

Figure 5-78 Hydrograph of WTOB2 (ASA) and AV2 Stage Height vs Rainfall

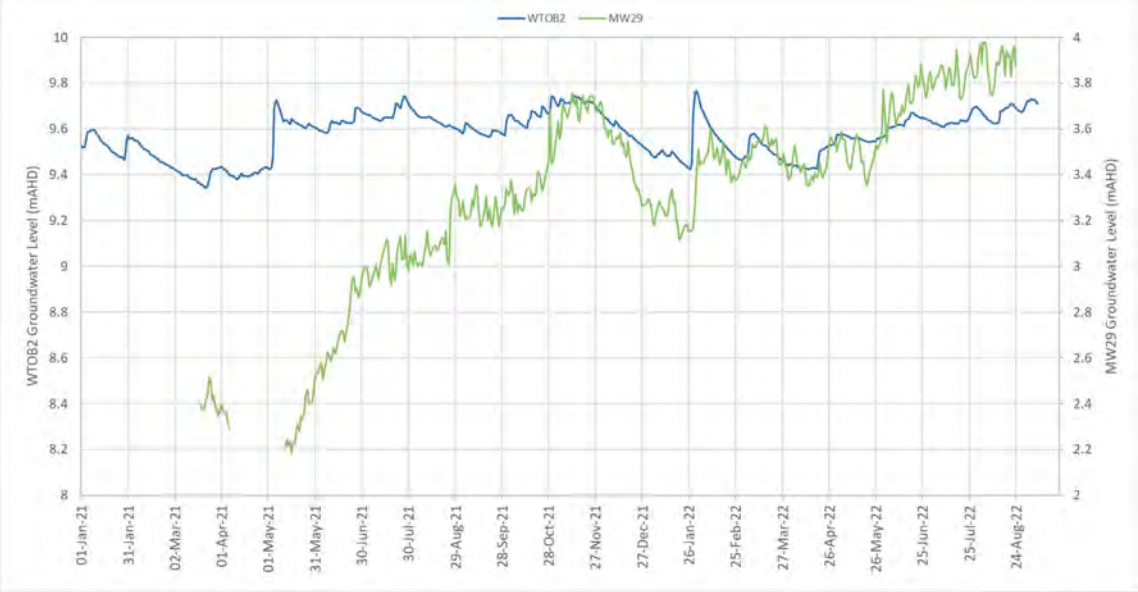

Figure 5-79 Hydrograph of WTOB2 (ASA) and MW29 (Boonah Formation)

Lastly, the (GHD 2013) groundwater model (which is currently being updated) suggested that at pre mine development steady state levels, evapotranspiration consisted of 72% of the discharge water balance across the whole model (Jan Juc GMA). That is 72% of the water entering the model, departed as evapotranspiration. Of this it is expected this would mostly be occurring via the vegetated areas of the marshlands and in the densely vegetated parts of the catchment.

5.6.3 Acidity

Building on from the information presented in **Section 3.5**, catchment acidity is generated when naturally occurring sulphide-bearing sediments, peat and coal (all primarily associated with the mid and lower reaches of the ASA) are exposed to air and oxidised in the vadose zone. This primarily occurs during dry spells and especially during low rainfall springs and summers when evapotranspiration is at its highest. This then causes the water table within the ASA to fall, exposing these sulphidic materials. In subsequent wet periods, these newly oxidised sediments and coal are rewet, completing the oxidisation process, acidifying infiltrating water and runoff. This leached acid is then mobilised via interflow through the ASA or as runoff if the ASA becomes fully saturated and surface waters begin to flow.

To test this concept at a high level within the Anglesea catchment the following will be investigated:

1. Is there evidence of catchment acidity prior to Alcoa activities?
2. Is there a seasonal or climatic impact observed on the historical pH record?
3. Can the timing of rainfall and flow events impact on the frequency and magnitude of acid generation?
4. Are there other contributing factors that can lead to low pH conditions within lower catchment?

5.6.3.1 Historical Catchment Acidity

The first indication comes from the original name of the Anglesea River. Prior to 1884 when the township was established, Anglesea River was originally known as Swampy Creek and as discussed in the sections above, significant acid generating material exists within the swampy/marshy material. Furthermore, in its basic form, acidity reported as pH has been well recorded since the late 1960's both within the estuary and at the location just north of the former PowerStation (where Anglesea River Gauge AV2 is located today, **Figure 5-80**).

The results indicate Upper Anglesea River pH at this location has consistently been low, averaging between 3 and 4 from 1970 to the early 2000's (**Figure 5-81)**. Occasional high pH is seen and this is likely attributed non flowing surface water systems and interaction with the organic matter associated with the alluvial swamps which (along with other processes) can assist in buffering the pH upwards. However, coinciding with the end of the Millennial drought, (2010), surface water pH's have begun to fall. The accepted rationale is again due to naturally occurring sulphide-bearing sediments, peat and coal being exposed to air for longer and oxidised. This primarily occurs during dry spells which causes the water table to fall, exposing these sulphidic materials. In subsequent wet periods, these oxidised sediments become mobile and acidify the water.

Figure 5-80 Location of AV2 and Historical pH Sampling Point

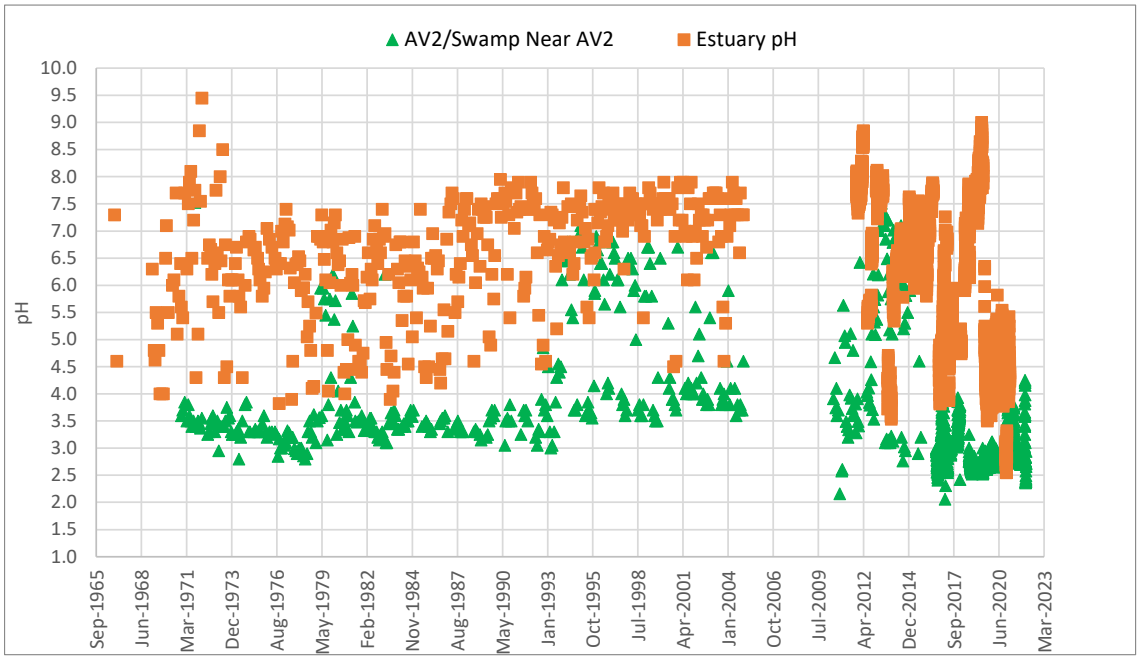

Figure 5-81 Historical pH (Data Source: Pope 2010; WMIS 2022)

5.6.3.2 Can a Seasonal or Climatic Trent be Observed on Historical pH

As it is understood that dry spells have the potential to cause acid accumulation and the subsequent wetter periods then mobilise these metals, it should be reasonable to assume historical climatic trends may also show a similar relationship.

It can be seen on **Figure 5-82** that coinciding with the start of the Millennial drought, (mid 1990's), surface water pH's have begun to fall. In addition, and interestingly, a cubic function was applied to the dataset for AV2. A cubic function was applied as there are 3 real roots seen in the long-term rainfall behaviours (i.e. crosses the x -axis 3 times (refer **Figure 3-3**)). The trend of this function matches closely with the annualised rainfall surplus and deficit which may give an indication that climate (rainfall) and catchment pH have some dependency.

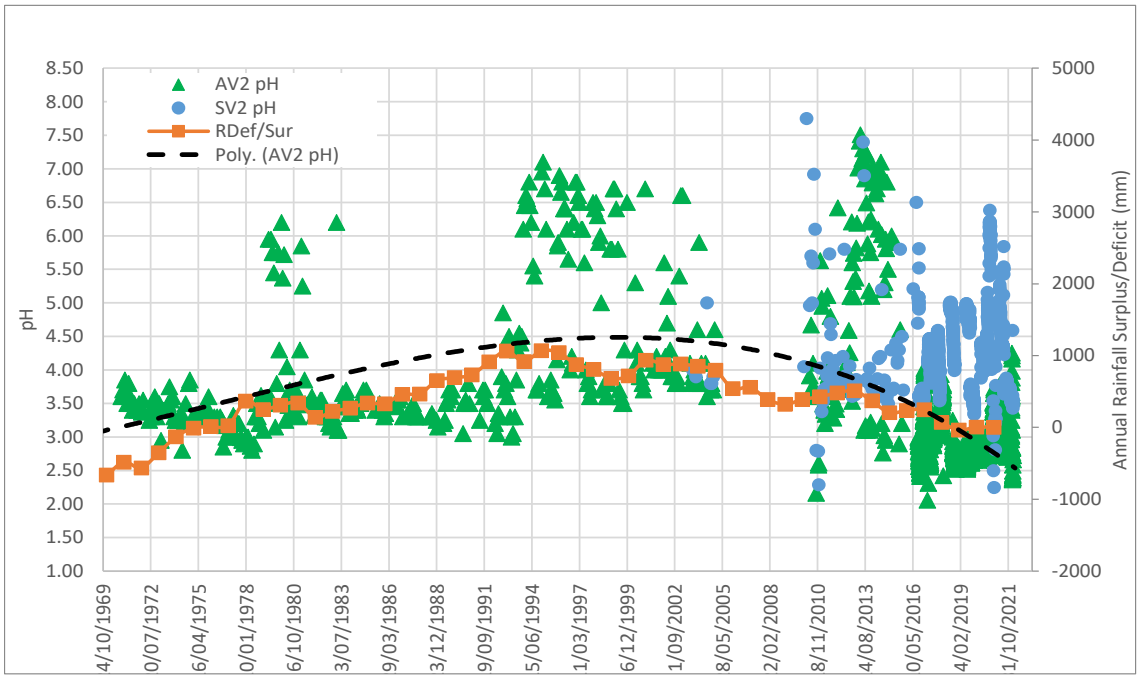

Figure 5-82 Historical pH and Climate (Annual Rainfall Surplus / Deficit)

5.6.3.3 Is Timing and Magnitude of Climatic Factors Important?

It is evident from the section above that low pH conditions have occurred in this location over the last 50 years. Knowing that acidic flushes by way of EPA recorded fish kill events occurred in 2010 and 2016 (**Figure 5-86)**, we can see that the corresponding pH at AV2 was 2.6. Interestingly this corresponds to the 5th percentile of rainfall. These events are denoted on **Figure 5-83** and **Figure 5-84** with **Table 5-12** listing the historical dates that pH has dropped below 2.6 as well as the preceding climate indicators.

With the exception of the low pH measured during March 2017 and February 2018 (these were measured when no flow occurred), it can be observed that leading up to these conditions, AV2 has recorded no flow for ~3 months or more, with the average flow cessation period being 180 days. Therefore, based on this high-level observation it can be conceptualised that flow cessation events of 180 days or more, significantly increase the likelihood of low pH conditions being experienced.

However and referring to **Figure 5-84,** it can also be seen that there have been multiple periods where the no flow period has been greater than 180 days and the following "first flush" pH have not dropped below 2.6 (e.g. In 2014 and 2015). In these years, the pH did fall to below 3 but the causal flow was significantly lower in magnitude than the other noted events.

This then gives us an indication that the timing of no flow events is as important as the magnitude of the flow event itself. Again referring to **Figure 5-84**, it can be observed that when the no flow period roughly exceeds 180 days and the magnitude of the first flows is >5 ML/day, these significant low pH conditions are observed.

In addition to this **Figure 5-86** presents 5-year cumulative rainfall totals against the long-term average (1900 to current) and the EPA notification of fish kill events within the Anglesea River estuary. Looking back at over the last 50 years of data it is clearly evident that rainfall totals have decreased and there is a clear correlation between the occurrence of acidification events (fish kills) during successive years of below average rainfall. In fact, from 122 years of data, the period 2005 to 2009 was the driest 5-year period on record (worse than millennial drought) resulting in a 24% reduction of annual rainfall. More recently, the period 2014 to 2018 represents the 2nd driest 5-year record on record resulting in a 21% rainfall reduction.

Table 5-12 Notable Low pH Conditions at AV2

Daye	pH	# days prior no flow	Preceding 3-month Rainfall (mm)	Peak Flow Rate (ML/day)
20/10/2010	2.16	137	319.2	14.80

5.6.3.4 Other Factors That Could Have Led to Low pH Conditions within Lower Catchment?

That catchment has always reported low acidity and whilst the above gives an indication that naturally occurring conditions within the catchment and climate is the most sensitive driver to lower catchment acidity, there are other potential causal pathways. Each along with their likelihood level of impact is explained below:

1. Coogoorah Park and River Mouth Changes and Management

   The head of the estuary branches in two main channels, the main channel and Coogoorah Park. The latter comprises a series of smaller channels constructed following the 1983 Ash Wednesday fires to flood smoldering peat. The development of Coogoorah park introduced a significant quantity of acid sulfate soils to the environment as well as requiring modification of the estuary mouth to maintain water levels. A study by Federation University (Sullivan *et al.,* 2016) showed that the acidification hazard posed by acid sulfate soils is almost entirely contained within Coogoorah Park and not the low-lying land on the south-eastern side of the bridge location at Anglesea and therefore likely impacts on the Estuary water quality.

2. Historical Mining Operations

   a. Alcoa EPA licenced discharge of ~ 4.5 ML/day Alkaline pH water; pH ~7 - 8, to the Lower Anglesea River.

      As presented on **Figure 2-1**, the licenced discharge of Alkaline water clearly shows the alkaline buffering capacity this discharge baseflow had on the pH of the Estuary. This discharge ceased in March 2016. With Climate beginning a drying phase since the late 1990's, the Estuary has to respond extremely quickly to this new normal as opposed to being able to response naturally over the last 20-25 years if the buffering flows were absent.

   b. Mining

      It is acknowledged that as the mine was progressively established, the local mine catchment surface water runoff that would have previously ran-off into a small section of Salt Creek was diverted away either into the mine or towards the former mixing zone low point. This activity may have led to a minor reduction of over land flow that would have recharged the ASA to maintain saturation of the sulfidic materials in this small reach of Salt Creek. However, it is anticipated that this disturbed area would only represent a very small part of the Salt Creek flow network and as this is at the end of the catchment, no measurable change in water quality likely to be observed.

   c. Groundwater Pumping

      Potential does exist whereby the long-term groundwater pumping from the UEVF and other aquifers may have caused leakage from the surface water systems and thus increasing the wetting and drying frequency of the ASA. As discussed throughout this report, all lines of evidence suggest UEVF groundwater extraction is unlikely to have resulted in leakage from the ASA into the UEVF aquifer.

5.7 Mine Catchment Water Balance

This section presents a high-level overview of the mine water balance.

5.7.1 Groundwater Contribution

The groundwater contribution into the former mine void (baseflow) can be complicated to determine in complex environments; however, Alcoa has historically installed a sump pump into the base of the mine void. As the mine acted as a groundwater sink, this pump extracted both groundwater inflow and surface runoff and as such can be used to calculate the total water input. As shown on **Figure 5-75**, the average water extraction from the sump was on average 1,242 ML/yr (3.4 ML/d) for the period 1998 to 2014. This reduced to 884 ML/yr (2.4 ML/d) in the later period of the mine development when the rate of inflow was more realistic of the current and final mine bathymetry. It is also noted that a portion of this volume would also be in-situ groundwater as mine sumps are typically placed 1 m below the surface to ensure dry conditions. This component can is estimated to be between 1 and 1.9 ML/d based on the surface area of the sump and a porosity ranging between 5 and 10 percent.

Taking this into consideration, the baseflow component entering the mine void is approximately 0.46 to 1.4 ML/d or 170 to 520 ML/yr. As groundwater pressures recover, this rate will increase.

5.7.2 Evaporation

As presented in **Section 3.2.1**, evaporative losses (rainfall deficit) per year were estimated at 311 ML/yr for a full water body however this is likely to be a under estimate. Under a drying climate, this is expected to increase closer to 500 ML/yr.

5.7.3 Rainfall and Runoff

To estimate the surface water component, direct rainfall was multiplied by the surface area of the water body. Runoff was calculated by working out the residual volume is would take to increase the water level after considering the groundwater components, rainfall and evaporation.

On occasion, significant surface water input can be achieved due to the installation of nine catchment drains in 2020 (**Section 2.3.1**). For example, on 4 May 2021, Airies inlet recorded 116.6 mm, with a rain gauge at the mine site recording 86 mm. This rainfall event caused the pit water level to rise by 0.2m with an estimated 159ML being contributed by runoff. Alluvium Consulting (pers comm.) calculated this event as a 1 in 2000 Annual Exceedance. Probability (AEP) event.

5.7.4 Budget

Assuming no other inputs (such as surface water diversion) or extractions, the resulting water balance is presented on **Figure 5-87** and is based on:

- Groundwater inflow averaging 24 ML/month (est. 0.8ML/d from old sump pumping records).
- Monthly rainfall records.
- Groundwater Pumping test discharge volumes.
- Evaporation raging 15 ML/month (winter) up to 41 ML/month (summer) or 354 ML in 2021.

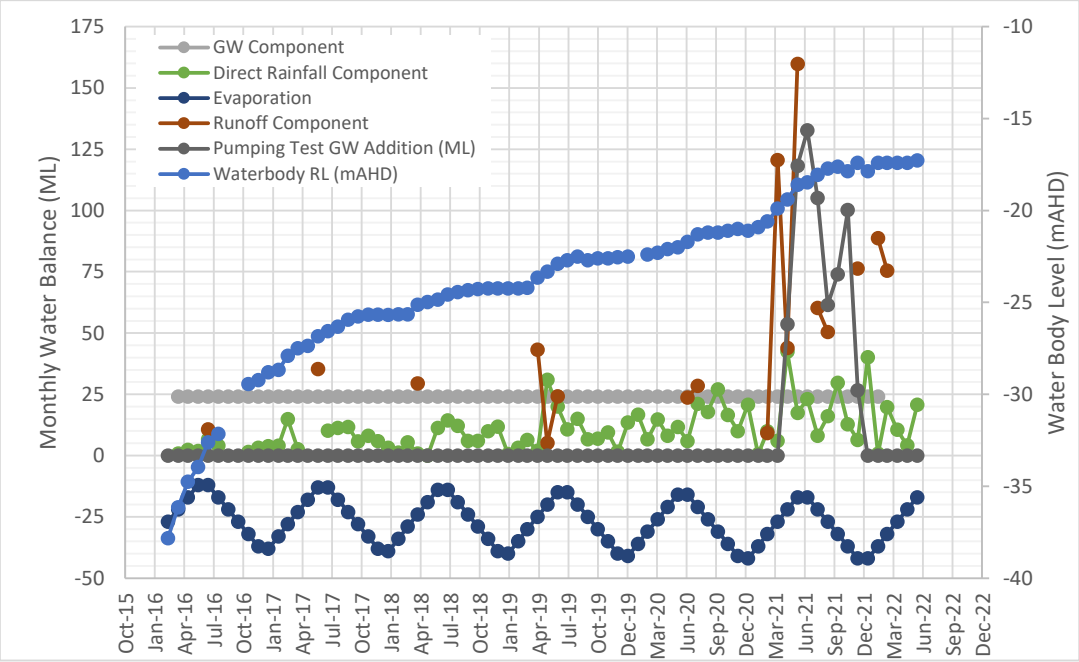

Figure 5-87 Monthly Mine Water Balance

6 Summary of the CHM

The following provides a summary of the conceptual hydrogeological (and hydrological) conditions.

6.1 Climate

Long-term average annual (LTA) rainfall at Wensleydale is 769 millimetres per year (mm/yr) based on data from 1935 to current. At Aireys Inlet, the LTA is 616 mm/yr based on data from 1994 to current. Mean annual potential evaporation (PE) does not vary significantly across the region, with an annual mean of 1,300 mm measured at Anglesea.

Over the last 120 years there have been 3 distinct climatic phases, that is:

- Between 1900 and 1950, the region exhibited a drying climate.
- Between 1950 and 1990, the region then experienced a strong wet period.
- Since 1990, a prolonged drying period is being observed. The millennial drought (late 1996 to mid-2010) occurs in this period and more recently the 5-year rainfall totals of 2004 to 2009 and 2014 to 2018 comprise the 2 driest 5-year totals on record for the region.

Future median climate projections estimate:

- Potential evapotranspiration is projected to increase by 3.7% by the Year 2040, and 6.4% by 2065 relative to the current climate baseline.
- Average annual rainfall is projected to decrease by 3.6% by year 2040 and 5.8% by 2065.
- By the 2030s, sea level is projected to rise by around 12 cm a under medium emissions scenarios. By the 2070s increases of around 32 cm are modelled. Victorian planning guidelines plan doe rises of 0.8m by 2100.

6.2 Surface Water and Catchment Acidity

The key conceptual learnings are:

6.2.1 Surface water

- The major waterways Anglesea River/Marshy Creek and Salt Creek are ephemeral; however, there are several non-groundwater fed, permanent pools that exist across its reach. These are recharged by overland / surface runoff and located in densely vegetated parts of the Alluvial Swamp system.
- The surface water that flows in the catchment is retarded in Alluvial Swamps located in the mid and upper parts of the catchment. These alluvial swamps store and use (via evapotranspiration) significant volumes of water. The water that is stored in these systems is referred to as groundwater of the alluvial swamp aquifer (ASA). When the ASA storage is fully saturated and / or runoff exceeds the ASA's storage capacity, surface water flows begin.
- The pH at SV2 generally ranges between pH 3.5 and 4. Further up the Salt Creek catchment at SV1, the pH is higher ranging between pH 5 to 7. The lowering of the pH in the mid and lower reaches of the catchment is due this section containing more ASS which is readily oxidised.
- Longer term pH data at or near location AV2 shows pH generally ranging between 3 and 4 since 1969, however since the onset of drier conditions since the late 1990's the pH is now usually less than pH 3 (net acidic). At AV1 (top of the catchment), is generally pH >5. As with

Salt Creek, acidity increases downstream where the mid and lower reaches of the catchment containing more ASS which is readily oxidised.

- EC at the lower end of Salt Creek at SV2 generally ranges between 250 and 2000 µS/cm), whilst in the upper part (SV4) this range is more constrained varying from 199 and 312 µS/cm.
- The EC in Upper Anglesea River/Marshy Creek at AV1 generally ranges between 500 and -1,000 microSiemens/centimetre [µS/cm]) and is lower than EC measured downstream at AV2 which ranges between (2,000 and 7,000 µS/cm).
- In both sub catchments, the larger variation in EC seen in the downstream part of the catchment is likely due to surface water flows being retarded in the Alluvial Aquifer and allowing evapotranspiration to concentrate salts.
- The majority of the water samples plot as a sodium chloride (NaCl) water type. The dominance of this water type is most likely related to the depositional environment of the Eastern View Formation (sub-littoral) and the geochemical influence on the younger aquifer sediments of the Demons Bluff and Boonah Formations.
- Since surface water monitoring began in 1967, Salt Creek has experienced a significant decline is annual flow. This decline is primarily related to climate although it is acknowledged that as the mine was *progressively established, local mine catchment surface water runoff that would have previously ran-off into Salt Creek was diverted away either into the mine or towards the former mixing zone low point. Its anticipated that this disturbed area would only represent a very small part of the Salt Creek flow network.*
- At the lower reaches of the Anglesea River catchment in the region of the site and downstream, flows had previously been artificially supported by a 3-5 ML/day of approximately pH 7 water discharges from Alcoa's power station (EPA License EM32162). This ceased in 2016.
- Within the mine void, evaporative losses per year are estimated at 311 mm/year.

6.2.2 Acidity

- An acid sulfate soil assessment undertaken within the Anglesea swamp by Fiona Glover and Assoc and Prof. John Webb (Report on Anglesea River Acid Sulfate Soils, April 2013) identified both potential (PASS) and actual acid sulfate soils (AASS) were present within the sediments. Wong et al., (2020), also found the catchment to contains high sulfur reserves from pyritic shales and siltstones, coal seams, tea tree swamps.
- The ASA contains naturally occurring sulphide-bearing sediments, peat and coal. As the water level fluctuates in the ASA these sediments are exposed to air and oxidised in the vadose zone. This happens over and over again resulting in a build-up of leachable acid and metals. When the ASA becomes fully saturated (usually after a significant wet period), these oxidised sediments are mobilised resulting is low pH (acidic) water. Usually, the longer the period between flow events, the lower the resulting pH flow is.
- The Upper Anglesea River has experienced low pH events prior to Alcoa. A sampling point located at AV2 has consistently recorded pH between 2.5 and 4 since 1967.
- A good statistical correlation exists between rainfall surplus and deficit trends and catchment acidity (pH) indicating that climate (rainfall) and catchment pH have some dependency.
- The Anglesea River estuary had previously been artificially supported by a 3-5 ML/day of approximately pH 7 water discharged from Alcoa's power station (EPA License EM32162). This discharge ceased in 2016. This along with the introduction of Cooroogarah park and the management of the estuary mouth have contributed to the variability in water quality seen in the Estuary over time.

- 12 km further south at Airies Inlet, Distillery Creek (a tributary of Painkalac Creek) has also reported frequent low pH conditions (Surf Coast Shire, 2006). Therefore, climatic drivers as opposed to anthropogenic factors (such as groundwater pumping) are understood to be the main reason for the low pH conditions experienced within the catchment.

6.3 Surface Water and Groundwater Interactions

Throughout this report multiple lines of evidence have been presented which gives the reader a greater appreciation of how surface water and groundwater moves and interacts through the catchment. This section summarises these lines of evidence.

Previously geological and hydrogeological evidence has indicated that the swamps and marshlands that make up the ASA act like a PWT (that is water in the ASA finds it very difficult to interact (leak or receive baseflow) with underlying aquifers). In summary these lines of evidence are:

- A review of all available exploration geological bore logs (22 logs) that were located either within or adjacent to the ASA shows that an average thickness of 27.7m (max = 86m; min = 2.4m) of either clay or silt (e.g. low permeability material) that separates the base of the alluvial / swamp sediments in which surface water flows to the next most permeable layer underlying the surface water systems.
- Laboratory testing of some of these low permeability materials indicated that the average vertical hydraulic conductivity was 0.0002 m/d with an average porosity of 41%. To put this in context, assuming a minimum thickness of 2.4m existed between the base of the swamp sediments and the next most permeable formation, surface water would need to be present for 5.6 years for water to leak though this barrier. As we know, the water ways are ephemeral and this driving head of water is rarely there for more than a few months at a time.
- Throughout the marshland areas several permanent water pools have been mapped (AGP1-B, AGP2 and ASP7). Stable and radioactive isotopes obtained within these pools indicate that they are not in direct connection with the underlying aquifers and therefore not baseflow dependant. At these locations there is an upward gradient. If the gradient were to reverse, as the impermeable base of the ASA inhibits baseflow, there is no reason to suggest it won't do the same and inhibit leakage.
- All ASA monitoring bores have shown a stable trend over the last 10 years with no impact seen in either system despite Alcoa extraction up to 2016 and more recent aquifer tests, and also aquifer tests undertaken by Barwon Water between 2009 and 2012. In fact, for reason unknown, the bore WTB02 in the lower part of salt creek ASA shows variable but overall increasing trend over the last 10 years.
- Most large rainfall events exceeding 40mm have resulted in an immediate increase in groundwater levels within most ASA monitoring locations. This indicates that direct rainfall recharge is the dominant driver of recharge to the ASA.
- Within the ASA, the steepest decline of groundwater levels occurs over spring and summer when episodic rainfall events are absent (such as spring and summer of 2011/12; 2013/14; 2015/16; and 2019/2020). This similar correlation is not commonly observed in unconfined aquifers surrounding the ASA such as the outcropping UEVF and BEF. As evapotranspiration is highest during spring and summer, this suggests that evapotranspiration and throughflow is the most likely cause of water loss from the ASA.

6.4 Hydrogeology

Beneath the site there exists an extensive and complex series of aquifers and aquitards. These are:

- Alluvial Swamp Aquifer
    - An unconfined aquifer comprised of alluvial sediments and organic clay and peaty mix. This aquifer sits in the bottom of incised valleys where over thousands of years erosion occurred through the surrounding sediments before hitting an impermeable base. Infilling of these channels now forms the base material of this aquifer.
    - Groundwater within this aquifer has limited connectivity with underlying formations due the presence of a low permeability clay at its base. Hydrographic analysis as well as water chemistry using stable and radioactive isotopes also suggest limited potential for surface water and groundwater interactions to occur.
    - Several non-baseflow dependant permanent pools supporting high value ecology are found in the mid and upper reaches. These pools are located in heavily vegetated parts of the catchment.
    - Rainfall and runoff are the dominant recharge driver and evapotranspiration and through flow is the dominant discharge driver.
    - The average TDS generally increases as you travel down the system with TDS in the upper part ranging from 569 mg/L (Upper Salt Creek WTB01) and 1082 mg/L (Upper Anglesea River WTB03) to 2024 mg/L at WTBO2. This occurs due to the longer travel time water have with the sediments it passes though as well as evapotranspiration assisting in salt accumulation.
    - A review of the aerial imagery along with ecological reports (Ecology Australia 2007, 2011, 2012, 2013a,b) indicates swamp vegetation and associated ecology has persisted. Coupled with persistent and stable groundwater levels in WTOB1 and WTOB2 suggests the ASA has remained saturated over the long term.
- Demons Bluff and Boonah Formation
    - The Demons Bluff Formation consists siltstone, clay, sandstone and minor coal seams. At the former Power Station site the DBF is extends from the surface to ~10m below ground level. It thickens and dips towards the southeast.
    - The Boonah Formation consists clean sandstone with minor shale, clay and coal. The Boonah Formation underlies the DBF and is ~25m thick.
    - The mine void acts as a groundwater sink and most observation bores surrounding the mine screened in this formation are unsaturated.
    - Permeability tests undertaken within this formation are highly variable with an average horizontal hydraulic conductivity (0.1 m/d, from slug tests) and vertical hydraulic conductivity of $1x10^{-4}$ m/d, from laboratory analysis). Note the vertical permeability tests target bores with a higher clay content, whilst the slug tests targeted bores that had a greater potential to transmit water.
    - The recharge potential of outcropping sediments is low as evidenced by a lack of water table response after heavy rainfall.
    - TDS in the DBF aquifer from the recent groundwater monitoring event in 2020 ranges between 578 mg/L and 6,660 mg/L with an average of 2,519 mg/L. The TDS from most wells is classified as Segment B or higher.
    - In the vicinity of the mine, the only monitoring bore that was saturated was DBF MB06 with an average TDS of 2,770 mg/L. This bore is installed within the backfilled overburden material and as such is not representative of the native aquifer.

- Upper Eastern View Formation
    - The UEVF consists of clay, silty clay, silt and fine to medium-grained sand sequences with minor fine gravel lenses. Brown coal is also common throughout the UEVF especially in the top half.
    - The UEVF is represented by multiple aquifers occurring as sand lenses separated by aquitards (clay and coal). In the upper half, there is significantly more clay and coal, whilst more permeable sand lenses exist near the base. These basal sand lenses were the target of Alcoa's historical extraction.
    - Pre mine levels suggested the potentiometric surface for the UEVF lower sands was ~4m AHD. Individual sand sequences above this within the UEVF showed slightly lower potentiometric surfaces the shallower the sand lenses occurred.
    - Vertical permeability testing of these clays and coal indicated an average vertical hydraulic conductivity of $1x10^{-4}$ m/d. Analysis of the pumping test Stage 1 results suggest the horizontal hydraulic conductivity is 1.3 m/d and a storativity of $4x10^{-4}$ (-).
    - A single packer test was attempted to define the hydraulic parameters of an upper sand lens. After ~250L of water was injected, the packer failed indicating some upper sand lenses may not be laterally extensive. Historical bore logs also indicate these upper sands may not fully interconnect.
    - Groundwater quality is variable with shallower sand sequences with the TDS within the upper sands is variable ranging from 168 mg/L (UEVF MW07) to 3,470 mg/L (UEVF MW04) with a median concentration of 889 mg/L. This provides further evidence that these lenses may be discontinuous.
    - In the lower sands, during the groundwater pumping test pH ranged from 6.3 to 6.7 with a mean of 6.5. The TDS ranged from 741 to 1,660 mg/L which is consistent with historical ranges reported prior to May 2021, of between 830 to 1,313 mg/L.
    - Based on Stage 1 of the pumping test, the estimated transmissivity ranged from 58.2 to 114.2 m^2/day (hydraulic conductivity range of 0.8 to 1.6 m/day) and a storativity range of 2×10^{-4} to 5×10^{-4}.
- Middle Eastern View Formation
    - The MEVF underlies the UEVF and generally consists of 30-40m of mudstone and siltstone, but also has minor sand and gravel lenses as well as thin brown coal layers.
    - It has been previously modelled as a leaky aquitard as depressurisation impacts have been observed in some deep Alcoa UEVF observation bores whilst pumping has been occurring from nearby the LEVF extraction bores. However, a recent bore assessment program involving down hole camera and wireline logging was undertaken by Alcoa to identify bores with potential integrity issues or those that may cross screen aquifers. In 2021, several at-risk bores were identified and decommissioned. Since the restarting of the LEVF extraction by Barwon Water in early 2022, no depressurisation impacts have been recorded in the Alcoa UEVF deep observation bores. This indicates that the aquitard may not be as leaky an initially thought with these previous bores acting as preferential flow conduits.
- Lower Eastern View Formation
    - The LEVF forms a confined to semi-confined aquifer (in the upper parts of the catchment) across the region and consists of unconsolidated micaceous silts, carbonaceous clays, silty clays, thin brown coal seams and fine to coarse-grained sands and gravels. Below the coal mine site, the LEVF is up 200 m thick where aquifer material occurs within geological synclines. Geologically, this unit represents the Pebble Point Formation and, prior to Barwon Water groundwater extraction in the area, was artesian at the site.

    - Groundwater quality (TDS) in the LEVF is fresher than that observed in the UEVF. GHD (2013) reported that groundwater salinity had been measured between approximately 500 to 900 mg/L TDS.
    - The aquifer parameter data suggests transmissivities of up to 330 m^2/day and hydraulic conductivities of up to 2.77 m/day can occur in individual sand horizons.
- The Mine Void
    - In addition to the hydrogeological units above, the mine void acts as a hydrogeological control. For the local catchment, the mine void acts as a groundwater sink.
    - Prior to the exposed coal being covered, seepage faces after heavy rain were observed near the main coal and basal clay interface leading into the pit void. As coal is unsaturated, its anticipated that its permeability has increased and within the vicinity of the mine, groundwater that would normally be held in the Boonah Formation, now has an easier migration path. This flux will continue to be high until the main coal seam becomes saturated.
    - TDS are observed to vary between 1,200 and 2,200 mg/L and this appears to be influenced by increases in major ions particularly sulfate. Prior to the pumping test, the median pH of the water body was 3.35. At completion of the Pumping test after ~670ML of UEVF Lower Sand (pH 6.5 median) groundwater was placed into the void, the median pH rose slightly to 3.53.

7 Assumptions and Limitations

EHS Support has prepared this report in accordance with the usual care and thoroughness of the consulting profession for the use of Alcoa Australia and only those third parties who have been authorised in writing by Alcoa of Australia. It is based on generally accepted practices and standards at the time it was prepared. No other warranty, expressed or implied, is made as to the professional advice included in this report. It was prepared having regard to the purpose for which Alcoa Australia is intending to use this report and having regard to the purposes in accordance with the scope of work.

The sources of information used by EHS Support are outlined in this report. EHS Support has made no independent verification of this information beyond the agreed scope of works and EHS Support assumes no responsibility for any inaccuracies or omissions.

This report was prepared between December 2021 and September 2022 and is based on the conditions encountered and information reviewed at the time of preparation. EHS Support disclaims responsibility for any changes that may have occurred after this time. This document and the information contained herein should only be regarded as valid at the time of the investigation unless otherwise explicitly stated in this report.

This report should be read in full. No responsibility is accepted for use of any part of this report in any other context or for any other purpose or by third parties. This report does not intend to give legal advice. Legal advice can only be given by qualified legal practitioners.

This report contains information obtained by inspection, sampling, testing or other means of investigation. This information is directly relevant only to the points in the ground where they were obtained at the time of the assessments. The borehole logs indicate the inferred ground conditions only at the specific locations tested. The precision with which conditions are indicated depends largely on the frequency and method of sampling, and the uniformity of conditions as constrained by the project budget limitations. The behaviour of groundwater is complex. Our conclusions are based upon the analytical data presented in this report and our experience. Future advances in regard to the understanding of hydrogeological and other relevant environmental conditions and their behaviour, and changes in regulations affecting their management, could impact on our conclusions and recommendations.

Where conditions encountered at the site are subsequently found to differ significantly from those anticipated in this report, EHS Support must be notified of any such findings and be provided with an opportunity to review the recommendations of this report.

Further, the objectives and scope regarding hydraulic testing, groundwater sampling and gauging and bore drilling, logging, completion and decommissioning have been directed by requests from Alcoa Australia. EHS Support disclaims responsibility for any influences these requests may have had on conclusions within this report.

COPY OF RECORD IN THE VICTORIAN WATER REGISTER

TAKE AND USE LICENCE

under Section 51 of the Water Act 1989

The information in this copy of record is as recorded at the time of printing. Current information should be obtained by a search of the register. The State of Victoria does not warrant the accuracy or completeness of this information and accepts no responsibility for any subsequent release, publication or reproduction of this information.

This licence does not remove the need to apply for any authorisation or permission necessary under any other Act of Parliament with respect to anything authorised by the take and use licence.

Water used under this entitlement is not fit for any use that may involve human consumption, directly or indirectly, without first being properly treated.

The Authority does not guarantee, by the granting of the licence, that the licensee will obtain any specific quantity or quality of water. The Authority is not liable for any loss or damage suffered by the licensee as a result of the quantity of water being insufficient or the quality of the water being unsuitable for use by the licensee at any particular time or for any particular purpose.

This take and use licence entitles its holders to take and use water as set out under the licence description, subject to the conditions that are specified.

Licence Holders

Alcoa Of Australia Ltd**

Licence Contact Details

Alcoa Of Australia Ltd** CAMP ROAD ANGLESEA
VIC 3230

Licence Description

Expiry date	30 Jun 2024
Status	Active
Authority	Southern Rural Water
Name of waterway, aquifer or works	LTA-Jan Juc
Water system type	Groundwater
River basin or groundwater unit	Jan Juc (GMU)
Licence volume	4000.0 megalitres
Licence volume adjusted for temporary trade	4000.0 megalitres
Method of taking	Direct extraction from Groundwater
Period during which water can be taken	01 Jul - 30 Jun inclusive
Use of water	Industrial or commercial use - as well as domestic and stock use
Trading zone	Jan Juc LTA

Licence Volume Details

Licence volume	4000.0 megalitres
Licence volume adjusted for temporary trade	4000.0 megalitres

Temporary volume transaction details

Approval date	*Volume traded (ML)*	*Expiry date*
Nil		

Extraction Point Details

Easting	*Northing*	*Zone MGA*	*Location description*
Nil			

Land on which the Water is to be Used

Crown allotment description

Allotment	*Portion*	*Section*	*Township*	*Parish*
64D				Jan Juc

Property address

ANGLESEA POWER STATION CAMP RD ANGLESEA 3230

This entitlement may be transferred to another parcel of land, if application is approved by the Authority.

Related Instruments

Conditions

This take and use licence is subject to the following conditions:

Method of taking

1 Water may only be taken under this licence if it is taken by the methods expressly approved by this licence.

2 The licence holder must at all times provide the Authority with safe access to inspect all works and appliances used to take water under this licence.

Take location

3 Water may only be taken under this licence if it is taken at the location described as follows: the land parcels identified on this licence.

Take volume and rate

4 The volume of water taken under this licence in any twelve-month period from 1 July to 30 June must not exceed the licence volume, less any volume that has been temporarily transferred to another person or location.

5 The maximum volume that may be taken under this licence in any one day is 39.8 megalitres per day shared between 7 bores.

Temporary transfers to the licence holder

6 If there has been a temporary transfer of another licence to take water at the location, and use water on the land, specified in this licence: a) the extra volume of water taken must not exceed the volume transferred, and b) all the conditions of this licence apply to the taking and using of water consequential to the transfer.

Rosters and restrictions

7 When directed by the Authority, water must be taken in accordance with the rosters and restrictions determined by the Authority, and advised to the licence holder.

Metering of water taken and used

8 Water may only be taken under this licence if it is taken through a meter approved by the Authority.

9 Meters must be installed , in accordance with the specifications set by the Authority, at the licence holder's expense.

10 Meters used for the purpose of this licence are deemed to be the property of the Authority.

11 The licence holder must at all times provide the Authority with safe access to meters for the purpose of reading, calibration or maintenance.

12 The licence holder must notify the Authority within one business day if the meter ceases to function or operate properly.

13 The licence holder must, if required by the Authority, keep an accurate record of the quantity of water taken under this licence and allow the Authority to inspect this record at all reasonable times, and provide a copy of the record when requested.

14 The licence holder must not, without the consent of the Authority, interfere with, disconnect or remove any meter used for the purposes of the licence.

15 The Authority may, if it deems necessary, make an estimate of the total volume of water taken under this licence.

Use of water

16 Water taken under this licence may only be used on the land, and for the purposes, specified in the licence.

17 The licence holder must at all times provide the Authority with safe access to inspect the land on which water is licensed to be used.

Operation and maintenance

18 The licence holder must keep all works, appliances and dams associated with this licence,

including outlet pipes and valves, in a safe and operable condition, and free from obstacles and vegetation that might hinder access to works.

Preventing pollution

19 The licence holder must, construct and maintain bund walls around any hydrocarbon-fuel-driven engine, motor, fuel storage, or chemical storage used in connection with this licence, in accordance with the timeframe, specifications, guidelines and standards prescribed by the Authority.

Managing groundwater infiltration

20 The maximum volume of water that may be applied to the land referred to in the licence in any 12-month period from 1 July to 30 June is the annual use limit which is equal to the licence volume, or if the annual use limit is adjusted by the Authority on account of seasonal conditions this adjusted annual use limit.

Managing drainage disposal

21 Where water use results in drainage from the land specified in the licence, that drainage water must be disposed in ways that meet the standards, terms and conditions adopted from time to time by the Authority.

Fees and charges

22 The licence holder must, when requested by the Authority, pay all fees, costs and other charges under the Water Act 1989 in respect of this licence.

1 Introduction

During the progressive rehabilitation works (culminating in the completion of the major earthworks in June 2020 and native grassland hydroseeding on the southern slopes in September 2020) the mine void water level (also referred to as the pit water level) has been slowly rising as forecast as a result of natural groundwater recovery and direct rainfall and local catchment runoff only, refer **Figure 1-1**. It is estimated that allowing the pit to naturally fill would take between 50 and 100 years.

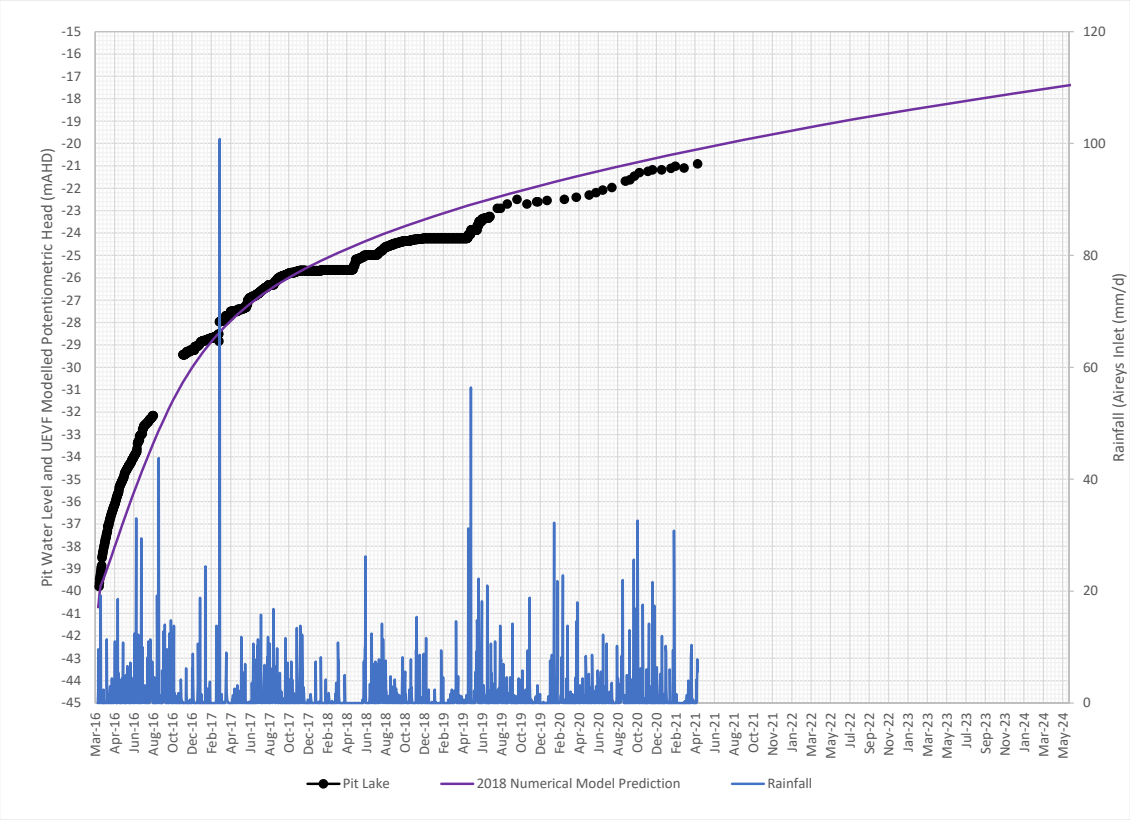

Figure 1-1: Actual and Predicted Natural Pit Water Level Recovery Over Time

Filling the mine void with water remains a key enabler for the draft Anglesea Mine Rehabilitation and Closure Plan (MRCP) as submitted to Earth Resources Regulator (ERR) in September 2017 (and the Eden Project Anglesea concept), with Alcoa's preferred "fast fill" strategy now based on a combination of surface water including potential peak flows from Salt Creek and groundwater sourced from the Upper Eastern View Formation (UEVF).

Whilst the use of surface water has not been agreed between Alcoa and the Department of Environment, Land, Water and Planning (DELWP), to enable further investigation of using groundwater and to commence the initial filling process, Alcoa proposes to undertake a 12-month groundwater pumping test of the Upper Eastern View Formation (UEVF) aquifer.

In September 2020, Alcoa submitted a Groundwater Impact Assessment (GIA) that looked at risks to the environment and other users if a 12-month groundwater pumping test of the UEVF aquifer was undertaken. On 26 October 2020, Alcoa received an amended groundwater licence from Southern

Rural Water (SRW) that permits the proposed 12-month groundwater pumping test and specifically the extraction of up to 1.5 GL of water '*for the purposes of discharging groundwater to the mine pit as part of the amended licence'*.

It should be noted that the proposed extraction rate is considered to be conservative compared to the long-term historical extraction of up to 4 GL per annum under Alcoa's existing UEVF groundwater licence during power station operation. The low extraction rate itself significantly mitigating any potential risks associated with the pumping test when compared to historical pumping.

A condition of the amended license was that *'An updated monitoring plan, including trigger levels and actions must be provided to SRW and accepted by SRW prior to any extraction occurring under this licence.*'

This monitoring plan is provided in response to that condition and as such also provides where necessary a summary of the GIA previously submitted.

1.1 Objectives of the Pumping Test

The overall objectives for the 12-month groundwater pumping test are to:

- Obtain additional hydrogeological data which can be used to develop a robust and peer reviewed numerical groundwater model that will determine if the use of longer term UEVF groundwater is a practical and environmentally sustainable water management strategy to fill the mine void as part of the MRCP (refer **Section 8**).
- Address data gaps identified in the draft MRCP (submitted to ERR September 2017 with a hydrogeological component update in 2018). These data gaps are summarised in **Section 1.7** of the original license amendment application referred to as the "Groundwater Impact Assessment".

To achieve this, it is proposed that the 12-month groundwater pumping test will be divided up into two periods each consisting of approximately six months, and is expected to;

1. within the first six (6) months:
    a. establish the required aquifer parameters;
    b. update the conceptual groundwater model; and
    c. Refine an existing numerical model (refer **Section 8**) that can be used to determine a sustainable extraction rate without unacceptable impact to other users or the broader environment.
2. After an approximate 2-week cessation period, groundwater extraction will then resume, and Period 2 will begin within the second six (6) months, and is expected to;
    a. complete model calibration and provide validation of the groundwater model and the associated risk assessment. This may involve Barwon Water pumping from the LEVF; and
    b. provide additional confidence to the community and key stakeholders.

The results will form part of a potential longer-term groundwater licence amendment application, with the aim that this will be submitted within the second 6-month period. The timing of the submission will be dependent on the results and ability of the numerical model to validate observed stress periods from the initial Period 1 trial.

As described above should the 12-month groundwater pumping test prove successful, Alcoa would prepare a further groundwater licence amendment to enable longer term use of the UEVF groundwater to support the mine void water body filling strategy (and also support the Eden

Project Anglesea concept) with this potentially being around 1.5 GL UEVF entitlement for up to 10 years. This would then be a key element in finalizing the submission of the Anglesea MRCP to ERR.

1.2 Objectives of the Monitoring Plan

The overall objectives for this monitoring plan are to:

- Provide the details of the groundwater monitoring network that will be used to monitor water level and water quality throughout the duration of the pumping test. This includes a rationale on bore locations.
- Provide a summary of environmental risks that the monitoring plan has been designed to protect or mitigate against potential impacts.
- To present a range of trigger levels for nominated trigger bores and contingency actions in the event a trigger level has been observed.

1.3 Take and Use Licence – BEE029662

On the 26 October 2020, SRW issued an amended groundwater licence including an Addendum (LH1575619) to the Take and Use Licence (BEE029662) and Licence to Operate Works (WLE0351661). These three documents are provided in **Appendix A**.

Outlined hereunder are the specific conditions in Addendum LH1575619;

1. *Alcoa's 4,000 ML Take and Use Licence BEE029662 has been amended to now include provision for the use 1,500 ML of the 4,000 ML to cater for what is effectively an eighteen (18) month pump test to facilitate the filling of the mine void at the now closed Anglesea Power Station and Coal Mine during this period and enable and establish the longer-term filling of this mine void.*
2. *The daily extraction rates from bores WRK041318 (WB16) and/or WRK041316 (WB14) combined is limited to 5.18ML/day (60 L/sec) and a total of 1,500 ML for the total duration of the 18-month licence.*
3. *An updated monitoring plan, including trigger levels and actions must be provided to SRW and accepted by SRW prior to any extraction occurring under this licence.*
4. *Monthly reporting must be provided to SRW of progress with the test and test results, including trigger levels and actions within four (4) weeks of the end of each calendar month.*
5. *The monthly monitoring report must include groundwater levels for bores P8/P12/P19 and reporting against Barwon Water's bulk entitlement trigger levels. In the event that these triggers are crossed while Alcoa is pumping then further analysis of the potential impacts must be undertaken by Alcoa and reported to SRW.*
6. *Confirmation is required prior to commencing extraction that the current Cultural Heritage Management Plan (CHMP) LH1575619 applies to both the area and the activity proposed.*

Note that the amended licence allows 18 months for completion of the proposed groundwater pumping test, allowing time prior to commencement for additional approvals (ERR), equipment set up, and completion of Item 3.

2 Background Information

The majority of the information presented in this section is provided for report flow and data familiarity and to give the reader some context related to the environmental conditions. This section has been summarised from the GIA submitted to SRW in September 2020 which led to the issuing of an amended groundwater licence to allow for a 12-month pumping test of the UEVF.

2.1 Hydrogeological Summary

A lithological summary of the main hydrostratigraphic units at the Site is provided in **Table 2-1**. The aquifer of focus for the pumping test investigation is the deeper zone of the UEVF (refer blue highlight in **Table 2-1**). A summary of this unit is provided in the following sections. **Figure 2-1** and **Figure 2-2** visualise the first 60 m beneath the broader site (former coal mine and power station).

Table 2-1 Lithological Summary

Hydrostratigraphic Unit	Unit	Elevation (mAHD)	Approx. Thickness (m)	Lithology
DBG	PWT Aquifer	+40 to +5	0 to 1	Topsoil
			2 to 20	Sandy clay.
	Boonah Sands Aquifer of the DBG	+20 to -10	1 to 25	Sequences of sands, clay, minor coal and silty clay
UEVF	Main Seam	-10 to -65	40 (25m of coal)	Coal
	Basal Clay	-15 to -70	1 to 4	Low permeability clay
	UEVF Upper Sands	-30 to -80	5 to 30	Sequences of coarse-grained sands and gravels interbedded with thin low permeability clay and coal
	L1 to L3 Seams and Interburden	-80 to -130	40 to 80	Thick sequences of low permeability coal, clay and thin sands
	Sub L3 Seam Sediments	-180 to -220	50 to 100	Low permeability coal and clay interbedded with discontinuous sand layers
	UEVF Basal Aquifer	**-230 to -280**	**30 to 60**	**Sands interbedded with silt, clay and thin coal**
MEVF	Aquitard	-285 to -355	40 to 70	Shale/mudstone
LEVF	Aquifer	-500	200 to 300	Sands interbedded with silt, clay and thin coal
Torquay Group	Basement	-500 +	>50	Bluey white sandstone

PWT – Perched Water Table
MEVF – Middle Eastern View Formation
LEVF – Lower Eastern View Formation

UEVF – Upper Eastern View Formation

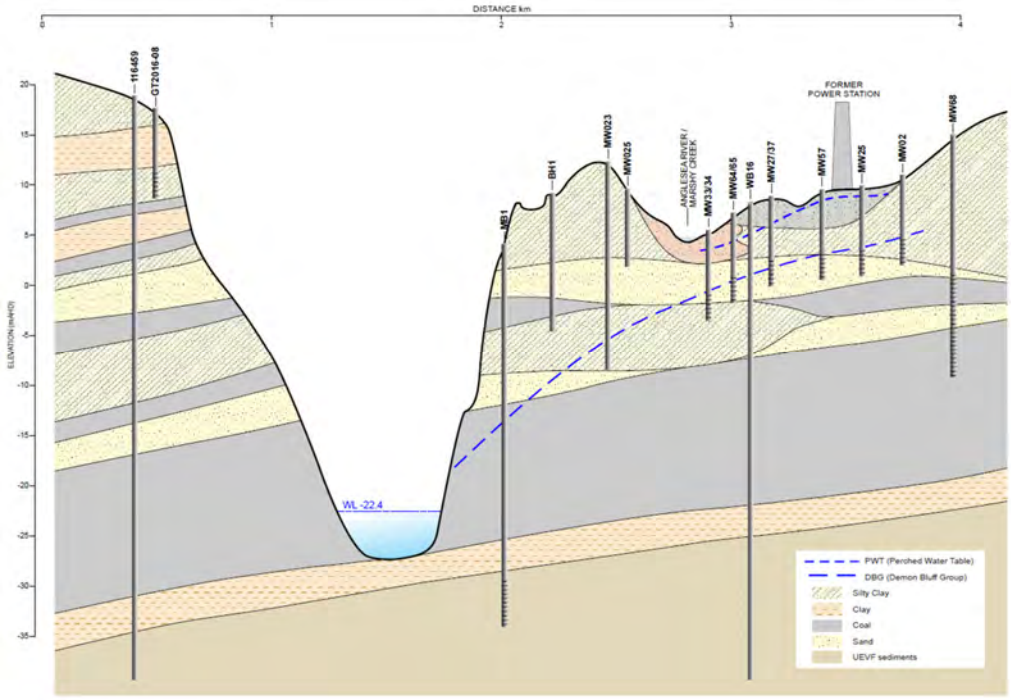

Figure 2-1: Mine Void CHM Cross-Section 1 (Water Levels from 2019)

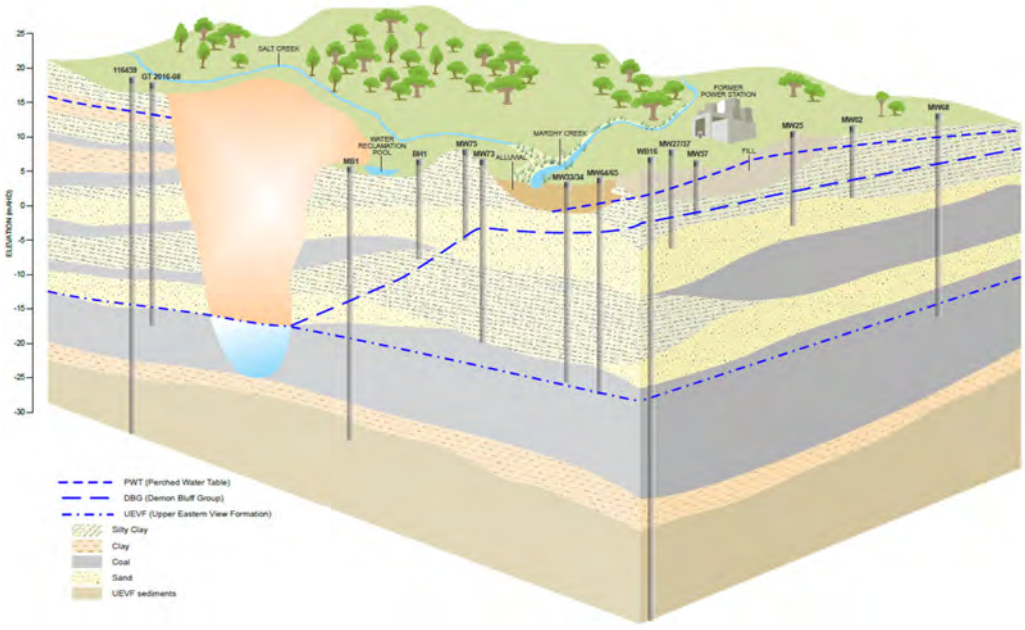

Figure 2-2: Mine Void CHM Cross-Section 2 (Water Levels from 2019)

2.1.1 Eastern View Formation

Hydrogeologically, the EVF can be sub-divided into three main units, namely the Lower, Middle and UEVF. In the vicinity of the coal mine, the upper unit is considered to be an unconfined to semi-confined aquifer, the middle unit an aquitard and the lower unit a confined aquifer. Broadly speaking, these water-bearing zones approximately represent the individual main aquifers within the EVF. However, sand aquifers occur at all levels in the sequence with potentiometric pressures increasing with depth, which means that multiple aquifers may exist within the one formation. **Figure 2-3** shows a cross-sectional relationship of each main formation from the ranges to the coast.

2.1.2 Upper Eastern View Formation

Generally, the UEVF forms an unconfined (where it outcrops) to confined aquifer and consists of clay, silty clay, silt and fine to medium-grained sand sequences with minor fine gravel lenses. A thick (20-30m) seam of brown coal is also common in the top of the UEVF sequence. In the vicinity of the coal mine, the UEVF is semi-confined, and approximately 200 to 250 m thick. Whilst the unit has been classified as a single aquifer, evidence of different potentiometric heads exists throughout the profile.

The 2020 drilling and wireline logging of 16 new bores and permeability testing of one new bore surrounding the coal mine (refer **Figure 4-3**) as well as wireline logging of the deeper production bores adjacent to the Power Station have also indicated that the UEVF can potentially be broken up into two more significant permeable units. Below the main coal seam and confining clay, a sequence of coarser sands ranging in thickness of 5-20 m is often identified, refer to **Photo 2-1** . This is referred to as the UEVF Upper Sands in **Table 2-1**. This upper sand is then separated by thick (100 m or more) of low permeability coal and clay (average permeability of $1x10^{-9}$ m/sec) before a lower section of coarser sands is found at the base of the UEVF. This is referred to as the UEVF basal aquifer in **Table 2-1**. These lower sands are where the former Alcoa production bores are screened and where the proposed pumping test bore (WB16) is screened, which is also located approximately 1.6 km from the mine pit void water body.

Photo 2-1 Photos of the UEVF Upper Sands from UEVF MB7

2.1.3 Middle Eastern View Formation

The MEVF is approximately 40 to 60 m thick and generally behaves as an aquitard by restricting vertical groundwater flow between the UEVF and LEVF. The MEVF generally consists of mudstone and siltstone, but also has minor sand and gravel lenses as well as thin brown coal layers. The unit generally appears to be continuous and consistent in thickness throughout the Anglesea area.

2.1.4 Lower Eastern View Formation

The LEVF forms a confined to semi-confined aquifer (in the upper parts of the catchment) across the region and consists of unconsolidated micaceous silts, carbonaceous clays, silty clays, thin brown coal seams and fine to coarse-grained sands and gravels. At the Site the LEVF is up to 200 m thick where aquifer material occurs within geological synclines. Groundwater total dissolved solids (TDS) in the LEVF is fresher than that observed in the UEVF.

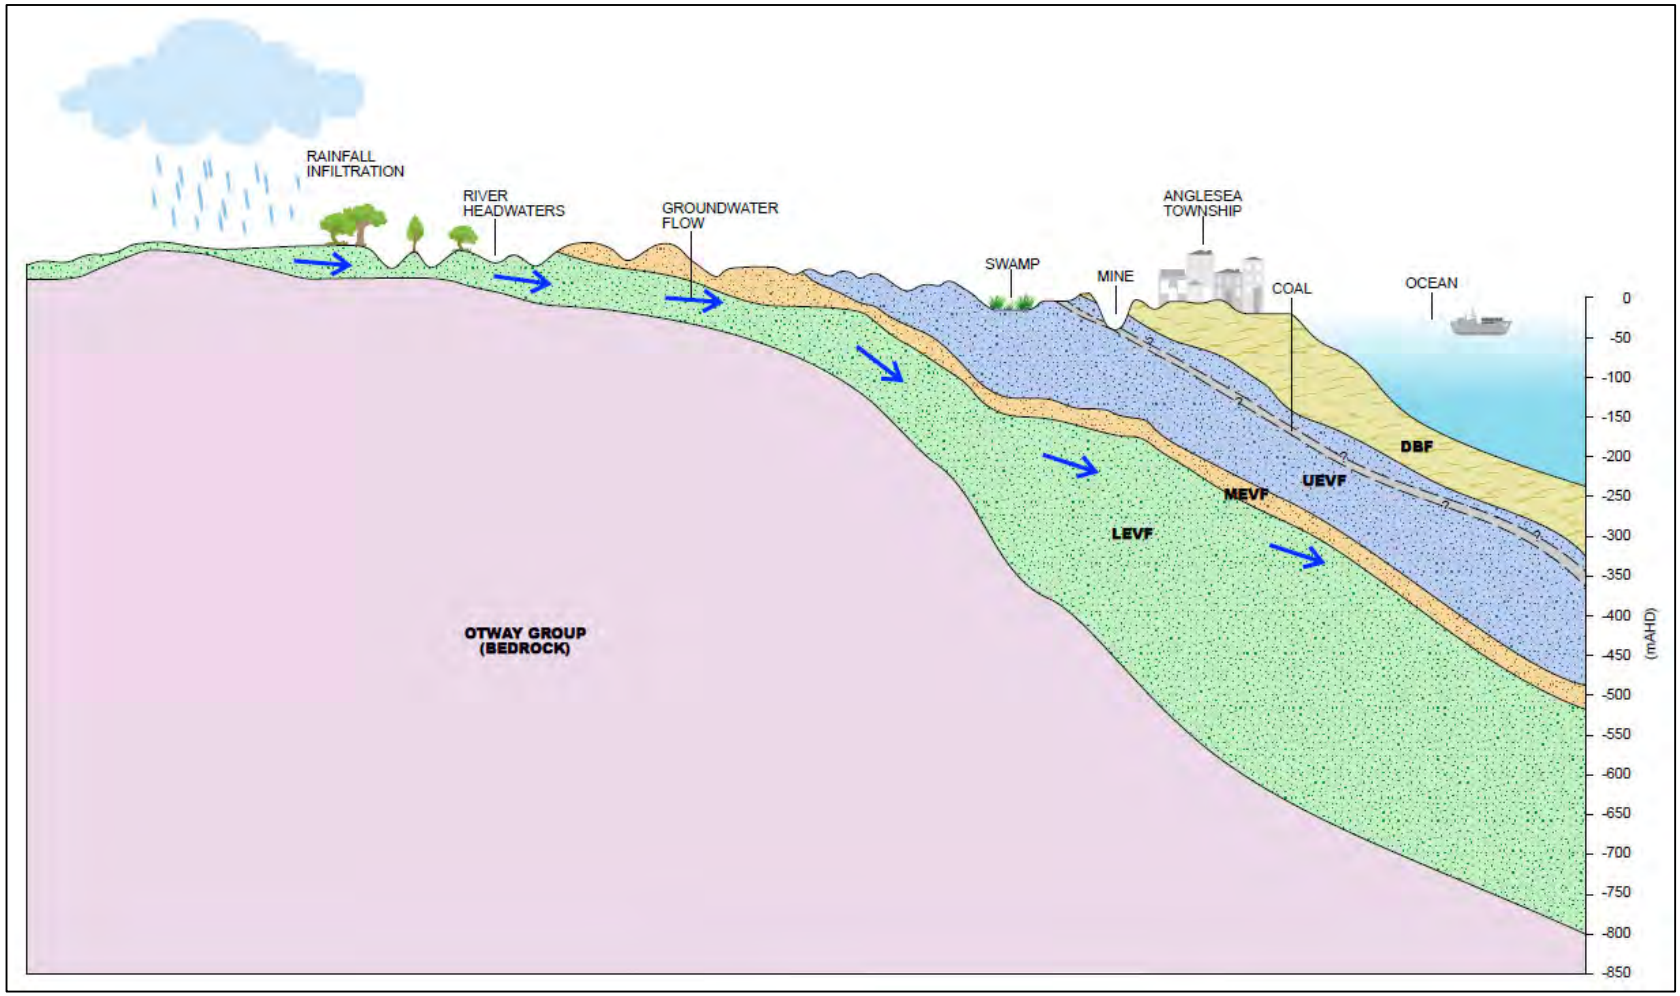

Figure 2-3 Regional Cross-Section (after GHD, 2013)

2.2 Groundwater Users

The location of the groundwater users (such as private and commercial water bores) are shown in **Figure 2-4**.

2.2.1 Private Bores

Groundwater bores within the local area have been determined through a search of the Victorian Water Measurement Information System (WMIS), refer **Figure 2-4**. The WMIS database was undertaken in October 2020 to identify registered bores within a 10 km buffer of the mine pit void and within the Jan Juc Groundwater Management Area (GMA).

A high density of stock, domestic and irrigation bores are located to the north-east of the Jan Juc GMA (north of Torquay); however, these bores are generally shallow and intersect the groundwater resources of the Beaumaris Sandstone (formerly known as the Moorabool Viaduct Sands) or the shallow sediments of the DBG. Of these bores, only two appear to be completed in the UEVF aquifer. Bore ID 68160 is completed to a depth of 278.9 m and located ~3 km south-east of the mine near the coast. Bore ID 68179 is completed to a depth of 28 m in coal and is ~8.5 km north-east of the mine.

The Moriac Quarry also has a licence to extract 250 ML/year. The quarry is located ~13 km north of the mine pit void with groundwater extracted from the LEVF (up-gradient of the Site) and used for industrial sand washing purposes.

Modelling simulations undertaken using conservative analytical solutions (i.e. Thies and Hantush-Jacob equations) predict no drawdown (Hantush-Jacob) and up to a maximum drawdown of 3.2 m (Thies) may be observed after 12 months of pumping at the nearest stock and domestic bore, 7 km from the pumping bore WB16. At the maximum drawdown case, this equates to a 1.4% loss of available drawdown assuming the licensed bore is screened within the UEVF. It is noted that predictions from the numerical groundwater model did not indicate any drawdown at this licensed stock and domestic bore. In fact numerical modelling suggests dewatering impacts resulting from the pumping test are likely to extend just under 3km, refer **Figure 3-2** to **Figure 3-5**.

2.2.2 Barwon Water Observation and Production Bores

Between 2007 and 2013, Barwon Water installed seven production bores (GW1 to GW7) in the LEVF and 42 observation bores in the LEVF, UEVF, DBG and PWT aquifers. These are shown in **Figure 4-2**.

2.3 Groundwater Dependant Ecosystems

Groundwater dependent ecosystems (GDE) as defined by the *Ministerial guidelines for groundwater licensing and the protection of high value groundwater dependent ecosystems 2015* means those ecosystems that require access to groundwater to meet all or some of their water requirements so as to maintain the communities of plants and animals and ecological processes they support and the ecosystem services they provide. This definition has also been used in the recent Anglesea River and Estuary Environmental Flow Study (GHD 2021).

Whilst there is always conjecture in determining the degree of groundwater reliance of certain GDE's (a process that often takes years and a high level of detailed studies to define), GHD 2021 present that within the Anglesea River Catchment there are some vegetated communities in the swamplands (defined as the Perched Water Table, PWT) that rely on less than 10% groundwater contribution and therefore meet the definition of a GDE. These swamplands are typically found in the mid and upper reaches of Salt Creek and Marshy Creek and are shown on **Figure 2-4**. Importantly no other GDEs or areas where they could exist were identified and GDE's were identified to be in direct connection to the UEVF. GHD 2021 also state that low permeability coal and clay underlying the PWT act as an aquitard separating the UEVF and the PWT. This is an observation that is supported by recent drilling and permeability testing, refer to **Section 4.3.1** with other multiple lines of evidence suggesting that the PWT is hydraulically disconnected from the UEVF. These are:

- Historical monitoring of DBG/PWT in the vicinity of the former Power Station show no changes in water level over time at historical pumping rates approximately 2.5 times that proposed for the 12-month pumping test.
- Extensive sequences of very low permeability coal, clay and silty clays separate the base of the PWT (and surface water features) to underlying aquifers, refer **Photo 2-2**. (These impermeable units are presumably the reason the PWT exist).
- Pre-development (Hancock, 1967) noted strong artesian conditions at the former Power Station from a bore screened in the UEVF at 138 mbgl. This indicates that the presence of clay layers between the surface and the water bearing zones of the UEVF are strongly confining.

3 Risk Assessment Overview

Two risk assessment processes were undertaken as part of determining the potential risks associated with the 12-month groundwater pumping test. These were:

1. A conventional risk assessment (e.g. consequence and likelihood) which was undertaken as part of the ERR Work Plan Notification process. This risk assessment aimed at identifying the risks that the activities may pose to the environment, to any member of the public, or to land or property in the vicinity of the activities.
2. A quantifiable risk assessment as part of the GIA which used a numerical model to quantify potential drawdown related impacts to overlying aquifers and surrounding beneficial users.

An overview of each "risk assessment" is provided below.

3.1 ERR Work Plan Risk Assessment

In December 2020 Alcoa submitted a risk assessment to ERR as part of the ERR Work Plan Notification – 12 Month Groundwater Pumping Test process, informing ERR of Alcoa's plan to undertake a 12-month pumping test with placement of the groundwater into the mine void. The risk assessment followed the process and definitions (e.g. likelihood and consequence ratings) as outlined in Version 6 Risk-based work plan using online RRAM - Guidelines for mining industry projects, issued by the Department of Economic Development, Jobs, Transport and Resources (DEDJTR).

This framework, along with risk assessment matrix's are attached in **Appendix B**. A summary of the risk assessment outcome is presented below.

With respect to water, the risk assessment identified as assessed the following risks (Elements):

1. Equipment failure resulting in groundwater to be discharged to surface water systems.
2. Pumping of groundwater resulting in a reduction of baseflow to surface water systems and potential GDE's.
3. Pumping of groundwater results in unacceptable impacts to stock and domestic bores and LEVF production bores.
4. Placing 1.5GL of water into the pit void adversely impacts surface water quality.
5. Placing 1.5GL of water into the pit void results in mine water migration into the UEVF.
6. Placing 1.5GL of water into the pit void results in the DBG and consolidated ash material to become saturated.
7. Equipment failure resulting in unplanned release of water causing erosion.
8. Equipment failure resulting in unplanned release of fuels or oil on to the ground.

Based on the consequence and likelihood classifications (noted above) and after adopting the appropriate control measures, all residual risks for the above are low. Of the above, items 2, 3 and 5 were addressed in the GIA with water level trigger levels for nominated trigger bores being adopted as a mitigation measure to ensure these risks remain low, refer **Section 6**.

3.2 Groundwater Impact Assessment

While it is considered unlikely that there are any GDEs in direct connection to the UEVF (i.e. the aquifer most likely impacted as a result from pumping - refer **Section 2.3**), and there are no other licenced users of groundwater within the targeted aquifer (i.e. UEVF), a numerical groundwater model was still developed to quantify the following potential impacts of the 12 month pumping test:

1. What is the drawdown in the UEVF and DBG as a result of the 12-month pumping test?
2. Will pit water recharge the underlying aquifer at the proposed extraction rate?
3. Will the proposed pumping test impact on environmental assets such as the Anglesea River estuary or unmapped GDE's?

The outputs of this impact assessment are presented in **Table 3-1** (note a positive number means the system is recovering). **Figure 3-2** to **Figure 3-5** present modelled drawdown in the lower sands (pumped section) of the UEVF after 3, 6, 9 and 12 months respectively at a pumping rate of 1.5Gl per annum.

The results indicate that leakage of pit water into the UEVF is not expected as there is no drawdown expected in the permeable zone of the UEVF located beneath the basal clay (UEVF upper sands) as well as the DBG and by association the PWT. Drawdown in the lower sands (where the pumping bore is screened) ranges from 45m at the pumping bore and roughly extending 2.5km before drawdown dissipates.

To validate these findings, state observation bore (SOB) 116459 screened in the lower sands of the UEVF located ~3km west of the pumping bore has exhibited a decline of 0.5m per year since 1998, refer **Figure 3-1**. This trend which may have been impacted by both Alcoa's historical pumping (which was previously undertaken at a rate more than 2.5 times what is proposed for this pumping test) as well as a significant decline in rainfall since the onset of the millennium drought, suggests that the modelled extent of drawdown is a reasonable estimate.

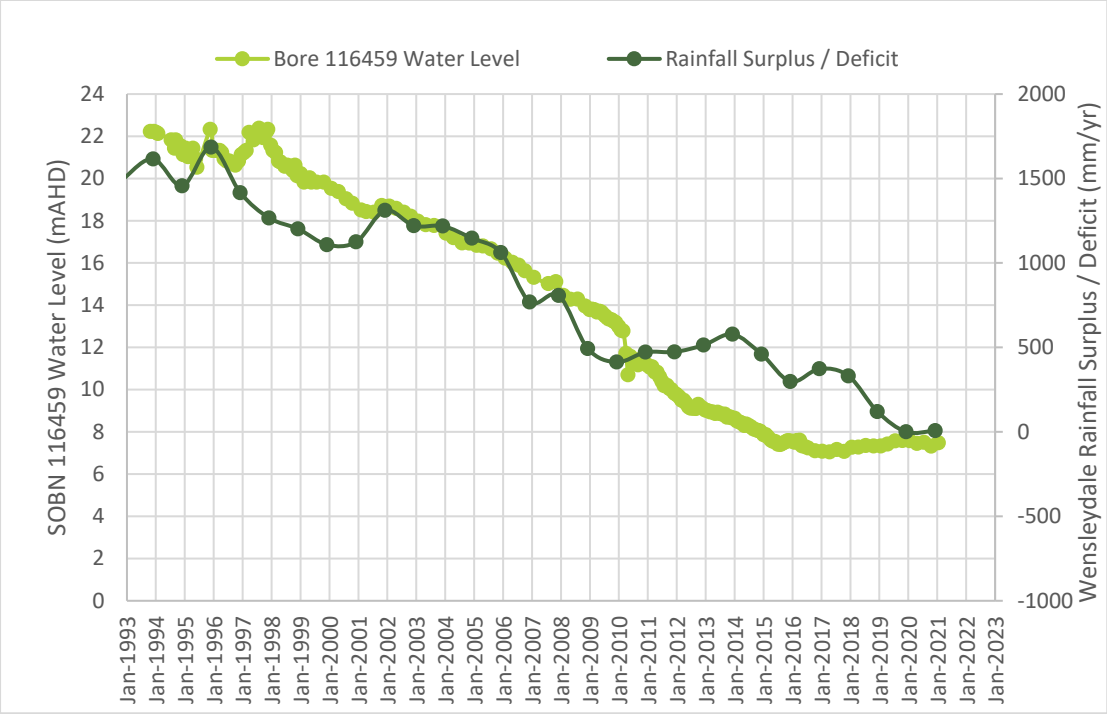

Figure 3-1 Historical Water Level in SOB 116459 and Wensleydale Rainfall Surplus/ Deficit

3.3 Summary of Risks to by Managed by this Monitoring Plan

As highlighted in the above sections, dewatering risks to GDE's and leakage from the mine pit into the underlying aquifer (the key risks to be mitigated) are expected to be negligible to low. However due to model and data uncertainty, risks associated with these assets will form a key part of the monitoring plan to ensure these risks remain low. As presented in **Section 6**, five (5) water level trigger rules are proposed with the rationale for each shown in **Table 3-2**.

Table 3-2 Water Level Trigger Rules

Trigger Rule	Method to Determine Trigger	Rationale (What Risk Does Rule Relate to)
Trigger Rule 1	Median monthly water level - 2 x Std Dev	Mitigate against dewatering impacts to GDE's connected to shallow aquifers (DBG/PWT).
Trigger Rule 2	Median monthly water level - 3 x Std Dev	
Trigger Rule 3	Historical low water level	
Trigger Rule 4	Predicted drawdown after 12 months	Mitigate against dewatering impacts of beneficial users where the UEVF outcrops.
Trigger Rule 5	If the level of Pit water level reaches - 15.5mAHD.	Manage the short-term risk of pit water migrating into the DBG and also reaching the level where historical ash was consolidated above RL -15m (north east corner of the mine) as an EPA licenced activity and covered with at least 1m of sandy clay overburden material. Note the water level is not expected to reach RL -15m during the 12-month pumping test.

It should be noted that as this is a pumping test, impacts resulting from stress testing the aquifer are required as this is the purpose of a pumping test. The aquifer needs to be sufficiently stressed (in this case de-watered) in order to obtain high quality parameters which can inform the development of a robust and fit for purpose longer term numerical model (the proposed One Model) discussed in **Section 8**.

4 Current Baseline Data

Note that with the exception of the mine pit water body, baseline surface water data will not form part of this monitoring plan. Whilst surface water data at gauging stations within the catchment is collected for other MCRP activities, it does not form a requirement for a pumping test monitoring plan.

4.1 Mine Pit Water Quality and Level

Surface water has been collected within the low point of the mine pit void and consists of rainwater runoff and groundwater recharge from the UEVF and the overlying DBG sediments.

Between July 1999 and April 2021, analysis of the mine pit void water has reported limited variability of the majority of analytes measured above the limit of reporting (LOR). TDS is observed to vary between 1,300 and 2,200 mg/L (refer **Figure 4-1**) and this appears to be influenced by increases in major ions particularly sulfate. These variations may be related to historical differences in water body location testing and/or the differing chemistry of groundwater and mine pit void runoff that contribute to the mine pit void water body. Although runoff is considered to comprise a small component of the water body volume, the sample location could be locally influenced by runoff to a greater extent than groundwater discharging to the water body.

The likely beneficial uses are therefore potentially limited to maintenance of freshwater ecosystems. However, exceedances of the maintenance of freshwater ecosystems (95th percentile) beneficial use are observed for magnesium, iron, aluminium, boron and copper (refer **Table 4-1),** (these guideline values are more conservative than the Australian Drinking Water Guidelines [ADWG] values).

It should be noted that natural background surface water quality in the area is characteristic of the low pH, elevated aluminium, boron and other trace metals reported within the mine pit void water body.

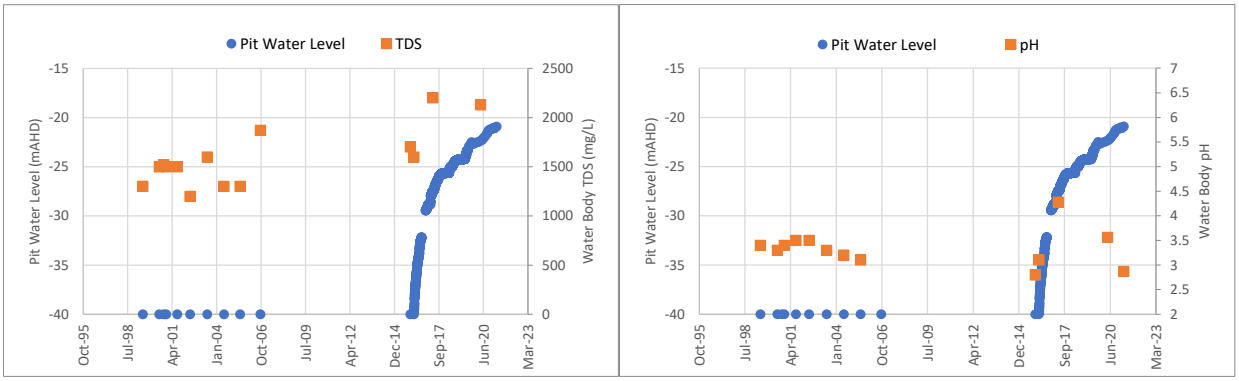

Figure 4-1 Mine Pit Water Level and Quality (TDS (Left), pH (Right)).

4.2 Catchment Wide Groundwater Monitoring Network

Within the catchment there exists over 130 dedicated groundwater monitoring bores belonging to either Alcoa (87 bores), Barwon Water (32 bores) and the State Government SOBN (14 bores). These bores are shown in **Figure 4-2**. Many of these bores have been installed for a variety of reasons. These reasons (i.e. their purpose) along with basic construction details is presented **Appendix C**.

4.3 Pumping Test Groundwater Monitoring Network

Of the 130 catchment wide monitoring bores, 28 have been selected to act as dedicated monitoring or nominated trigger bores for the pumping test. These bores are shown in **Figure 4-2** and their construction details in **Table 4-3**. All bores that have a measurable water level will have an automatic pressure transducer with data logger capabilities installed (recording on an hourly basis). Eight (8) bores have also been specifically nominated as trigger bores with specific mitigation actions defined in response to trigger levels being reached. These bores are discussed further in **Section 6**.

Inclusive of the bores discussed above are 16 newly constructed groundwater observation bores around the periphery of the mine. The location of these bores are shown in **Figure 4-3**. The rational for the construction depth and location of these bores is discussed in **Table 4-2** and **Table 4-3.**

Table 4-2 Rationale for Construction of New Near Mine Void Bores

Bore ID	Targeted Lithology	Rationale
UEVF MB 1	The upper sands of the UEVF, refer Table 2-1	The purpose for construction of these bores is to: • Obtain a greater understanding of the lithology and water levels in the upper section of the UEVF. • Confirm extensiveness of the basal clay which is assumed to overlie and confine theses “upper sands”. • To act as monitoring bores to monitor for potential drawdown impacts arising from the pumping test which could then imply drawdown from the mine pit waterbody into formation.

UEVF MB 4		
UEVF MB 5		
UEVF MB 6		
UEVF MB 7		
UEVF MB 8		
DBG MB 8	The permeable zones (Boonah Sands) in the DBG and located above the main coal, refer Table 2-1	The purpose for construction of these bores is to: • Obtain a greater understanding of the lithology and water levels in the DBG surrounding the mine. • To act as monitoring bores to monitor for potential drawdown impacts arising from the pumping test and to obtain baseline data which can be used to monitor for pit water / aquifer when the waterbody reached such level that pit water may naturally migrate into the DBG.

Table 4-3: Pumping Test Monitoring and Trigger Bores

Bore ID	Aquifer Monitored	Screen Interval (mbgs)	Trigger Bore (T) or Observation Bore (O)	Rationale
DBG MB1	DBG	37 – 40	O	These monitoring bores are located spatially around the periphery of the mine void located as close to practical and in a safe to access area. The monitoring objective of these bores are to confirm the presence and behaviours of any groundwater within the DBG. If during the 12-month pumping test the mine pit water level reaches -15mAHD (currently water level is at -21mAHD), the pit water has the potential to migrate into the DBG formation. This was subject of EHS Support 'Ash Assessment Study' for the draft MRCP Appendix K as submitted to ERR Sept 2017 which indicated that geochemical mixing and transport modelling indicated that the discharge of ash pore water into UEVF groundwater or pit water body is likely to have a negligible effect on receiving water chemistry and also indicted that it would take up to 159 years for a particle of water to migrate into the formation. On this basis the risk of any adverse impact on groundwater was risk assessed as low risk. If this however does eventuate, data from these bores will be used with analytical and predictive modelling to estimate the seepage velocity from the pit back into the formation.
DBG MB2	DBG	60 – 63	O	
DBG MB3	DBG	69 - 72	O	
DBG MB4	DBG	35 – 38	O	
DBG MB5	DBG	18 – 21	O	
DBG MB6	DBG	34 – 37	O	
DBG MB7	DBG	8 – 11	O	
*DBG MB8	DBG		O	
MW27	PWT/DBG	10 -15	O	These bores are located in close vicinity (<250m) around the pumping bore and screened in either the shallow DGB formation or PWT associated with the surface water systems. These bores are also located as far away as practical from former power station assets such as the water reclamation pond which may influence water levels. MW27, MW 33 and MW29 are also located adjacent to Marshy Creek. Monitoring of these bores will be undertaken to understand potential surface water / groundwater interactions. Past monitoring of these bores suggest that there also exist sufficient water column to obtain water quality samples and are unlikely impacted by past mine activities.
MW29	PWT/DBG	6-12	O	
MW33	PWT/DBG	8 – 14	T	
MW37	PWT/DBG	3 – 6	O	
MW64	PWT/DBG	7 – 13	T	
UEVF MB1	$UEVF_U$	92 – 98	O	These monitoring bores are located spatially around the periphery of the mine void located as close to practical and in a safe to access area. The monitoring objective of these bores are to monitor for potential drawdown caused by pumping. If drawdown does occur in these bores, it increases the potential for mine water to seep into the aquifer which should be
UEVF MB2	$UEVF_U$	122 – 128	O	
UEVF MB3	$UEVF_U$	139.3 - 145.3	T	

Bore ID	Aquifer Monitored	Screen Interval (mbgs)	Trigger Bore (T) or Observation Bore (O)	Rationale
UEVF MB4	$UEVF_U$	71 – 77	O	minimised where possible. These bores will also help understand how different permeable zones in the UEVF behave which can then be used to help calibrate a numerical model.
UEVF MB5	$UEVF_U$	59 – 65	T	
UEVF MB6	$UEVF_U$	69 – 75	O	
UEVF MB7	$UEVF_U$	42 – 51.6	T	
*UEVF MB8	$UEVF_U$		T	
WB4	$UEVF_L$	108.2 – 195	O	These bores are either former power station production or observation bores. They are screened in the lower part of the UEVF and will monitor drawdown as a result of pumping. The data will be used to provide reliable hydraulic parameters for a future numerical model. Note: the lower 2 screened section of WB15 have been identified as potentially in the MEVF and as such to be conservative a packer will likely be installed in this bore to seal off these screened sections from the UEVF. Drawdown observations within these bores will also be used to ensure drawdown does not exceed what was modelled in the GIA and thus potential risks to environmental assets in outcrop areas remain low.
WB5	$UEVF_L$	132 – 216.6	T	
WB12	$UEVF_L$	147.2 – 221.3	O	
WB14	$UEVF_L$	155.9 - 213.7	O	
WB15	$UEVF_L$	186.8 - 247.5	O	
WB16	$UEVF_L$	173.7 – 220.2	PB	This is the Pumping Bore.
116459	$UEVF_L$	243 - 246	T	This is a state observation bore with a long history of water level data. Drawdown observations within this bore will be used to ensure drawdown does not exceed what was modelled in the GIA and thus potential risks to environmental assets in outcrop areas remain low.

$UEVF_U$ = Upper Sands of the UEVF
$UEVF_L$ = Lower Sands of the UEVF
*Currently being constructed

4.3.1 Learnings from Installation of New Observation Bores

As shown in **Figure 4-3,** 8 nested pairs of bores have been installed in to the shallow DBG and the upper sands of the UEVF around the periphery of the mine. Geological core has been retained from several bores (UEVF MB 7, UEVF MB 3 and UEVF MB 8) and 5 core sections within UEVF MB 7 were subject to laboratory permeability tests. Key learnings with respect to the overall conceptual hydrogeology are summarised below.

- The majority of the DBG bores are dry indicating that near the mine void, these units discharge water into the mine void.
- The upper sands is not present at UEVF MB8 indicating that these sands may be discontinuous.
- The basal clay has been identified in all UEVF bores ranging in thickness of 1 to 5m with the exception of UEVF MB 6. At this location its thought that the mining of coal may have also scraped the basal clay to a minimal thickness.
- Field water quality parameters are variable with TDS ranging from 194 to 3919 mg/L, refer **Table 4-4**.
- Laboratory permeability tests of clay and coal sections within UEVF MB 7 indicate that permeability ranges from 7E-10 m/sec at 33mbgl to 3E-9m/sec at 55mbgl to 2E-9m/sec at 70.5mbgl and 1E-10 m/sec at 140mbgl.
- A total cumulative thickness of over 100m of low permeability clay and coal sequences separate the upper sands and lower sands of the UEVF suggesting that there is a very low risk of dewatering impacts being observed in the UEVF upper sands or overlying formations. This also means that it is likely that in the lower section of the UEVF, dewatering impacts may extend further due to the lower transmissivity (i.e. smaller thickness of formation), however this is not observed at SOB 116459, refer **Section 3.2** and **Figure 3-1**.

Table 4-4 Water Quality Results (Field Parameters from a GME undertaken April 8-12, 2021)

4.4 Baseline Data – Groundwater Levels

4.4.1 DBG/PWT Aquifer - Alcoa Entire Bore Network

Shallow groundwater levels have been recorded at the Anglesea Power Station since February 1993; with the results from 2006 – 2020 presented in **Figure 4-4**. Of the bores shown, MW33 is located nearest to the Anglesea River/Marshy Creek and furthest from surface water management assets associated within the Power Station (i.e. former Ash Ponds). This bore shows a water level of approximately -4.2 mAHD, some 9 m deeper than the base of the Creek, indicating that the Creek is not dependant on groundwater.

Prior to Alcoa development, groundwater levels in the shallow unconfined aquifer were estimated to be around -4 to +4 m AHD (Hancock, 1967). Data from piezometers in the mine south wall holes are plotted in **Figure 4-5**, and show that, after an initial stabilising period, groundwater levels fall within historical reported levels. However, before being decommissioned, VWP2S was still trending upwards. Furthermore, VWP1S shows a response of almost 1 m after heavy rainfall in March 2017 indicating potential unconfined conditions.

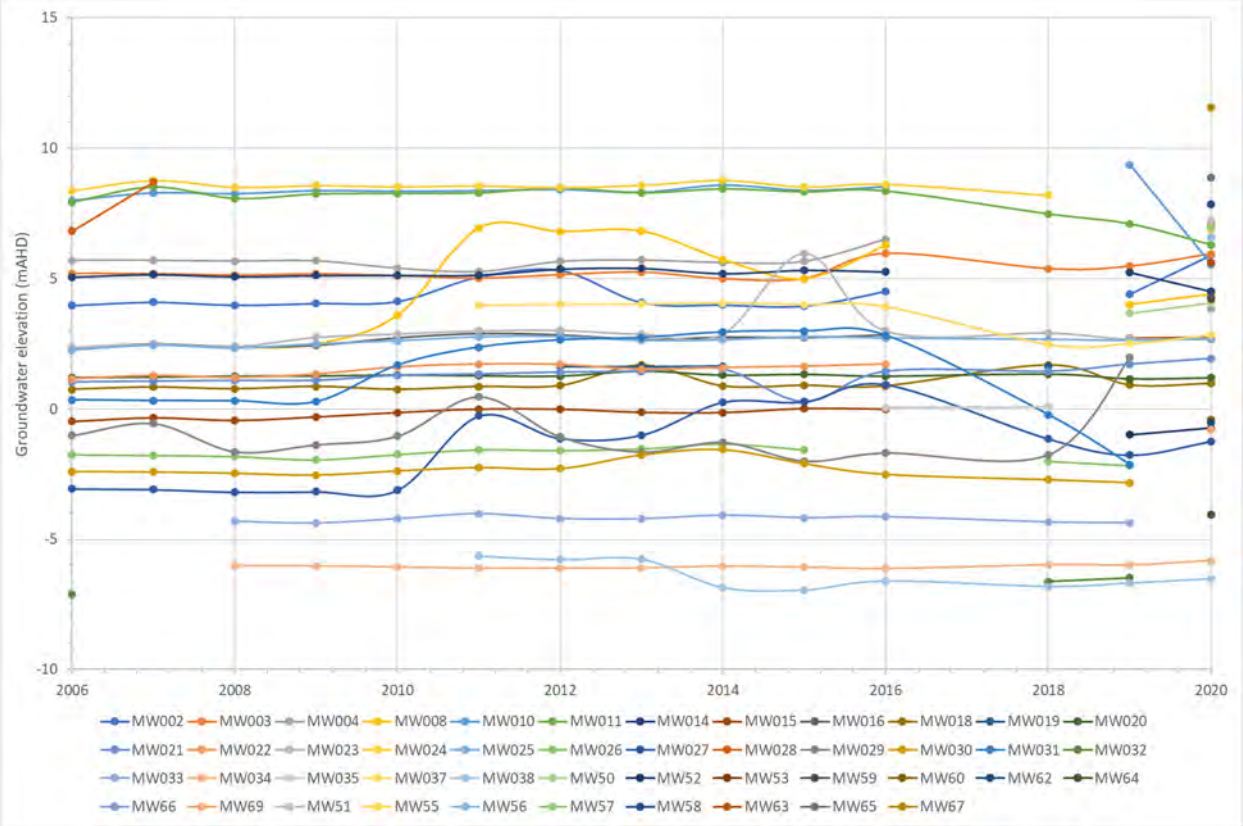

Figure 4-4 All Alcoa Power Station DBG/PWT Bores – Long-term Groundwater Levels

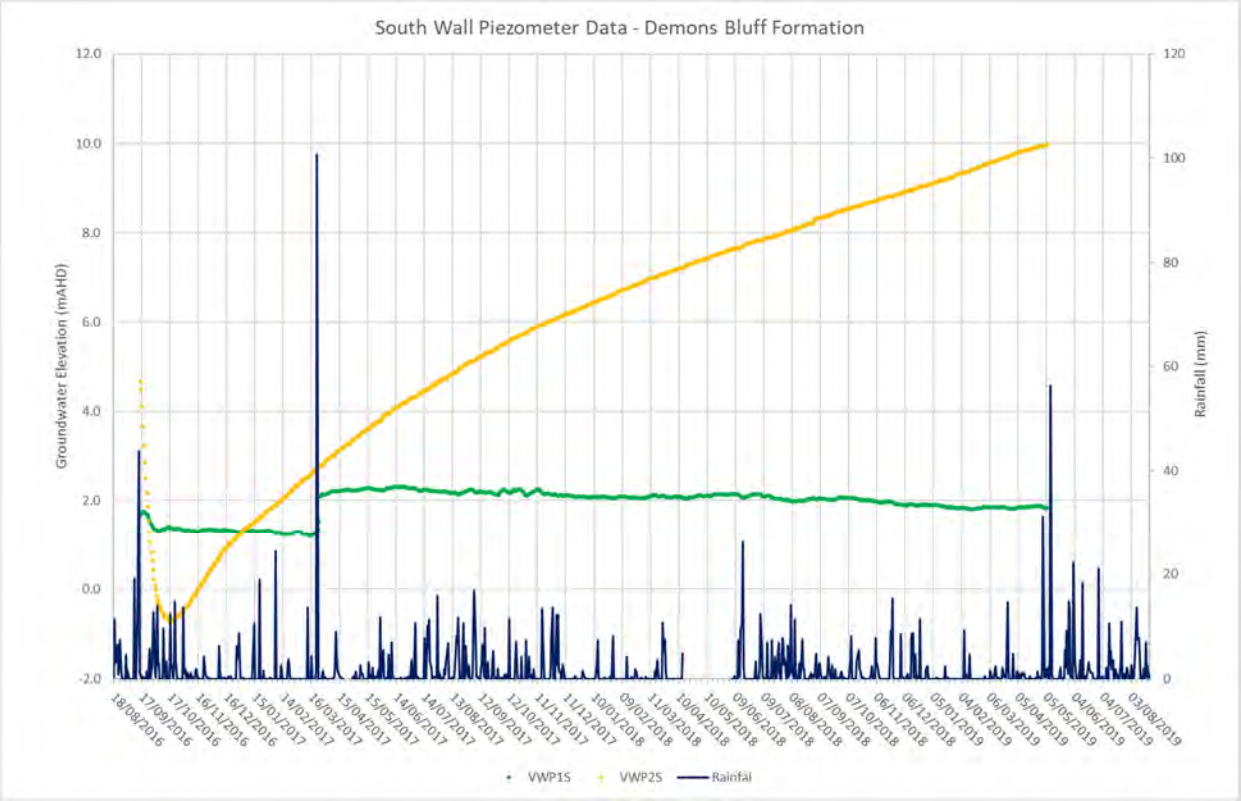

Figure 4-5 South Wall Piezometer Data, DBG (Rainfall obtained from Aireys Inlet, BOM ID: 090180, 6 km south-west of Site)

The PWT aquifer is a discontinuous perched unit associated with the upper weathered and disturbed zones of the DBG, as well as the alluvial channel fill deposits adjacent to Salt Creek and the Anglesea River outside of the Site. The PWT aquifer follows topography flowing in a south-west direction from the former Power Station Site. Groundwater elevation ranges from approximately 8.2 mAHD at MW67 in the north-west corner of the former Power Station to 2.5 mAHD at MW37 along the stormwater drain. Recharge to the PWT aquifer mostly occurs through stream/river loss.

4.4.2 DBG/PWT Aquifer - Nominated Monitoring Bores

For those monitoring bores screened in the DBG and PWT, the objective is to mitigate against water level impacts of surficial environmental receptors. Groundwater elevations of these monitoring bores are shown on **Figure 4-6**.

Note: as shown in **Table 4-4** the majority of the newly installed DBG bores around the mine are dry.

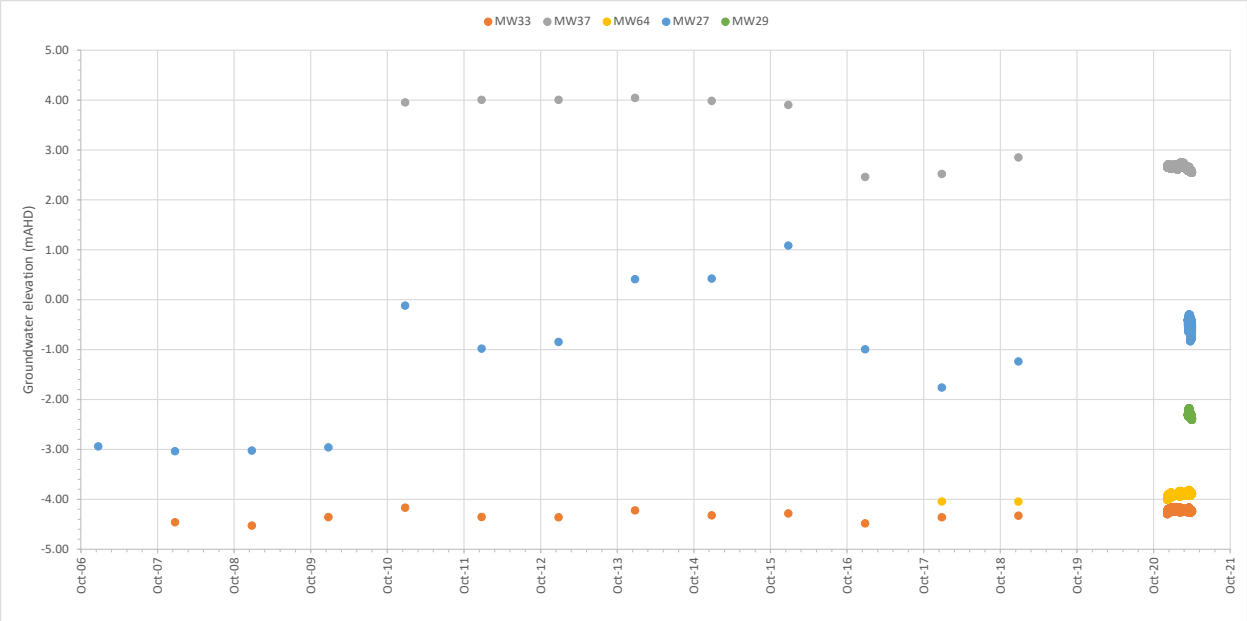

Figure 4-6 DBG/PWT Monitoring Bores – Historical Groundwater Level

It should be noted that the pumping test will place up to 1.5 GL of water into the mine pit void. The current mine pit void water level is approximately-21mAHD. Without the addition of this water, after 12 months, the water level is anticipated to rise to approximately -20.3 mAHD. With the additional 1.5 GL, the water level is expected to rise to approximately -17 mAHD. At the Site, the DBG begins above the main coal seam, the base of which is found approximately -15.5 mAHD. As such, there is not expected to be any interaction between the mine pit void water body and the DBG groundwater.

4.4.3 Deeper Zone of UEVF Aquifer - Nominated Monitoring Bores

The bores screened within the deeper zone of the UEVF surrounding the pumping bore (WB16) that have been nominated as monitoring bores include WB4, WB5, WB12, WB14 and WB15. Historical longer term groundwater monitoring data was available for WB4, WB5 and WB12 only (**Figure 4-7**).

Figure 4-7 presents all monitoring bore water level data in the UEVF with these bores screened in the deeper portions of the UEVF. These bores are screened closer to (both spatially and vertically) the pumping bore and as such have been impacted by Alcoa's UEVF pumping. However, since pumping has ceased, groundwater is recovering at a faster rate than those screened in the upper zone of the UEVF, highlighting the disconnect between the upper and lower zones.

Figure 4-8 presents recent water level data logger data since the installation of these automatic dataloggers in the nominated monitoring bores. The small drawdown observed on the 29/03/2021 is associated with installation and commissioning of the pump for the groundwater test within WB16.

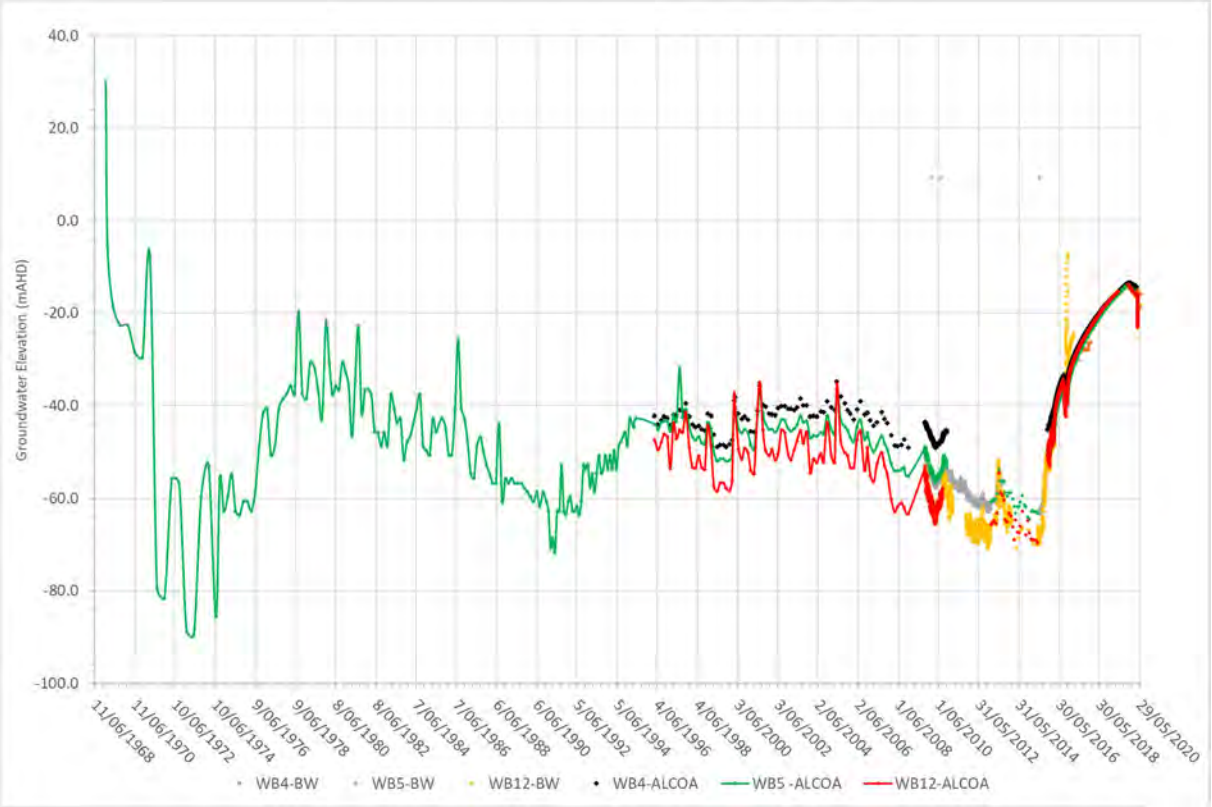

Figure 4-7 Deep Zone of UEVF Aquifer Monitoring Bores – Long-term Groundwater Levels

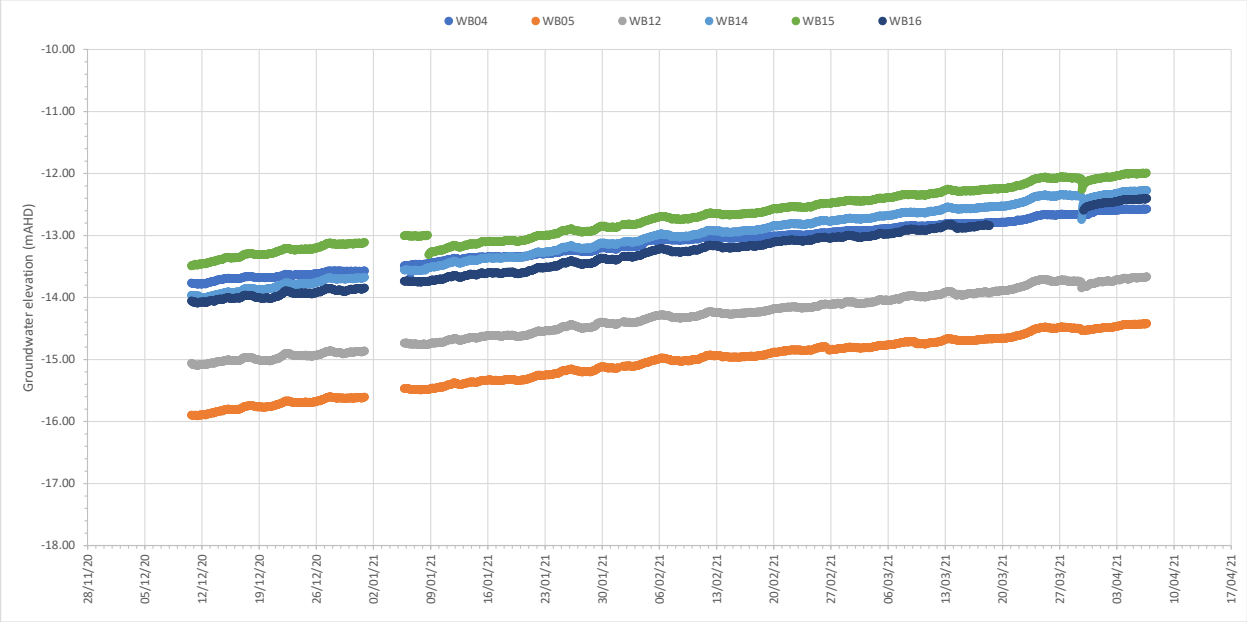

Figure 4-8 Deep Zone of UEVF Aquifer Monitoring Bores – Recent Groundwater Levels

4.4.4 Upper Zone of the UEVF Aquifer - Nominated Monitoring Bores

As noted above, 8 additional groundwater monitoring bores were installed surrounding the mine pit void and screened in the upper zone of the UEVF aquifer (UEVF MB1 to UEVF MB8). The purpose of these bores is to monitor any potential drawdown impacts associated with the 12-month pumping test and/or seepage from the mine pit void during the 12-month pumping test.

Seven of the eight bores have now been installed (as of 15 April 2021), with UEVF MB08 proposed to be completed by the end of April 2021. As a result, a long-term groundwater level database is not available to assist with defining a baseline groundwater level. Dataloggers have been deployed and those with more than 1 month of data are shown in **Figure 4-9**.

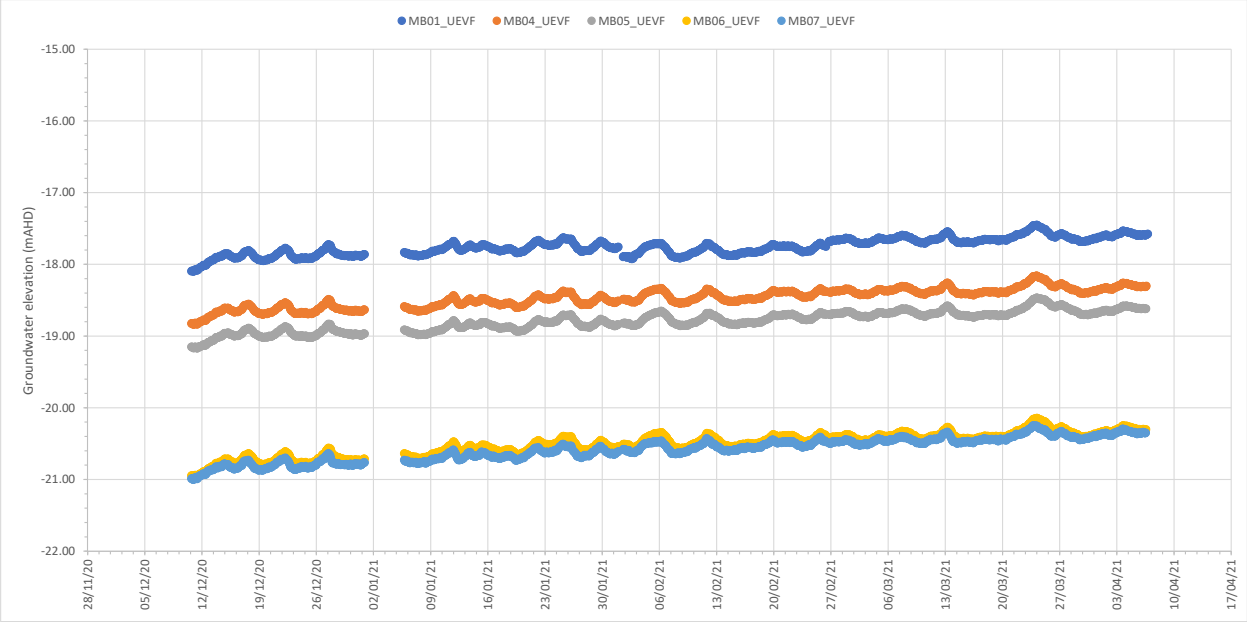

Figure 4-9 Shallow Zone of UEVF Aquifer Monitoring Bores – Recent Groundwater Levels

4.4.5 Barwon Water Trigger Bores

A condition on the Alcoa Licence Amendment (**Appendix A**) is that monthly monitoring of three Barwon Water bores P8, P12 and P19, which form part of Barwon Water's bulk entitlement monitoring program, must be undertaken.

Barwon Water have confirmed that monitoring bore P8 is screened in the PWT, P12 is screened in the LEVF and P19 is screened in the UEVF. Barwon Water have also confirmed that trigger levels have only been developed for P8 and P19 only, using the background/compliance bore, P17, to correct for natural climatic variation. The control bore is located in the Salt Creek swampland which is deemed outside the area of influence from pumping of the Barwon Water Anglesea Borefield. This means the control bore provides a useful comparison of the natural variation in groundwater levels due to seasonal conditions.

P12 is only being monitored to assess any potential drawdown impacts to the LEVF, which is considered unlikely given that vertical hydraulic gradients are already upwards.

Historical groundwater level fluctuations from these bores are shown on **Figure 4-10**. It is noted that Barwon Water will collect daily groundwater levels from these four bores during the 12-month pumping test.

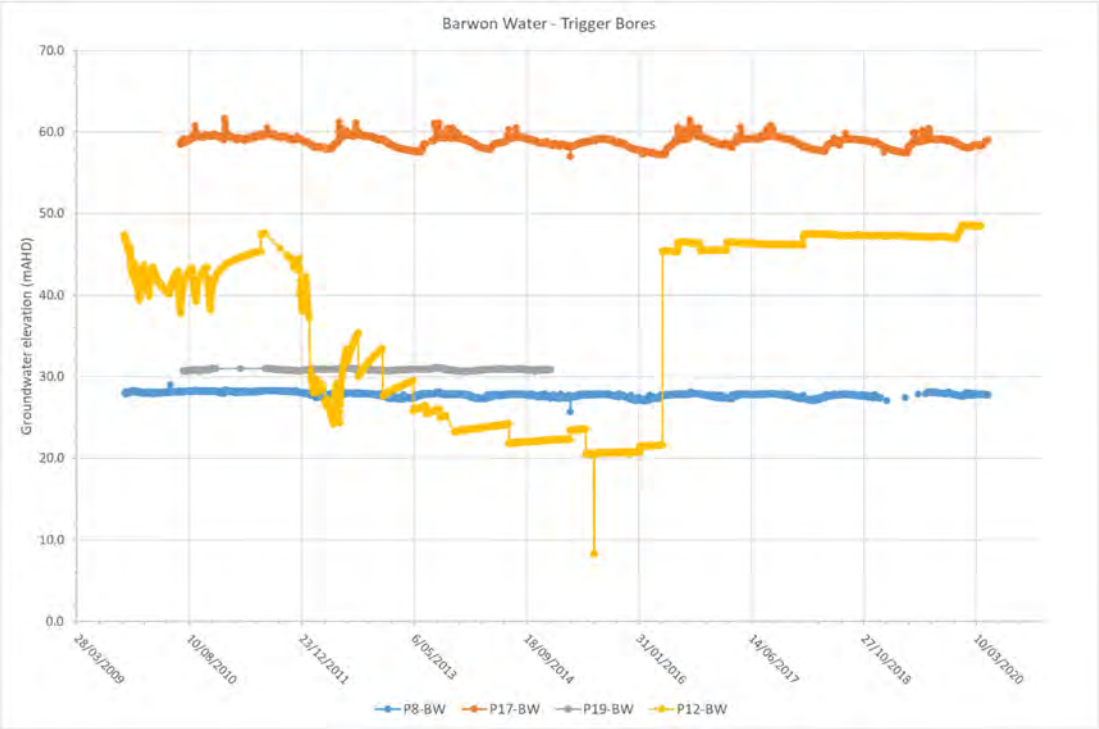

Figure 4-10 Barwon Water Trigger Bores – Historical Groundwater Level Data

4.5 Baseline Data – Groundwater Quality

4.5.1 DBG/PWT Aquifer

Historical TDS data for the selected monitoring bores in the DBG/PWT aquifer are presented in **Figure 4-11**. Considerable variability is noted and this is consistent with observations across the broader catchment. For a detailed overview of broader water quality refer Alcoa / Coffey annual GME reports 2006 to 2020, however in summary the following is noted concerning dissolved phase metals in the DBG/PWT aquifer:

- Antimony, beryllium, cadmium, total chromium, mercury, molybdenum, selenium, tin and vanadium have not been detected in concentrations exceeding relevant screening criteria.
- Aluminium, barium, cobalt, copper, iron, manganese, nickel, zinc and lead exceeded relevant screening criteria; however, the concentrations detected on Site are similar to or less than upgradient background well MW067. Therefore, it is likely that the elevated concentrations are representative of background concentrations.

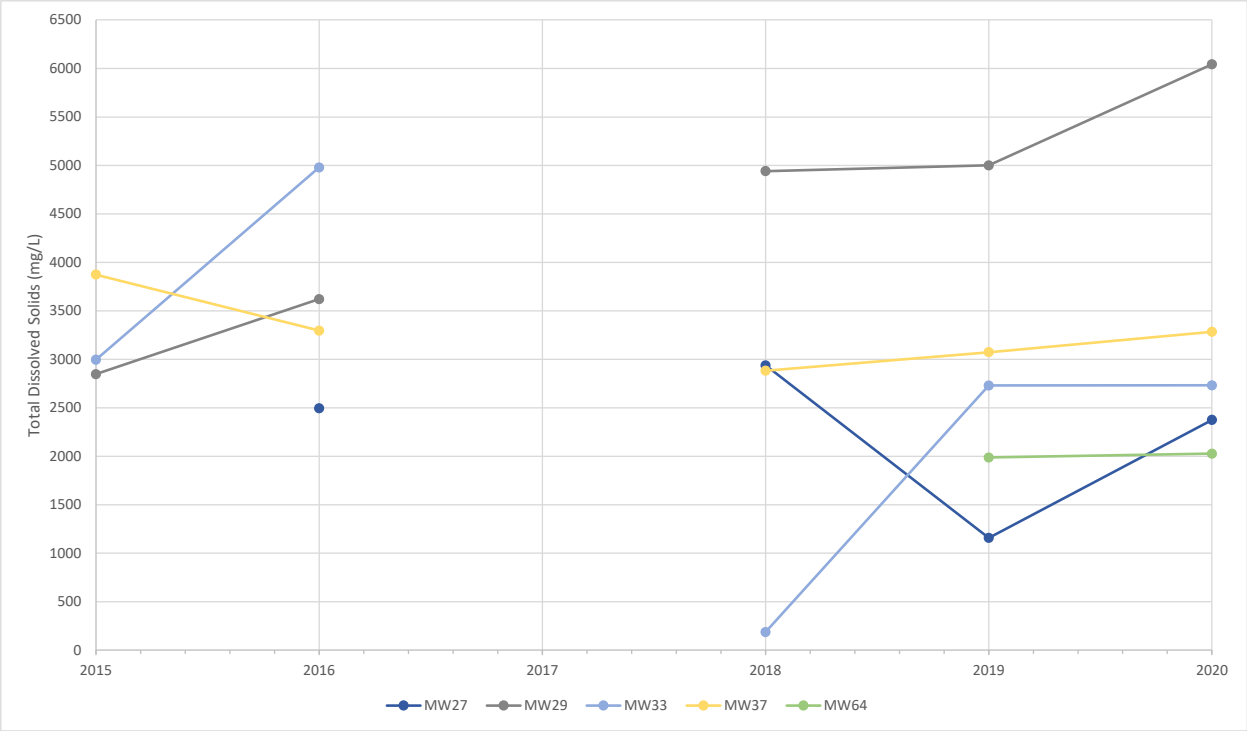

Figure 4-11 Historical TDS Measurements – Alcoa Mine Site DBG/PWT Bores

4.5.2 UEVF Aquifer

Only sporadic historical pH data from the groundwater monitoring bores screened in the deeper zone of the UEVF is available. This is presented in **Figure 4-12** and summarised in **Table 4-5.** Furthermore, **Figure 4-12** shows TDS from the bores located across the Power Station Site screened in the deeper zone of the UEVF ranged from 692 to 1300 mg/L. Individual bore statistics for TDS are summarised in **Table 4-6**.

5 Pumping Test Description

5.1 Methodology and Design

The objectives of the 12-month groundwater pumping test are provided in **Section 1.1**. The principle of a pumping test involves applying a stress to an aquifer by extracting groundwater from a bore and measuring the aquifer response to that stress by measuring drawdown as a function of time. The measurements are incorporated into an appropriate well-flow equation to calculate the hydraulic parameters of the aquifer.

5.1.1 Aquifer Testing Program

A draft outline of the proposed stages of the aquifer testing program are presented in **Table 5-1**.

Table 5-1 Aquifer Testing Program

Stage	Activity	Date
Stage 1	Complete installation of groundwater monitoring bores around the mine pit void	End of April 2021
Stage 2	Datalogger installation and baseline monitoring period	Dataloggers installed by end of April 2021.
Stage 3	Begin Period 1 constant rate test (~50 L/sec)	May 2021
Stage 4	End Period 1	November 2021
Stage 5	2-week recovery period	November 2021
Stage 6	Start Period 2	November 2021
Stage 7	End Period 2*	June 2022*

*It is noted that the amended license allows 18 months to complete the pump test from 26 October 2020, with an end date of 26 April 2022. If any extension is required based on the above nominal timeline, then this will be discussed in advance with SRW.

5.1.2 Pumping Bore – WB16

WB16 is the nominated pumping bore and is shown in **Photo 5-1** and **Photo 5-2**. If for some reason WB16 becomes compromised WB14 and/or WB15 will be further evaluated for use as the pumping bore. This may involve undertaking step drawdown tests to establish the bore efficiency.

The construction details of the pumping bore WB16 are summarised in **Table 5-2** and the bore log is presented in **Appendix C**. The pumping bore has multiple screened intervals that all intersect the deeper zone of the UEVF. The bottom of the pumping bore is understood to be located at the base of the UEVF (i.e. where it intersects the MEVF).

220.2	226.4	203	Fibre glass reinforced plastic casing

Table Notes:
mbgl – metres below ground level
mm - millimetres

5.1.3 Proposed Extraction Rate and Discharge

It is anticipated that a proposed extraction rate of 50 L/sec (±10 L/sec) will be adopted for the during of the 12 months, with the total extraction not to exceed 1.5GL. This extraction rate is approximately 40% of the annual historical extraction (between 1998 to 2015). Discharge monitoring will be undertaken via a dedicated magnetic flow meter at the pumping bore (refer **Photo 5-2**).

The pumped water will be transferred via pipe (connected at the wellhead, refer **Photo 5-1**) to the mine pit void where it will be discharged below the current mine water level, refer **Photo 5-3** and **Photo 5-4**. This will mitigate contact to atmospheric oxygen as well as potential erosion.

Photo 5-3 Discharge Pipe

Photo 5-4 Discharge Location

5.1.4 Pumping Test Evaluation

During the test and following the completion of Period 1 (i.e. 6 months of pumping) reviews will be conducted on the validity and appropriateness of the adopted groundwater monitoring bore network and monitoring and sampling program. This may include removing or adding bores to the network and/or increasing or reducing the frequency of monitoring and sampling. Further details on the monitoring and sampling plan are provided in **Chapter 7**.

5.1.5 Proposed Technical Steering/Reference Committee

A Co-Regulators Forum and Technical Working Group has been established as proposed by Alcoa to provide a forum for engagement and consultation with Alcoa and regulatory agencies about statutory, regulatory, and technical issues and activities related to the rehabilitation and closure of the Anglesea Coal Mine. This will be facilitated by ERR and specifically includes oversight of the 12-month groundwater pumping test, and comprises representatives from;

- Earth Resources Regulator (ERR)
- EPA Victoria (EPA)
- Department of Environment, Land, Water & Planning (DELWP)
- Southern Rural Water (SRW)

- Barwon Water and Corangamite Catchment Management Authority (CCMA) participation to be determined by ERR
- Independent Peer Reviewer (to be agreed)

as the appropriate regulatory and/or referral agencies to convene on a monthly basis to provide progress reports and technical updates throughout the 12-month groundwater pumping test.

The intent is to ensure there is common information/data being shared and discussed as required by all groups and for this forum to provide further opportunity for questions, concerns or risks to be raised and addressed as they arise, inclusive of review of any trigger value exceedances and proposed action plans.

6 Trigger Values and Response Actions

6.1 Trigger Level Methodology

Trigger values and response actions are developed to proactively respond to observed changes in the environment as a result of pumping activities and to both mitigate potential risks and also meet compliance objectives. While assessments have been conducted, inherent uncertainties must be addressed through monitoring. Given that the monitoring and management program is dynamic, assessments of performance of management activities need to be conducted over time and modifications made as required. In the context of this type of monitoring and management framework, a well-defined set of response actions for nominated trigger bores provides for protection of the environment, allows for proactive management of water quality issues and ensures regulatory compliance.

The groundwater framework for response actions is focused on groundwater levels (pressures) and water quality, with the any potential changes in water quality due to recharging the aquifer from the mine pit void water body the primary risk driver.

The response plans will involve six fundamental actions in relation to groundwater levels and groundwater quality. These are:

1. Preliminary analysis of data using summary statistics and trend analysis to assess whether data is consistent with historical monitoring and/or baseline data. This analysis will primarily involve the use of median water level across a defined period, standard deviations (Std Dev) of the same period and historical minimum. The methodology is further described in **Section 6.1.1**.
2. Decisions to re-gauge or re-sample (and analyse) the location, increase monitoring frequency or continue monitoring at the location.
3. Evaluate groundwater level change in relation to other surrounding monitoring bores.
4. Detailed assessments of geochemistry and key monitoring parameters at the monitoring locations.
5. Root cause analysis (for example climatic variation) of the likely source of variability (natural or induced by other activities).
6. Develop and implement an appropriate contingency plan in discussion with SRW or the monthly TRG meeting.

Note that for nominated trigger bores specific defined actions will also be taken as outlined below.

6.1.1 Water Level Trigger Rules

As discussed above, statistical analysis will form the initial part of defining trigger values. Due to considerable variability in both water level behaviors and water chemistry across the site (refer **Section 3.3**) as well as different bores designed to monitor for different risks (refer **Section 3**), numerous rules or analytical techniques must be used to determine an initial trigger value. For water level, the following rules will be used to define a trigger value.

- Trigger Rule 1: 30-Day average water level - 2 x Std Dev
- Trigger Rule 2: 30-Day average water level - 3 x Std Dev and where applicable 3 month average TDS or Cl:B - 3 x Std Dev

- Trigger Rule 3: Historical low water level
- Trigger Rule 4: Predicted drawdown after 12 Months
- Trigger Rule 5: If the Pit water level reaches -15.5mAHD (this is not expected to occur during the 12 month pumping test).

Rules 1 – 3 are designed to ensure dewatering impacts in the DBG/PWT and outcrop areas of the UEVF remains low (i.e. protection of any unmapped GDE's). Rule 4 is designed to minimise the risk of water in the pit void is migrating unacceptably into the underling aquifer.

Rule 5 is designed to minimise the short-term risk of pit water migrating into the DBG and also reaching the level where historical ash was consolidated above RL -15m (north east corner of the mine) as an EPA licenced activity and covered with at least 1m of sandy clay overburden material. It is conservatively estimated that the volume required as of April 2021 for the pit water level to reach the base of the DBG (i.e. RL = -15m) is an additional 2.045GL (approx.) of water. Therefore, it is unlikely that the pit water level will rise to - 15mAHD during the period of the test as the addition of pumping test groundwater and average mine catchment baseflow/rainfall/runoff is 1.86GL (1.5GL from groundwater; 0.36GL from rainfall, runoff and baseflow). The volume of 0.36GL has been the average annual volume of water (minus evaporation) entering the waterbody based on the last 60 months (5 years).

For each trigger bore, the relevant trigger rule and corresponding trigger value is presented in **Table 6-1** and shown graphically in **Figure 6-3** to **Figure 6-7**.

The use of standard deviations (measure of the variation or spread of a set of data which is equal to the square root of the variance) in monitoring data to assess potential groundwater impacts is common. This approach is used by Barwon Water to highlight potential impacts arising from the operation of Barwon Water's Bulk Entitlement for the Anglesea borefield. To assist in what a standard deviation may mean within a dataset, refer **Figure 6-1**. As an example, an outlier can be identified as a data point which is greater than four standard deviations from the mean (U.S. EPA 2009). If a data point falls outside 2 or 3 standard deviations, it is generally a good indication that change is occurring.

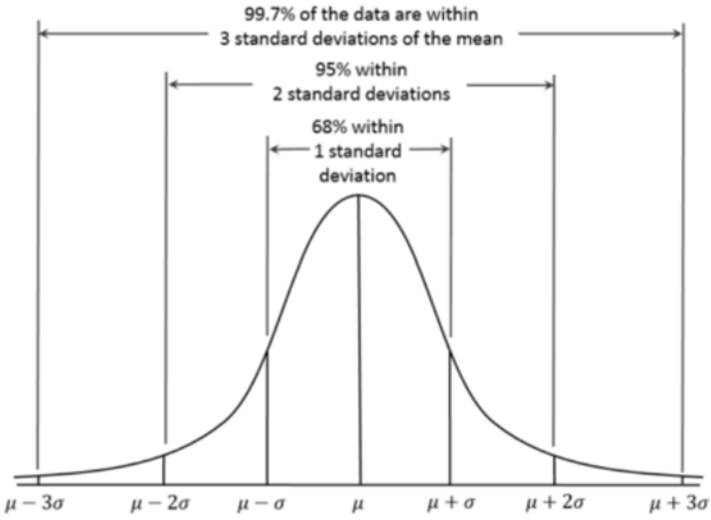

Figure 6-1 Normal distribution curve showing mean (μ), standard deviation (σ) and equivalent percentiles (U.S. EPA 2009)

6.1.2 Barwon Water Anglesea Borefield Trigger Levels

As discussed in **Section 2.2.2**, Barwon Water have 42 observation bores that monitor groundwater levels across the Anglesea catchment (**Figure 4-2**). These observation bores are located at different depths to monitor groundwater levels in different geological formations; in the PWT/DBG, UEVF and LEVF aquifers. Barwon Water holds a bulk entitlement to extract groundwater from the LEVF.

As part of Barwon Waters LEVF Bulk Entitlement, two key bores have been assigned groundwater level triggers to ensure groundwater levels can continue to support potential GDEs. These bores measure groundwater levels in the PWT (P8) in the Anglesea swamp and in the UEVF (P19), overlying the LEVF. It is the combination of groundwater levels in both of these bores that is important. If groundwater levels in both bores fall below a certain threshold level, then action must be taken – including reducing or ceasing pumping – to prevent any potential impacts to GDEs. The threshold level (also known as a "trigger") is determined by comparison to a control bore, to account for climatic influences on groundwater levels. The control bore (P17) is located in the Salt Creek swampland which is deemed outside the area of influence from operation of the Anglesea Borefield. This means the control bore provides a useful comparison of the natural variation in groundwater levels due to seasonal conditions.

Schedule 2 of the Bulk Entitlement Order (Anglesea Groundwater) 2009 sets out the method for calculating the Barwon Water trigger levels.

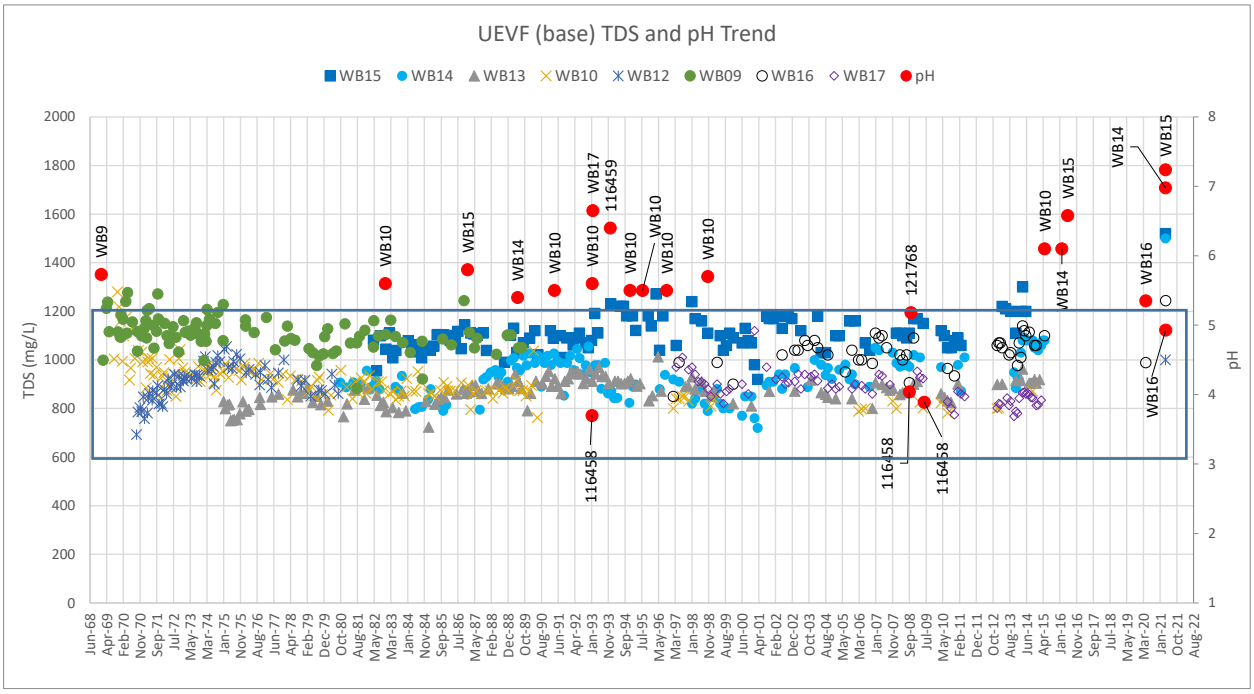
Alcoa will obtain the groundwater level information from Barwon Water for P8, P12, P17 and P19 groundwater bores on a monthly basis during the 12 Month Pumping Test including the Barwon Water trigger assessment for P8 and P19. These levels will be reported and incorporated along with Alcoa's data discussed in **Section 7.4.1**.

6.1.3 Water Quality Trigger Rules

Water quality triggers will be applicable to bores UEVF MB 3, 5, 7 and 8 as these bores are designed to monitor for potential migration of pit water into the UEVF. The trigger values will be based upon salinity (TDS) and Cl/B will be defined after 3 months of collation of baseline data. The resulting water quality trigger value will be determined by using the same method as the rule 2 water level trigger (e.g. average monthly Cl/B or TDS - 3 x Std Dev).

The reason why no water quality triggers are initially defined as follows:

- Water quality is a lagging indicator compared to water level. As water level triggers will be set (and are designed to mitigate the migration of water from the pit into the aquifer), achieving breakthrough in water quality values relating from the migrating pit water is unlikely.
- The initial round of TDS within the newly drilled bores around the mine is highly variable ranging from 194 mg/L (UEVF MB7) to 3,919 mg/L (UEVF MB04), refer **Table 4-4**. Furthermore, and generally, groundwater quality is highly variable across the site as evidenced in the annual groundwater monitoring events undertaken across the Power Station since 2006 (dataset sent to SRW March 29, 2021) also refer **Figure 6-2**. This makes setting groundwater triggers that can be representative of potential dewatering impacts difficult to justify.
- A comprehensive suite of water chemistry data (refer **Table 7-2**) is being collated on a monthly basis and will be subject to monthly analysis (same as water level), any outliers or changes in beneficial use segment will be highlighted and discussed at the monthly TRG meeting.



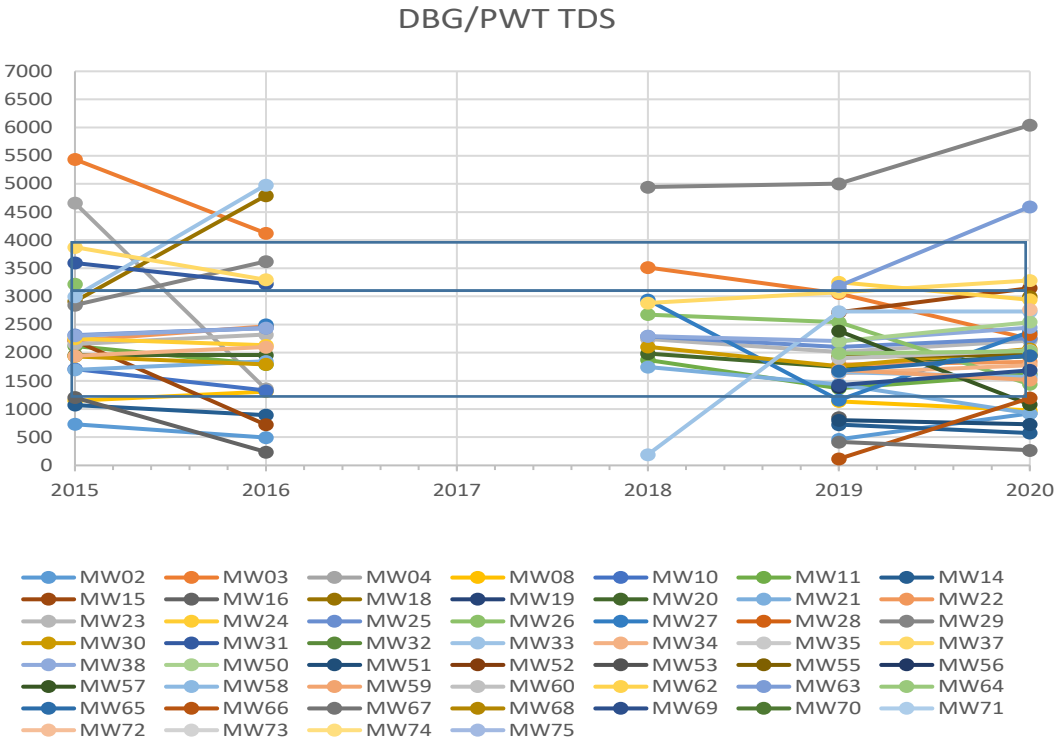


Figure 6-2 Historical TDS in the UEVF aquifer (Top) and DBG/PWT aquifer (Base). Blue Zone represents Segment A2. Orange represents Segment B and the green zone represents Segment C.

6.2 Trigger Level Summary

Table 6-1 presents the summary of water level triggers and how each trigger is related to risk. Note, as discussed in **Section 6.1.3**, water quality triggers based on TDS, chloride and boron will be defied after 3 months of data from bores UEVF MB 3, 5, 7 and 8.

Table 6-1 Summary of Water Level Triggers and Relationship to Risk

Bore ID	Aquifer Monitored	Monthly Groundwater Decline Trigger Level (m)	Monitored Risk (refer Section 3.1)	Risk Evaluation
116459	Lower Zone UEVF	Rule 1 = 0.14 Rule 2 & 3 = 0.6 Rule 4 = N/A due to historical declining trend	Risk 2 - Pumping of groundwater resulting in a reduction of baseflow to surface water systems and potential GDE's	**Uncontrolled risk ranking:** Low. No mapped GDEs present in the UEVF. Other mapped GDE are reliant on <10% baseflow contribution (refer GHD 2021. This bore has a history of declining water levels since the millennium drought (refer **Figure 3-1**). Numerical modelling suggests no impact will be observed at this location. Monitoring this bore will be used to manage drawdown risks where the aquifer may outcrop at some distance away from the pumping bore.
WB5		Rule 1 = 0.45. Rule 4 = 17. Rule 2 and 3 are not applicable as impacts are expected and necessary within the bore and the historical low is based on a larger pumping rate.		**Uncontrolled risk ranking:** Low. No mapped GDEs present in the UEVF. Other mapped GDE are reliant on <10% baseflow contribution (refer GHD 2021). (Note: Impact is expected in this bore as the purpose of the pumping test is to cause dewatering impacts). Using the Theis Method and assuming: • no leakage (i.e. very conservative) • The lower sands of the UEVF outcrop at the outer margins of the UEVF (refer Figure 4-5 of the GIA; e.g. near Bore 121768 at the closest point to the pumping bore). • Constant pumping rate (Q) at WB16 = 4320 m^3/d. • Aquifer storativity (S) = 0.00006. • Transmissivity (T) = 187 m^2/d. The results indicate 13m of drawdown after 30 days and 18m after 1 year. Numerical modelling suggests ~17m of drawdown after 1 year.
MW33	PWT/DBG	Rule 1 = 0.05 Rule 2 = 0.10 Rule 3 = 0.17. Rule 4 = N/A (insufficient history)	Risk 2 - Pumping of groundwater resulting in a reduction of baseflow to surface water	**Uncontrolled risk ranking = low.** Mapped GDE are reliant on <10% baseflow contribution (refer GHD 2021), these are generally located >5km from the site (mid catchment). At the site, surface water systems are losing systems, adoption of rule 2 or 3 will have no impact on lowering the risk. However, there may

Bore ID	Aquifer Monitored	Monthly Groundwater Decline Trigger Level (m)	Monitored Risk (refer Section 3.1)	Risk Evaluation
MW64		Rule 1 = 0.08 Rule 2 = 0.1 Rule 3 = 0.20 Rule 4 = N/A (insufficient history)	systems and potential GDE's	be times that vegetation may receive some groundwater contribution and/or surface water receives partial baseflow from perched water systems following heavy rainfall. Calculating this impact in a simplistically and conservatively way; a 0.2m decline in an unconfined aquifer system with a Sy of 0.2 would mean annually, 40mm (Rainfall= Sy x ΔS) of rainfall over this area would be required to replace this storage. In reality, recharge also gained from runoff and bank infiltration would mean the actual rainfall required would be much lower.
UEVF MB3*	Upper zone UEVF	Rule 1 = 0.20 Rule 2 = 0.22 Rule 3 = 0.60 Rule 4 = N/A (insufficient history)	Risk 5 - Placing 1.5GL of water into the pit void results in mine water migration into the UEVF	**<u>Uncontrolled risk ranking = low.</u>** Numerical modelling indicated this aquifer zone should not experience any drawdown impacts Underlying the mine water body is a 1-5m thick clay unit. This is referred to as the basal clay. Laboratory permeability testing of clay lenses encountered in MB7 averaged $1x10^{-9}$m/s ($8.6x10^{-5}$ m/d). To estimate the leakage related risks resulting from a 0.4m pressure decide in the underlying aquifer, the following equation can be used (Seepage velocity =(-K i) / n). Assuming: • hydraulic conductivity (K) = $8.6x10^{-5}$ m/d • Hydraulic gradient (i) = 0.4 (0.4m decline under the basal clay) • Porosity (n) = 5% After 1 year, the water will have potentially migrated up to 25cm through the clay.
UEVF MB5		Rule 1 = 0.20 Rule 2 = 0.22 Rule 3 = 0.60 Rule 4 = N/A (insufficient history)		
UEVF MB7		Rule 1 = 0.20 Rule 2 = 0.22 Rule 3 = 0.60 Rule 4 = N/A (insufficient history)		
UEVF MB8*		Rule 1 = 0.20 Rule 2 = 0.22 Rule 3 = 0.60 Rule 4 = N/A (insufficient history)		
DBG MB3, 5, 7, 8	DBG	Rule 5 = - 15.5mAHD	Risk 6 - Placing 1.5GL of water into the pit void results in the DBG and consolidated ash material to become saturated	**<u>Uncontrolled risk ranking = low as >2GL of water is required to reach -15mAHD.</u>** The DBG horizon is at RL-15m and also the level where historical ash was consolidated above RL -15m (north east corner of the mine) as an EPA licenced activity and covered with at least 1m of sandy clay overburden material. This trigger will provide a precursor to complete the historical analytical and numerical modelling with ERR/EPA (commenced in 2017) to understand and finalise any associated risks.

Trigger Rule 1: 30-Day Average Water level - 2 x Std Dev
Trigger Rule 2: 30-Day Average Water level - 3 x Std Dev and 3 month Average TDS or Cl:B - 3 x Std Dev (not yet calculated)

Trigger Rule 3: Historical Low Water Level
Trigger Rule 4: Predicted modelled drawdown after 12 Months
Trigger Rule 5: If the level of Pit water reaches - 15.5mAHD.

*Bores UEVF MB3 and UEVF MB8 are either in the process of being installed or not yet equipped with a data logger (i.e. only recently been installed). Trigger levels for these bores will be the same as UEVF MB5 and UEVF MB7 and will be confirmed after 3 months of data. As described, the risk of dewatering impacts in this aquifer is low. As a result, waiting 3 months before confirming a trigger should not increase the risk.

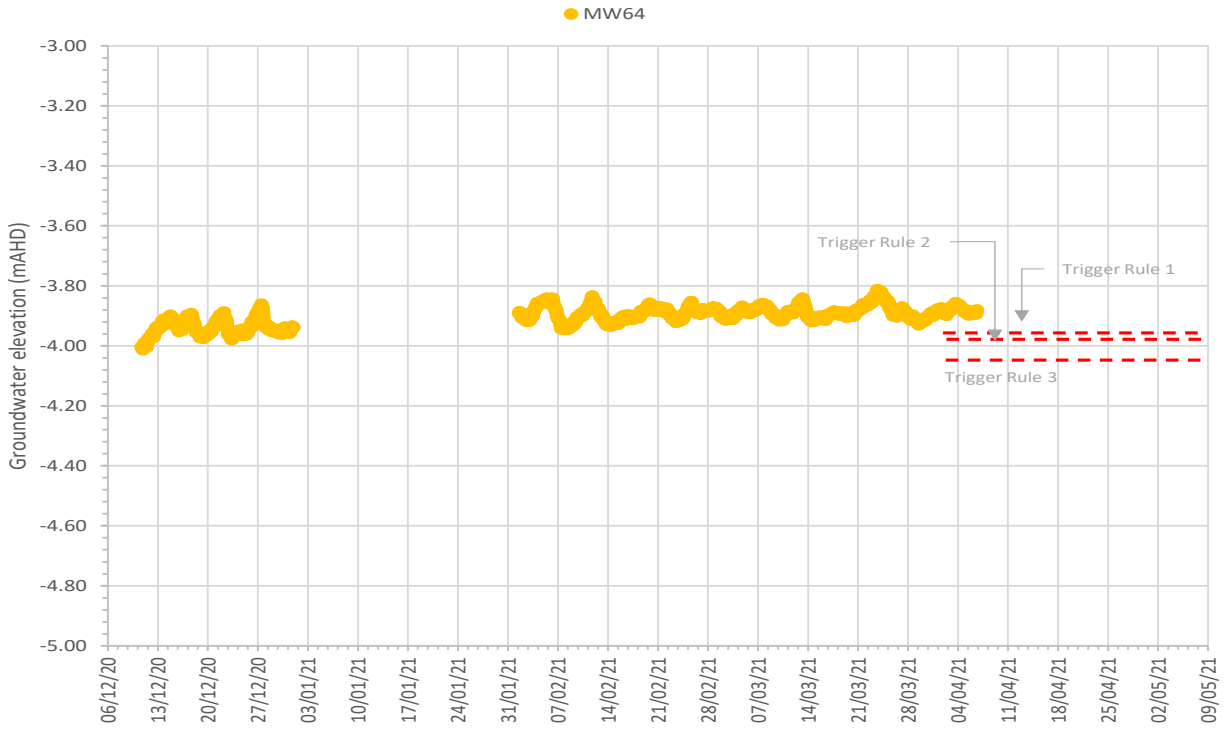

Figure 6-6 MW64 Hydrograph and Trigger Indicators

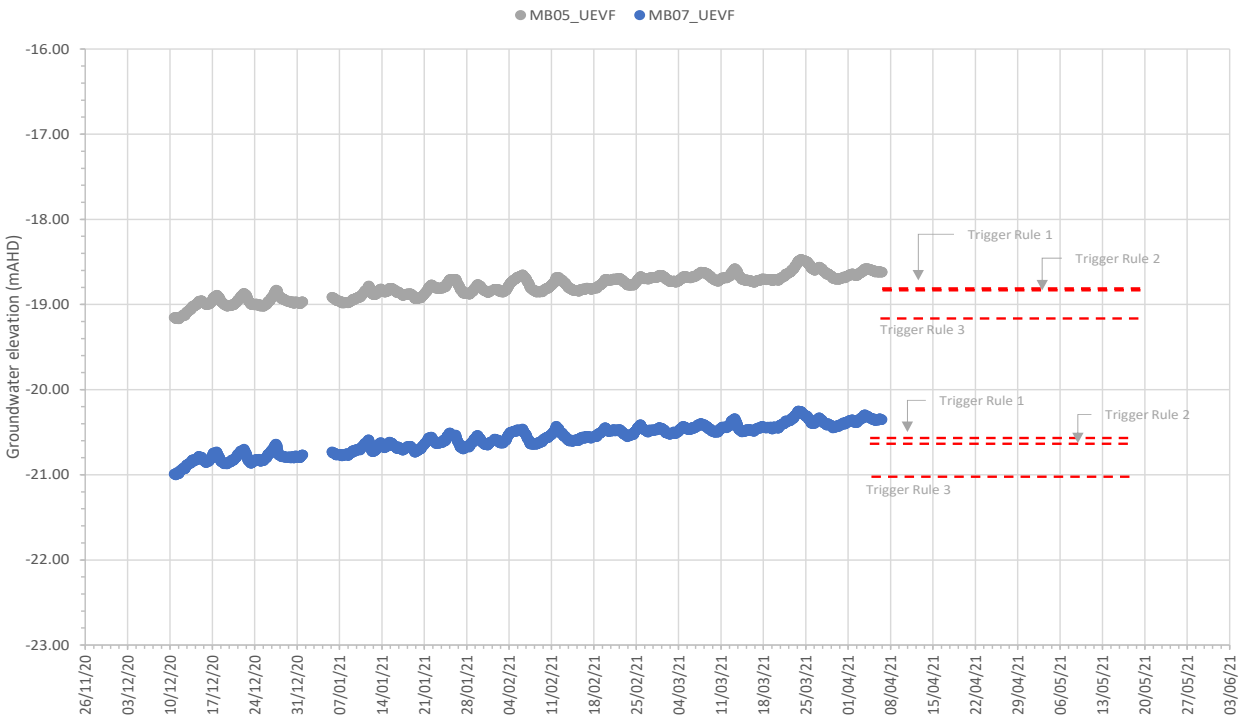

Figure 6-7 UEVFMB05 and UEVF MB07 Hydrograph and Trigger Indicators

6.3 Trigger Response Actions

As discussed in **Section 6.1** and **6.2** and summarised in **Table 6-1** trigger levels based on 5 different rules have been initially set. **Table 6-2** discussed the relevant actions that will be undertaken if a trigger level is observed.

Table 6-2 Actions if Trigger Level is Observed

Trigger Rule	Recommended Action	Relevant Bores Trigger is Applicable
Rule 1 (30-Day Average Water level - 2 x Std Dev)	Continue pumping but analyse water quality suite such as ion ratio trends to allow for a rapid assessment in case level continues to fall.	All bores except WB05
Rule 2 (30-Day Average Water level - 3 x Std Dev and 3 month average Cl:B or TDS - 3 x Std Dev)	Scale back pumping rates by 25% unless otherwise agreed with the Co-regulators TRG if: a. Rule 2 water level trigger is reached and b. there is no other identified reason for the decline (e.g. hydrographic recession following episodic recharge). Scale back pumping rates by 50% unless otherwise agreed with the Co-regulators TRG if: a. Rule 2 water level trigger is reached, and b. Rule 2 water quality (TDS or Cl/B) trigger is reached, and c. there is no other identified reason for the decline.	All bores except WB05
Rule 3 (Historical Low Water Level)	Scale back pumping rates by 50% unless otherwise agreed with the Co-regulators TRG if: a. the water level in the bore has reached its historical minimum, and b. there is no other identified reason for the decline (e.g. failed/blocked bore or climatic considerations).	All bores except WB05
Rule 4 (Water level exceeds 12 month modelled Drawdown	Scale back test by 25% each month until pressure increases above modelled drawdown unless otherwise agreed with the Co-regulators TRG.	WB05

Trigger Rule	Recommended Action	Relevant Bores Trigger is Applicable
Rule 5 Pit water level exceeds -15.5m AHD meaning Pit water may enter the DBG where historical buried Ash is located	The recommended actions are based upon an initial risk assessment undertaken in 2017 refer draft MRCP (EHS Support 2017 Technical Appendix K – Ash Assessment) which indicated that under steady state gradient, a conservative particle of water would take 159 years to move into the receiving environment. On this basis, the following actions related to pit water level are proposed for the pumping test: a. Within 9 months of the commencement of the pumping test, Alcoa to update and finalise the 2017 risk assessment in liaison with ERR/EPA and resolve outstanding risk issues. b. Stop the pumping test if the water level exceeds RL -15.5m unless otherwise agreed at the Co-Regulators Forum, with agreement to be dependent on item a above.	Nil. Applicable to pit water level, however DBG MB04 is the closest bore to Ash burial location.

Note if a trigger is observed, before any action is undertaken, the value will be verified through manual gauging. Additionally, if a statistically significant or anomalous water quality result is observed, the following specific response actions will be considered:

- Identify specific bores affected and review historical data.
- Re-sample and re-analyse to confirm the extent of change to water quality including a revised analytical suite if warranted.
- Assess all potential contributing factors to the change in water quality (e.g., groundwater migration from the mine, non-mine related activities and sustained below or above average rainfall).
- Evaluate potential site-specific environmental values at risk from changes to water quality.
- Re-evaluate trigger values based on new data, beyond which the water quality would be unfit for its intended purpose, in consultation with SRW (likely to be a direct reference to published water quality guidelines but may include derivation of location-specific guidelines for key parameters).

In addition to the actions listed above, as discussed in **Section 6.1.2**, Barwon Water will also provide monthly data for the Barwon Water trigger bores including if a trigger has been crossed. In the event that a Barwon Water trigger is crossed, Alcoa will initiate a review of potential causes in conjunction with Barwon Water with the result of this review and any recommendations to be discussed with the Technical Working Group.

7 Monitoring and Sampling Plan

7.1 Monitoring Activities and Elements

Monitoring activities will vary from general site observations to in-situ measurements and sample collection for laboratory analysis. The level (type and frequency) of monitoring included in this monitoring plan has been established to assess changes in groundwater and the mine pit void water body as part of the 12-month groundwater pumping test.

Alcoa and other parties have conducted periodic historical sampling that provides some data to assist in defining baseline conditions in groundwater and the mine pit void water body. However, and as noted above further monitoring and sampling is required to fully characterise these systems and assess potential risks associated with the 12-month pumping test.

Note that monitoring long term water levels/quality has always been considered to be a part of the MRCP, and Alcoa has always intended to monitor over the long term to the satisfaction of various regulators providing oversight of that activity. As such, Alcoa intends that the data loggers and sampling program (at an appropriate frequency to be determined) will remain in place following the pumping test until such time as it is considered that they are considered no longer warranted. This will be further informed by the data, results and outcomes of the pumping test

7.2 Groundwater Level Monitoring

As discussed above and shown on **Figure 4-2** and **Figure 4-3** groundwater monitoring locations have been established by Alcoa and Barwon Water within the PWT/DBG, UEVF (upper and deeper zone) and LEVF.

It is proposed that continuous (daily) groundwater level and pressure monitoring be undertaken in all nominated monitoring and trigger bores, including by Barwon Water for those owned by Barwon Water (bores P8, P12, P17 and P19). These results will be downloaded monthly. Groundwater level monitoring will be collected using two primary data collection methods:

- Continuous monitoring using Solonist Levelogger.
- Manual gauging prior to each groundwater sampling event.

The groundwater monitoring program is designed to validate the findings of the numerical groundwater model and demonstrate the absence of lateral or vertical migration and/or changes in water quality that could affect potential beneficial uses of the UEVF and LEVF.

7.3 Sampling Program

Mine pit void water body and groundwater sampling will be conducted in accordance with the requirements of publication Victorian EPA (2009). All identified monitoring bores that form part of the monitoring network will be sampled using laboratory supplied bottles and sent to a National Association of Testing Authorities (NATA) accredited laboratory for analysis. Groundwater sampling of Barwon Water trigger bores is not planned.

To acquire the sample, bores will be pumped or sampled with a bailer allowing a minimum of two bore volumes to be purged. A sample will then be taken once stable field parameters (pH, EC, T and Eh) are achieved. Grab samples will be taken from WB16 where pumping is under continuous operation. Field parameters will also be recorded at the time of sampling.

The sampling will be undertaken in accordance with the schedule shown in **Table 7-1**. Sampling will be conducted in accordance with QA/QC procedures outlined below.

There will be an opportunity to re-evaluate the frequency of monitoring and analytical suite based on actual data collected throughout the test, to be reviewed with SRW and as part of the proposed TRG where appropriate.

7.3.1 Analytical Suite

The groundwater monitoring program is designed to validate the findings of the numerical groundwater model and demonstrate the absence of lateral or vertical migration and/or changes in water quality that could affect potential beneficial uses of the UEVF. The analytical suite proposed is shown on **Table 7-2**. Additional analytes may still be collected to support data objectives attributed to potential mine pit void water body amendment activities and if collected will form part of the monthly notifications.

Groundwater sampling will be conducted in accordance with QA/QC procedures below.

7.3.2 Field Duplicate: Intra-Laboratory Duplicate Samples

During months 1-7, 9 and 12 (**Table 7-1**), one bore will be selected for a duplicate sample. The duplicate sample is to be analysed for the same analytes as the primary sample. This sample is used to assess the repeatability of the sampling and analytical processes. It is a measure of intra-laboratory precision and the repeatability of sampling.

7.3.3 Rinsate (or Equipment) Blank

One rinsate blank per day during sampling will be collected and analysed for the same analytes as the field sample collected immediately prior to decontamination of the field equipment. Rinsate samples are collected to assess if decontamination of sampling equipment has been conducted adequately to minimise the potential for cross-contamination between sampling points.

Table 7-1 Adopted Sampling Program

7.4 Reporting and Communication Requirements

7.4.1 Monthly Factual Report

Following each monthly gauging and sampling round, a monthly report will be prepared inclusive of extraction rates from WB16 (daily volume extracted, daily limit, total volume extracted year to date and

yearly limit), manual groundwater levels and datalogger data, and water quality results. The report will also present the data against trigger levels and outline any trigger actions, contingency plans and provide recommendations for any modifications to the monitoring program.

The monthly report will be provided to SRW, key stakeholders and the community within four weeks of the end of each calendar month.

7.5 Continual Improvement

This Monitoring Plan will be reviewed periodically in response to monitoring results. Issues to be considered during this review includes but is not limited to:

- Re-assessing the suitability of the monitoring and trigger network bores.
- Re-evaluating the frequency of monitoring and analytical suite based on monthly data.
- Developing revised trigger values based on the collection and analysis of more than 3 months of daily baseline data.

In addition to this, a Co-regulator Forum Technical Reference Group has been established which will provide a regular opportunity to discuss any issues, risks or improvements and provide oversight of the 12-month groundwater pumping test throughout the test period.

7.5.1 Barwon Water and Alcoa Communication

Any amendments to pumping each Borefield, including both a UEVF and LEVF dual pumping sub 'test' (the detail to be agreed with Barwon Water) will be appropriately communicated to the parties including SRW in advance to ensure that the proposed hypothesis are captured and tested during the One Model approach and any impacts are attributed to pumping amendments which can be explained in the monthly reporting obligations.

7.5.2 Updates to the Environment Protection Act 2017

Alcoa also understands that from 1 July 2021, the State Environment Protection Policy (Waters) will be replaced by the Environment Reference Standard. On this basis it is noted that the groundwater segments will not change at this time with the new Act, and the environmental values (which replace beneficial uses) will not change in relation to the groundwater segment, the introduction of the new Act does not immediately impact the framework developed to define triggers levels at this time. Notwithstanding this the Monitoring Plan will be updated to include discussion of the new legislative changes associated with the Act, subordinate legislation, Environment Reference Standard and associated guidelines. If the Plan requires updating from 1 July 2021 then the appropriate changes will be made.

8 One Model (Proposed)

Alcoa and Barwon Water have in principle agreed to work together to refine and update Barwon Waters existing "Anglesea Groundwater Model" inclusive of both Alcoa's and Barwon Water's latest information, to provide a more comprehensive and detailed groundwater model for the region. This is referred to as the One Model approach. The existing Barwon Water model was initially developed by GHD between 2007 and 2013 and has been previously used to understand potential impacts associated with Barwon Water's Bulk Entitlement from the LEVF. Further details on this model can be found in GHD (2013).

Alcoa and Barwon Water anticipate the kickoff of the One Model development from May 2021 with EHS Support and GHD respectively involved for both parties.

As part of the development of the One Model, Alcoa and Barwon Water have kicked off discussions with SRW and DELWP regarding the inclusion of an appropriate Independent Peer Reviewer (IPR), potentially appointed the regulators, on the basis that the IPR would be involved in the process (with EHS Support and GHD) from kick off.

The model will be built in either MODFLOW-USG or MODFLOW 6 and represent a 3D recharge runoff groundwater flow model which will simulate groundwater flow and surface water / groundwater interactions between all underlying units to the base of the LEVF and (inclusive of the mine pit). Once the model has been completed and an Independent Peer Reviewer has verified the model is fit for purpose, the model will be made available as a stand-alone model to both Barwon Water and Alcoa to run predictive simulations.

Lithological and geophysical data obtained from the recent drilling of the new monitoring bores around the mine pit void as well geophysical data from the deeper bores nearer the Power Station will help refine the model layers (isopach's) in the UEVF and DBG within the vicinity of the mine pit void. Laboratory permeability testing of geological core will also be used to improve hydrogeological parameters within the upper sections of the UEVF.

During the 12-month groundwater pumping test and in discussion between Alcoa and Barwon Water, it is also proposed that Barwon Water will stress the LEVF in a planned manner by pumping certain bores. The monitoring response (along with geophysical logging) will help determine any potential aquifer interactions which can then be further considered by both Alcoa and Barwon Water.

The results of the first 6 months of the 12-month groundwater pumping test will be used to help calibrate the model and verify the model predictability. The groundwater model will then be used by Alcoa to inform a risk and impact assessment for any potential UEVF licence amendment following the 12-month pumping test.

COPY OF RECORD IN THE VICTORIAN WATER REGISTER

TAKE AND USE LICENCE

under Section 51 of the Water Act 1989

The information in this copy of record is as recorded at the time of printing. Current information should be obtained by a search of the register. The State of Victoria does not warrant the accuracy or completeness of this information and accepts no responsibility for any subsequent release, publication or reproduction of this information.

This licence does not remove the need to apply for any authorisation or permission necessary under any other Act of Parliament with respect to anything authorised by the take and use licence.

Water used under this entitlement is not fit for any use that may involve human consumption, directly or indirectly, without first being properly treated.

The Authority does not guarantee, by the granting of the licence, that the licensee will obtain any specific quantity or quality of water. The Authority is not liable for any loss or damage suffered by the licensee as a result of the quantity of water being insufficient or the quality of the water being unsuitable for use by the licensee at any particular time or for any particular purpose.

This take and use licence entitles its holders to take and use water as set out under the licence description, subject to the conditions that are specified.

Licence Holders

Alcoa Of Australia Ltd**

Licence Contact Details

Alcoa Of Australia Ltd** CAMP ROAD ANGLESEA
VIC 3230

Licence Description

Expiry date	30 Jun 2024
Status	Active
Authority	Southern Rural Water
Name of waterway, aquifer or works	LTA-Jan Juc
Water system type	Groundwater
River basin or groundwater unit	Jan Juc (GMU)
Licence volume	4000.0 megalitres
Licence volume adjusted for temporary trade	4000.0 megalitres
Method of taking	Direct extraction from Groundwater
Period during which water can be taken	01 Jul - 30 Jun inclusive
Use of water	Industrial or commercial use - as well as domestic and stock use
Trading zone	Jan Juc LTA

Licence Volume Details

Licence volume	4000.0 megalitres
Licence volume adjusted for temporary trade	4000.0 megalitres

Temporary volume transaction details

Approval date	*Volume traded (ML)*	*Expiry date*
Nil		

Extraction Point Details

Easting	*Northing*	*Zone MGA*	*Location description*

Conditions

This take and use licence is subject to the following conditions:

Method of taking

1 Water may only be taken under this licence if it is taken by the methods expressly approved by this licence.

2 The licence holder must at all times provide the Authority with safe access to inspect all works and appliances used to take water under this licence.

Take location

3 Water may only be taken under this licence if it is taken at the location described as follows: the land parcels identified on this licence.

Take volume and rate

4 The volume of water taken under this licence in any twelve-month period from 1 July to 30 June must not exceed the licence volume, less any volume that has been temporarily transferred to another person or location.

5 The maximum volume that may be taken under this licence in any one day is 39.8 megalitres per day shared between 7 bores.

Temporary transfers to the licence holder

6 If there has been a temporary transfer of another licence to take water at the location, and use water on the land, specified in this licence: a) the extra volume of water taken must not exceed the volume transferred, and b) all the conditions of this licence apply to the taking and using of water consequential to the transfer.

Rosters and restrictions

7 When directed by the Authority, water must be taken in accordance with the rosters and restrictions determined by the Authority, and advised to the licence holder.

Metering of water taken and used

8 Water may only be taken under this licence if it is taken through a meter approved by the Authority.

9 Meters must be installed , in accordance with the specifications set by the Authority, at the licence holder's expense.

10 Meters used for the purpose of this licence are deemed to be the property of the Authority.

11 The licence holder must at all times provide the Authority with safe access to meters for the purpose of reading, calibration or maintenance.

12 The licence holder must notify the Authority within one business day if the meter ceases to function or operate properly.

13 The licence holder must, if required by the Authority, keep an accurate record of the quantity of water taken under this licence and allow the Authority to inspect this record at all reasonable times, and provide a copy of the record when requested.

14 The licence holder must not, without the consent of the Authority, interfere with, disconnect or remove any meter used for the purposes of the licence.

15 The Authority may, if it deems necessary, make an estimate of the total volume of water taken under this licence.

Use of water

16 Water taken under this licence may only be used on the land, and for the purposes, specified in the licence.

17 The licence holder must at all times provide the Authority with safe access to inspect the land on which water is licensed to be used.

Operation and maintenance

18 The licence holder must keep all works, appliances and dams associated with this licence,

including outlet pipes and valves, in a safe and operable condition, and free from obstacles and vegetation that might hinder access to works.

Preventing pollution

19 The licence holder must, construct and maintain bund walls around any hydrocarbon-fuel-driven engine, motor, fuel storage, or chemical storage used in connection with this licence, in accordance with the timeframe, specifications, guidelines and standards prescribed by the Authority.

Managing groundwater infiltration

20 The maximum volume of water that may be applied to the land referred to in the licence in any 12-month period from 1 July to 30 June is the annual use limit which is equal to the licence volume, or if the annual use limit is adjusted by the Authority on account of seasonal conditions this adjusted annual use limit.

Managing drainage disposal

21 Where water use results in drainage from the land specified in the licence, that drainage water must be disposed in ways that meet the standards, terms and conditions adopted from time to time by the Authority.

Fees and charges

22 The licence holder must, when requested by the Authority, pay all fees, costs and other charges under the Water Act 1989 in respect of this licence.

END OF COPY OF RECORD

Appendix B Risk Assessment

Area: Anglesea Mine 12 Month Groundwater Pumping Test Risk Control Assessment					Date: December 22, 2020					Participants: W Sharp, J Osborne, A Robertson, N Marris, C Smitt (EHS)		
Element	**Mining Hazard**	**Potential Risk Source (incl activity or circumstance)**	**Potential Receptors at Risk**	**Control Measures (Physical and Administrative)**	**Performance Objective, Standard OR Criteria for Each Control OR combination of control measures**	**Consequence**			**Likelihood**	**Risk Rating**	**Monitoring and Reporting**
						Public Safety	**Community facilities, including property and infrastructure**	**Land and Environment**			
1	Surface Water	- Activity - Plant and Equipment Failure (UEVF groundwater loss to potential receptors)	- Anglesea River - Salt Creek	- Extraction bore site earthen bund to provide separation from Anglesea River - earthen bund and piping redundancy/sleeving to prevent any water leak from entering Anglesea River - Pipeline route to provide separation from Salt Creek Diversion Channel - Pipeline commissioning procedure to be developed - Pipeline & equipment inspections twice per day - Regular equipment maintenance by supplier for duration of test - Investigate instrumentation based automatic shutdown or notifications with equipment supplier - Anglesea Mine Water Management Plan	- No release of groundwater into the Anglesea River or Salt Creek. - Compliance with Alcoa EPA License 11429 condition LI_DW1 *You must ensure that surface water discharged from the premises is not contaminated with waste.* - compliance with Environment Protection Act 1970. *Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect.* - Compliance with Section 3.2(d) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
2	Surface Water	- Activity - groundwater extraction of up to 1.5Gl of UEVF results in reduction of baseflow to surface water (GDE's)	- Anglesea River - Salt Creek	- Groundwater impact assessment including groundwater modelling approved by SRW - SRW amended groundwater license conditions - Water Monitoring Plan -12 Month Groundwater Pumping Test including groundwater level and quality triggers to be approved by SRW - Daily and annual (1.5Gl) cap on extraction - Data logging and reporting of groundwater levels and quality - Installation of 16 new monitoring bores around the periphery of the mine void - Known multiple low permeability confining layers between receptors and extraction point - Anglesea Mine Water Management Plan - Monthly Technical Steering Committee review for regulators and agencies	- Compliance with Alcoa EPA License 11429 condition LI_DW1 *You must ensure that surface water discharged from the premises is not contaminated with waste.* - Compliance with Environment Protection Act 1970. *Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect.* - Compliance with Section 3.2(d) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Water Monitoring Report – 12 Month Groundwater Pump Test Monthly Report (as per SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status) - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting

Area: Anglesea Mine 12 Month Groundwater Pumping Test Risk Control Assessment					Date: December 22, 2020					Participants: W Sharp, J Osborne, A Robertson, N Marris, C Smitt (EHS)		
Element	**Mining Hazard**	**Potential Risk Source (incl activity or circumstance)**	**Potential Receptors at Risk**	**Control Measures (Physical and Administrative)**	**Performance Objective, Standard OR Criteria for Each Control OR combination of control measures**	**Consequence**			**Likelihood**	**Risk Rating**	**Monitoring and Reporting**
						Public Safety	**Community facilities, including property and infrastructure**	**Land and Environment**			
3	Surface Water	- Activity – Placement of 1.5Gl of UEVF groundwater into the mine void water body (consistent with accelerated mine void filling strategy) adversely impacting surface water quality	- Mine water body	- Historical water body water quality precludes beneficial uses (note that this is consistent with background surface waters including Anglesea River and Salt Creek) - UEVF water quality is higher quality than current mine water body. - Discharge of UEVF water will be below the pit water level to inhibit oxygenation of the water and mitigate geochemical reactions. - Water Monitoring Plan -12 Month Groundwater Pumping Test including mine void water quality to be approved by SRW - Mine water body is a physically closed system that is not able to discharge to surface water systems due to existing topography - Anglesea Mine Water Management Plan - Monthly Technical Steering Committee review for regulators and agencies	- Compliance with Alcoa EPA License 11429 condition LI_DL1.3 *You must ensure that the activities carried on at the premises do not do either of the following:* *a) cause detriment to any beneficial use which may be made of groundwater both within and beyond the boundary of the premises.* *b) pollute groundwater both within and beyond the boundary of the premises contrary to section 39 of the Environment Protection Act 1970* - Compliance with Environment Protection Act 1970. *Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect.* - Compliance with Section (43), 56 (a),(b) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Water Monitoring Report – 12 Month Groundwater Pump Test Monthly Report (as per SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status) - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
4	Groundwater availability	- Activity - groundwater extraction of up to 1.5Gl from UEVF that impacts third party or environmental beneficial users	- UEVF aquifer domestic users - LEVF Barwon Water	- Two nearest domestic users located 3 km southeast, 8.5 km northeast of the mine. - UEVF sits above the LEVF separated via the MEVF (aquitard). Due to an upward gradient from the LEVF to the UEVF, the only potential for impact to the LEVF is from pumping the LEVF itself. - Decommission of historical redundant power station bores where required. - Combined pumping test UEVF/LEVF agreed in principal with Barwon Water. - Plus all control measures described in Element 2 above.	- Compliance with Alcoa EPA License 11429 condition LI_DL1.3 *You must ensure that the activities carried on at the premises do not do either of the following:* *a) cause detriment to any beneficial use which may be made of groundwater both within and beyond the boundary of the premises.* *b) pollute groundwater both within and beyond the boundary of the premises contrary to section 39 of the Environment Protection Act 1970* - Compliance with Environment Protection Act 1970. Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect. - Compliance with Section (43), 56 (a),(b) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Water Monitoring Report – 12 Month Groundwater Pump Test Monthly Report (as per SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status) - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
5	Groundwater quality	- Activity - Placement of 1.5GL of UEVF groundwater into the mine void water body (consistent with accelerated mine void filling strategy) results in localised migration of mine void water into UEVF	- UEVF	- All control measures described in Element 2 above.	- Compliance with Alcoa EPA License 11429 condition LI_DL1.3 *You must ensure that the activities carried on at the premises do not do either of the following:* *a) cause detriment to any beneficial use which may be made of groundwater both within and beyond the boundary of the premises.* *b) pollute groundwater both within and beyond the boundary of the premises contrary to section 39 of the Environment Protection Act 1970* - Compliance with Environment Protection Act 1970. *Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect.* - Compliance with Section (43), 56 (a),(b) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Likely	Medium	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Water Monitoring Report – 12 Month Groundwater Pump Test Monthly Report (as per SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status) - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting

Area: Anglesea Mine 12 Month Groundwater Pumping Test Risk Control Assessment					Date: December 22, 2020						Participants: W Sharp, J Osborne, A Robertson, N Marris, C Smitt (EHS)
Element	**Mining Hazard**	**Potential Risk Source (incl activity or circumstance)**	**Potential Receptors at Risk**	**Control Measures (Physical and Administrative)**	**Performance Objective, Standard OR Criteria for Each Control OR combination of control measures**	**Consequence**			**Likelihood**	**Risk Rating**	**Monitoring and Reporting**
						Public Safety	**Community facilities, including property and infrastructure**	**Land and Environment**			
6	Groundwater quality	- Activity - Placement of 1.5Gl of UEVF groundwater into the mine void water body (consistent with accelerated mine void filling strategy) results in mine void water coming into contact with consolidated ash material (placed in the mine as a licensed activity under EPA License 11429)	- Consolidated ash material within mine (placed in the mine as a licensed activity under EPA License 11429)	- Ash material located in the southeast corner of the mine known to be located between RL-15 and -8m - Current mine water level is ~RL-21m, based on surveyed bathymetry the water level is expected to rise to ~RL-16m. As such no interaction between pit water and the ash material is expected. - All ash material is covered with at least 1m of overburden material (as approved by ERR). - EHS Support 'Ash Assessment' Study MRCP Appendix K submitted to ERR 28/9/2017 geochemical mixing and transport modelling indicated the discharge of ash porewater into UEVF groundwater or pit water body is likely to have a negligible effect on the receiving water chemistry and also indicated it would take up to 159 years for a particle of water to migrate out into the formation. - Monthly mine void water level to be surveyed and reported. - Plus all control measures described in Element 2 above.	- Compliance with Alcoa EPA License 11429 condition LI_DL1.3 *You must ensure that the activities carried on at the premises do not do either of the following:* *a) cause detriment to any beneficial use which may be made of groundwater both within and beyond the boundary of the premises.* *b) pollute groundwater both within and beyond the boundary of the premises contrary to section 39 of the Environment Protection Act 1970* - Compliance with Environment Protection Act 1970. *Note: In July 2021, the Environment Protection Amendment Act 2018 will come into effect.* - Compliance with Section (43), 56 (a),(b) State Environment Protection Policy (SEPP WoV, 2018)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Water Monitoring Report – 12 Month Groundwater Pump Test Monthly Report (as per SRW monthly groundwater pumping test report to all key stakeholders including updates on groundwater levels, quality and agreed trigger status) - Monthly Technical Steering Committee updates with key regulators and agencies - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
7	Noise Pollution	- Activity - Plant and Equipment	- Public safety	- Diesel generator located approx. 1300m from nearest resident, with significant vegetation and ridges in between. - Equipment maintenance regime in accordance with manufacturers specifications (approx. every 600 hours). - Diesel generator include appropriate engineered silencing canopy	- No detrimental noise emissions - Compliance with Alcoa EPA Licence 11429 - Amenity Condition for Noise (LI_A2) - Compliance with EPA Publication 1411 - Noise from industry in regional Victoria - Compliance with appropriate sections of the endorsed Work Plan 2011 (Schedule of Conditions)	Insignificant	Insignificant	Insignificant	Unlikely	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
8	Ground Instability	- Activity - Placement of 1.5Gl of UEVF groundwater into the mine void water body (consistent with accelerated mine void filling strategy) - Groundwater Level increase - Surface Water (erosion) - Geological Structure	- Public Safety - Flora and Fauna - Aboriginal Heritage - Infrastructure (Barwon Water pipeline, bores and power) - Infrastructure (powerlines) - Public Infrastructure (Coalmine Road and Messmate Track) - Private property (Anglesea Golf Club) - Crown Land disturbance	- Engineering control through geotechnical and hydrological design reducing overall slope angle - Independent peer review of the Geotechnical and Hydrological Design - Establishment by design of 20 metre set back to public infrastructure - Ground Control Management Plan - Water Management Plan - Construction informed by embankment compaction trials - Geotechnical inspections by trained personnel during construction - Geotechnical evaluation of survey data - Establishment of the Geotechnical Risk Zone (GRZ) - Surface drainage controls - Earthworks 'As Built Report' confirming compliance and that earthworks meet or exceed design criteria	- Creation of safe and stable slopes with probability of failure < 1 x 0.00001 - Compliance with relevant standards (ie. Guidance material for the assessment of geotechnical risk in open pit mines and quarries) - Maintain buffer to public infrastructure - Ensure slope construction is in accordance with engineering design (refer to separately submitted earthworks 'As Built' Report) - Early detection of geotechnical instability - Surface water erosion does not impact on geotechnical stability - Compliance with appropriate sections of the endorsed Work Plan 2011 (Schedule of Conditions)	Critical	Minor	Insignificant	Rare	Medium	- Daily supervision of works - Implementation of slope monitoring (to be agreed with ERR), analysis and reporting of data - Audit and reporting of contractor compliance against Ground Control Management Plan, Water Management Plan - Quarterly Geotechnical and surface water erosion Inspections and reporting - Incident reporting - Installation of 16 additional groundwater monitoring wells, monitoring, analysis and reporting of data - Community feedback and/or complaints and regulator feedback - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings

Area: Anglesea Mine 12 Month Groundwater Pumping Test Risk Control Assessment					Date: December 22, 2020						Participants: W Sharp, J Osborne, A Robertson, N Marris, C Smitt (EHS)
Element	**Mining Hazard**	**Potential Risk Source (incl activity or circumstance)**	**Potential Receptors at Risk**	**Control Measures (Physical and Administrative)**	**Performance Objective, Standard OR Criteria for Each Control OR combination of control measures**	**Consequence**			**Likelihood**	**Risk Rating**	**Monitoring and Reporting**
						Public Safety	**Community facilities, including property and infrastructure**	**Land and Environment**			
9	Erosion	- Activity - Pumping test pipeline unplanned release of water or uncontrolled discharge into water body	- Surface Water (contained within mine pit only)	- Pipeline placement at water body end for the last approx. 300m of its route into the engineered (concrete mat lined) drain 9 - Pipe discharge arrangement that extends out from the water body edge a distance of 5 to 10m, is floated towards the end to keep it off the water body floor - Pipe discharge arrangement appropriately fixed in position to minimise the risk of the discharge encroaching on the water body edge - Ground Control Management Plan - Water Management Plan	- No active erosion rill lines associated with pipeline - No active tunnel erosion on slopes or associated with pipeline - Compliance with appropriate sections of the endorsed Work Plan 2011 (Schedule of Conditions)	Insignificant	Insignificant	Insignificant	Possible	Low	- Daily supervision of works - Twice daily pipeline and equipment inspections including the discharge into the water body - Visual inspection for rill presence/absence/activity using accepted visual criteria for activity recording or rill location and dimensions - Inspection for tunnel erosion (including potential higher risk areas) for signs of seepage, ponding, or slumping - Visual assessment initiated after rainfall events > 20mm - Quarterly Geotechnical and surface water erosion Inspections and reporting - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting
10	Unmanaged Hazardous Material/Waste	- Activity - Plant and Equipment - Spill of fuel or oils	- Groundwater - Surface Water - Biodiversity - Ecosystem	- Use of a engineered bunded diesel fuel storage tank - Earthen bund construction around equipment laydown area as secondary containment - Suitably qualified and experienced contractors (equipment set up and/or refuelling) - Equipment refuelling procedure - Equipment maintenance regime in accordance with manufacturers specifications. - Supervision - Spill response procedure and equipment (ie spill kits)	- No uncontrolled spill of fuel or oil - Compliance with Alcoa EPA Licence 11429 Condition LI_G1. - Compliance with Waters SEPP - Compliance with AS 1940 - 2004 The storage and handling of flammable and combustible fluids - Compliance with DG Act 1985 and Regulation (Storage and Handling) 2012. - Compliance with appropriate sections of the endorsed Work Plan 2011 (Schedule of Conditions)	Insignificant	Insignificant	Insignificant	Possible	Low	- Daily supervision of works - Equipment maintenance records - Twice daily pipeline and equipment inspections including the discharge into the water body - Reporting via monthly ERR report and bimonthly Community Consultative Network meetings - Health and Safety and Environmental Incident reporting

Purpose

This guideline assists Tenement holders (mining licence, prospecting licence) proposing miningto plan, prepare and lodge a risk-based work plan or variation to an approved work plan (the work plan) under the *Mineral Resources (Sustainable Development) Act 1990* (MRSDA) and in accordance with the requirement for a risk-based work plan under Schedule 15 of the Mineral Resources (Sustainable Development) (Mineral Industries) Regulations 2013 (MRSD(MI)R).

An overview of the exploration project approval process is available here: http://www.energyandresources.vic.gov.au/__data/assets/pdf_file/0018/1144017/20140704-Overview-chart-exploration.pdfhttp://www.energyandresources.vic.gov.au/__data/assets/pdf_file/0018/1144017/20140704-Overview-chart-exploration.pdf

Tenement holders can prepare and lodge work plans using the online Resource Rights Allocation and Management (RRAM) system. RRAM is designed to administer and regulate Victoria's earth resources industries. RRAM enables work plans to be prepared, lodged, assessed, endorsed and approved online.

For access to RRAM and a guide to use RRAM please refer to: http://www.energyandresources.vic.gov.au/earth-resources/licensing-and-approvals

What is covered in this Guideline

Requirements under the Regulations and Schedule 15 of the Regulations	Information covered in this Guideline
Part 1—Required information— mining work 1. Description of work	Refer See Part B of this guideline
2. Identification of mining hazards	Refer See Part B of this guideline
3. Identification and assessment of risk	Refer See Part B of this guideline
4. Risk management plan	Refer See Part B of this guideline
5 Rehabilitation plan	Refer See Appendix 14
6 Community engagement plan	Refer See Appendix 13
Part 2—Stability requirements— declared mines	Information required under this clause is not described in this guideline.
Part 3—Fire risk management plan—coal mines	Information required under this clause is not described in this guideline.
32A Application for variation of work plan	Refer See Part D.

Who will use this Guideline

Earth Resources Regulation (ERR) requires an approved risk-based work plan when mining industry activities do not meet the requirements of section 40(2) of the MRSDA. Tenement holders of the mining project who require an approved risk-based work plan should use this Guideline.

A mining industry project must not commence without:

- a mining licence or a prospecting licence
- **an approved work plan** or compliance with Code of Practice provision under MRSDA
- **a planning permit** under the *Planning and Environment Act 1987* (P&E Act)
- **licence(s) and/or approval(s)** under other planning and environmental legislations (not mentioned above) that may affect the project
- compliance with other requirements under s42(1) of the MRSDA, including seven days' notice to the Chief Inspector under s42(1)(g).

A work plan is not required if the mining industry project meets requirements of s40(2) of the MRSDA:

(b) a licensee who holds a mining licence that—(i) covers an area of 5 hectares or less; and

(ii) does not involve underground operations, blasting, clearing of native vegetation or the use of chemical treatments; or

(c) a licensee who holds a prospecting licence that does not involve underground operations, blasting, clearing of native vegetation or the use of chemical treatments

If an approved work plan is not required, the site must comply with the Code of Practice for Low Risk Mines (available at http://www.energyandresources.vic.gov.au/earth-resources/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/code-of-practice-for-low-risk-mines).

How to use this Guideline

This section provides an overview of how to use this Guideline:

- Use Part E to understand whether you need to follow this Guideline to comply with the MRSDA and the MRSD(MI)R.
- Use Part A and Part B to propose a new mining industry project and lodge an application using RRAM.
- Use Part A, Part B and Part D to seek approval for proposed changes to existing work.
- Use Part C to understand how the approval is undertaken under the MRSDA for new projects and changes to existing mining industry projects
- Use Part F if you disagree with the ERR assessor about the assessment of the proposal.

The Guideline uses the following styles to guide you through the information:

- Green text in part B relate to fields in RRAM.
- Relevant extracts from the MRSDA and MRSD(MI)R are in italics and /or contained in a shaded box.
- Important information is presented in double line bordered boxes.

Processes are generally listed under headings containing the word 'Steps'.

Key steps – mining industry project approval

The key steps involves in the approval of a mining industry project are presented in figure 1.

Statutory steps

- Tenement holder obtains a mining licence or a prospecting licence.

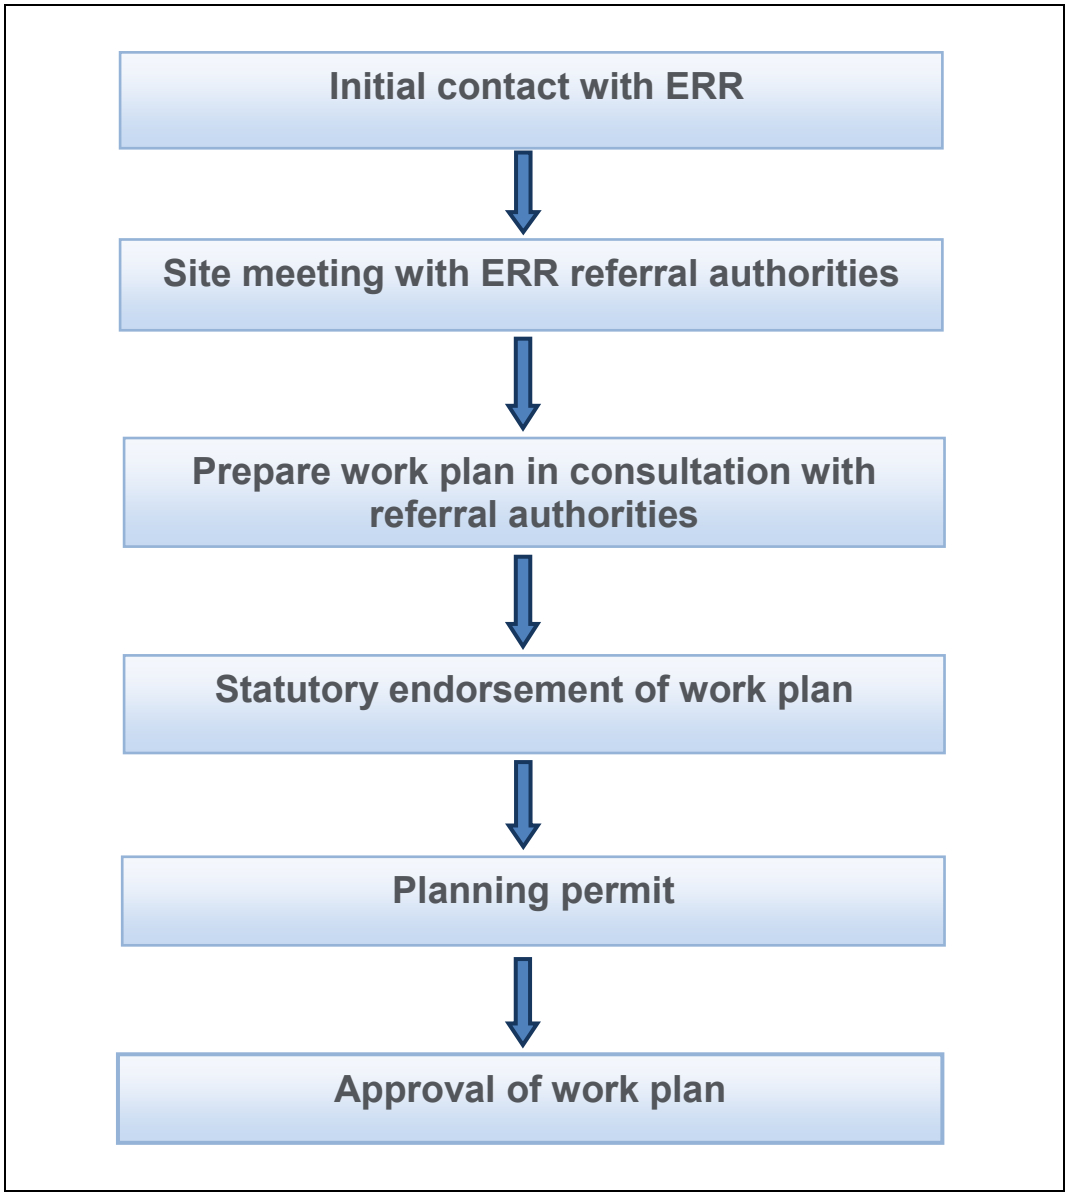
Non-statutory steps

- Tenement holder establishes contact with ERR within the Department of Economic Development, Jobs, Transport and Resources.
- Tenement holder schedules a site meeting with the department and the referral authority(s).
- Tenement holder prepares a risk-based work plan using RRAM online system.

Statutory steps

- Tenement holder lodges a risk-based work plan with the department.
- The department gives a copy of the risk-based work plan to the referral authority(s) within 28 days of receipt of the plan.
- Within 28 days, the referral authority(s):
    - agrees to statutory endorsement, or
    - agrees to statutory endorsement subject to conditions, or
    - objects to statutory endorsement on any specified ground.
- The department endorses (statutory endorsement) the risk-based work plan within 28 days of being told by a referral authority that it agrees with statutory endorsement.
- Tenement holder applies to the relevant council for a planning permit, and provides a copy of the permit to the department.
- The department approves the risk-based work plan within 28 days of the Tenement holder providing the planning permit to the department.
- Tenement holder gives seven days' notice to the department (Chief Inspector) before work commences.

Figure 1: Key steps in mining industry project approval



Part A – Steps before submitting a risk-based work plan using online RRAM

A.1 Introduction

Mining industry projects can be above ground and/or underground. They can involve many activities, use a variety of machines and equipment and takes years to complete.

Mining sites can be located in different locations, from remote regional locations to close proximity to residential properties. They could be near a waterway, intersect environmentally sensitive flora /faunal habitat, or be on a heritage site. This large number of variables creates a range of risks to onsite and offsite receptors.

> Purpose of the MRSDA:
> *The purpose of this Act is to encourage mineral exploration and economically viable mining and extractive industries which make the best use of, and extract the value from, resources in a way that is compatible with the economic, social and environmental objectives of the State.*

The risk-based work plan details the mining industry project. To meet the purpose of the MRSDA, the work plan must:

- *identify the risks that the work may pose to the environment, to any member of the public, or to land, property, or public infrastructure in the vicinity of the work; and*
- *specify what the licensee will do to eliminate or minimise those risks as far as reasonably practicable;*

The key to a successful mining industry project is early engagement by the Tenement holder with ERR, referral authorities and council. This engagement occurs initially at the site meeting and then through continued dialogue to resolve issues and information requirements.

> According to the MR(SD)(MI)R:
> ***mining hazard** means any mining activity and circumstance that may pose a risk to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of work carried out at a mine;*

The Tenement holder must collect information, and process it to facilitate an initial site meeting. That meeting will determine the information that will be required in the risk-based work plan.

Part A of the Guideline guides the Tenement holder on what information to research and compile to:

- facilitate the pre-work plan site meeting
- maximise the benefit of the site meeting
- prepare the risk-based work plan.

This part of the Guideline aims to streamline the background work that the Tenement holder would undertake. The collection and presentation of this background work in a structured way will benefit the Tenement holder, by identifying:

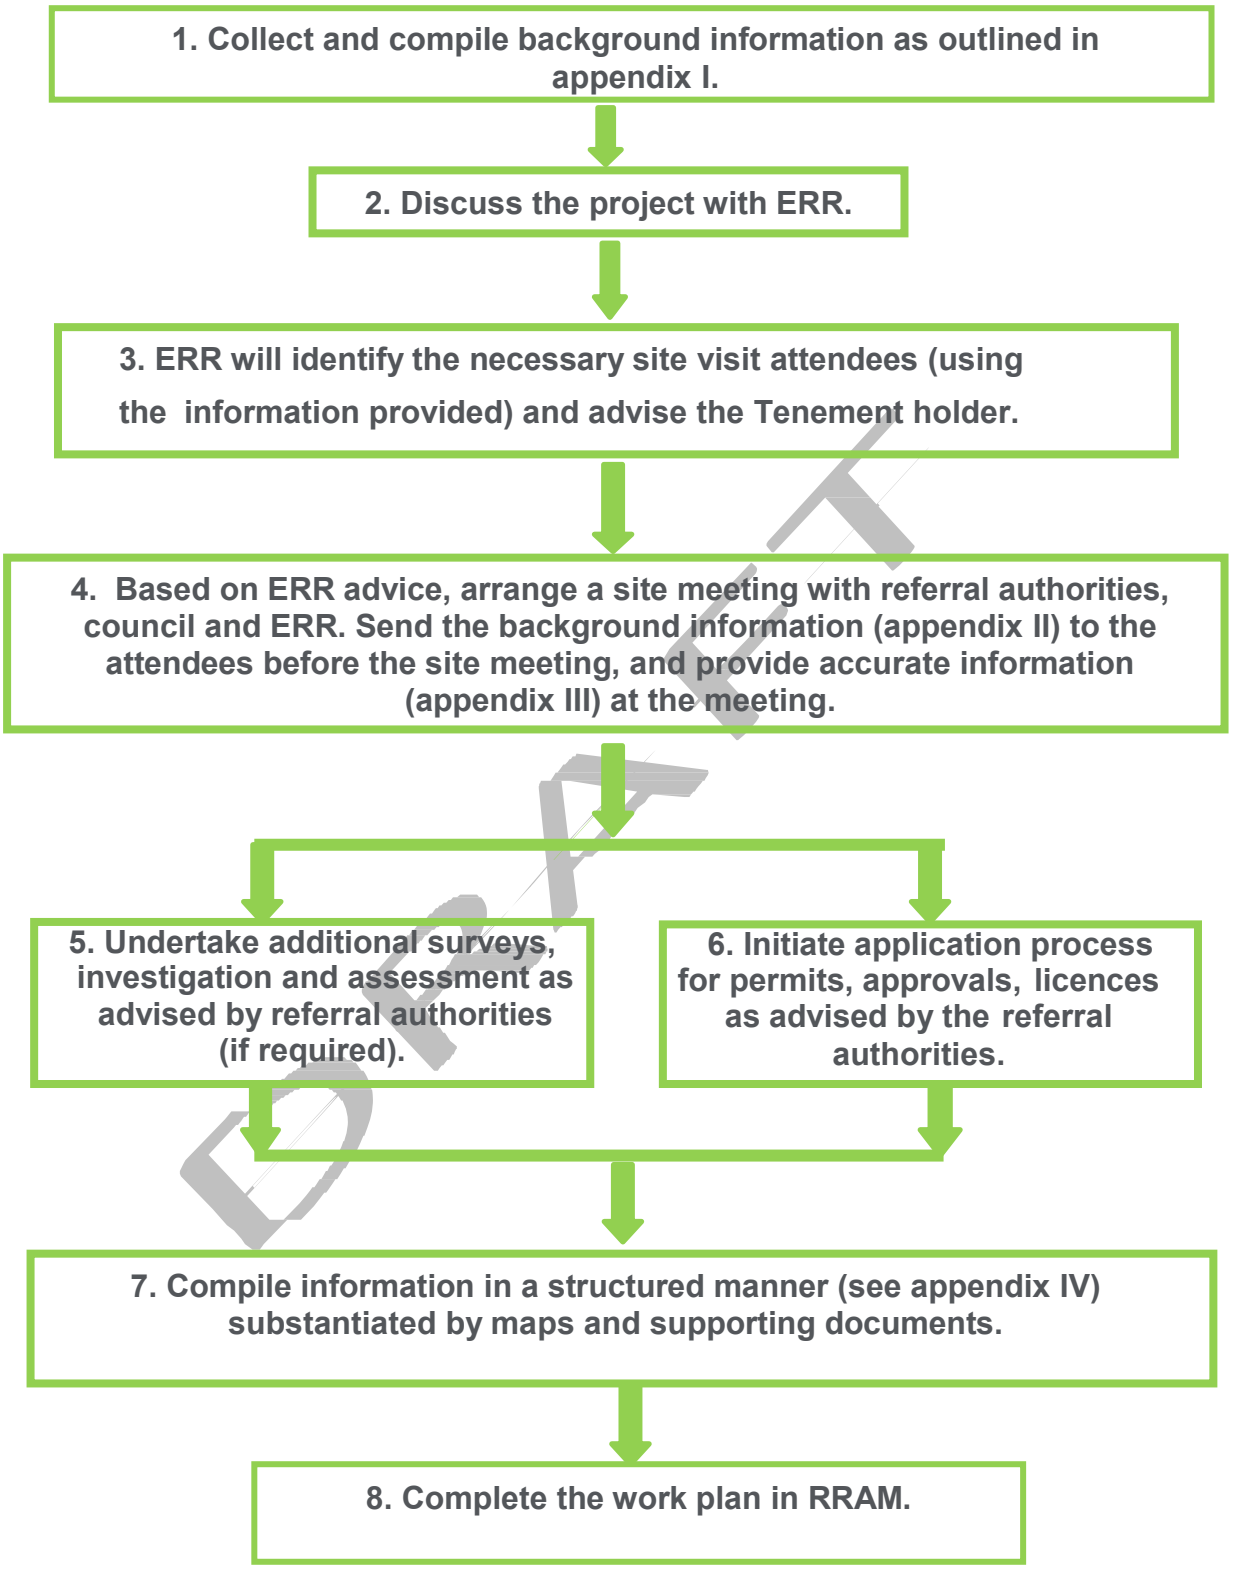
- any planning and environmental legislation that may affect the project
- any permits, approvals or licences that might be required before the project commences
- any requirement for additional environmental investigation, surveys and assessment to support the application and approval process
- how the Tenement holder can plan and progress several approval activities concurrently, thereby saving time and avoiding unnecessary project delays.

A.2 Steps before preparing the risk-based work plan online using RRAM

To achieve an effective outcome from the initial site meeting, the Tenement holder should follow these steps (**figure 2)**:

1. Collect and compile background information as outlined in appendix 1.
2. Discuss the project with ERR (see appendix 16 for contact details). ERR will identify the necessary site visit attendees and advise the Tenement holder.
3. Based on ERR advice, arrange a site meeting with referral authorities, the council and ERR.
4. Send the background information (appendix 2) to the attendees before the site meeting, and provide accurate information at the meeting. Appendix 3 lists possible questions that may be raised at the site meeting. Referral authorities may confirm or refute or clarify the background information used to develop the project.
5. Based on ERR, referral agency and council comment at the meeting, undertake additional surveys, investigations, or assessments (as required). Consult relevant referral authorities during this work so the surveys, investigations or assessments meet the referral authorities' requirements and objectives.
6. Progress with any application for required permits, licences or approvals, other than the MRSDA work plan and planning consent.
7. Compile information in a structured manner, substantiated by maps and supporting documents where necessary. Consider the risk assessment information included in appendix 4.
8. Go to part B to prepare and lodge the work plan online in RRAM.

Figure 2: Recommended steps before preparing the work plan

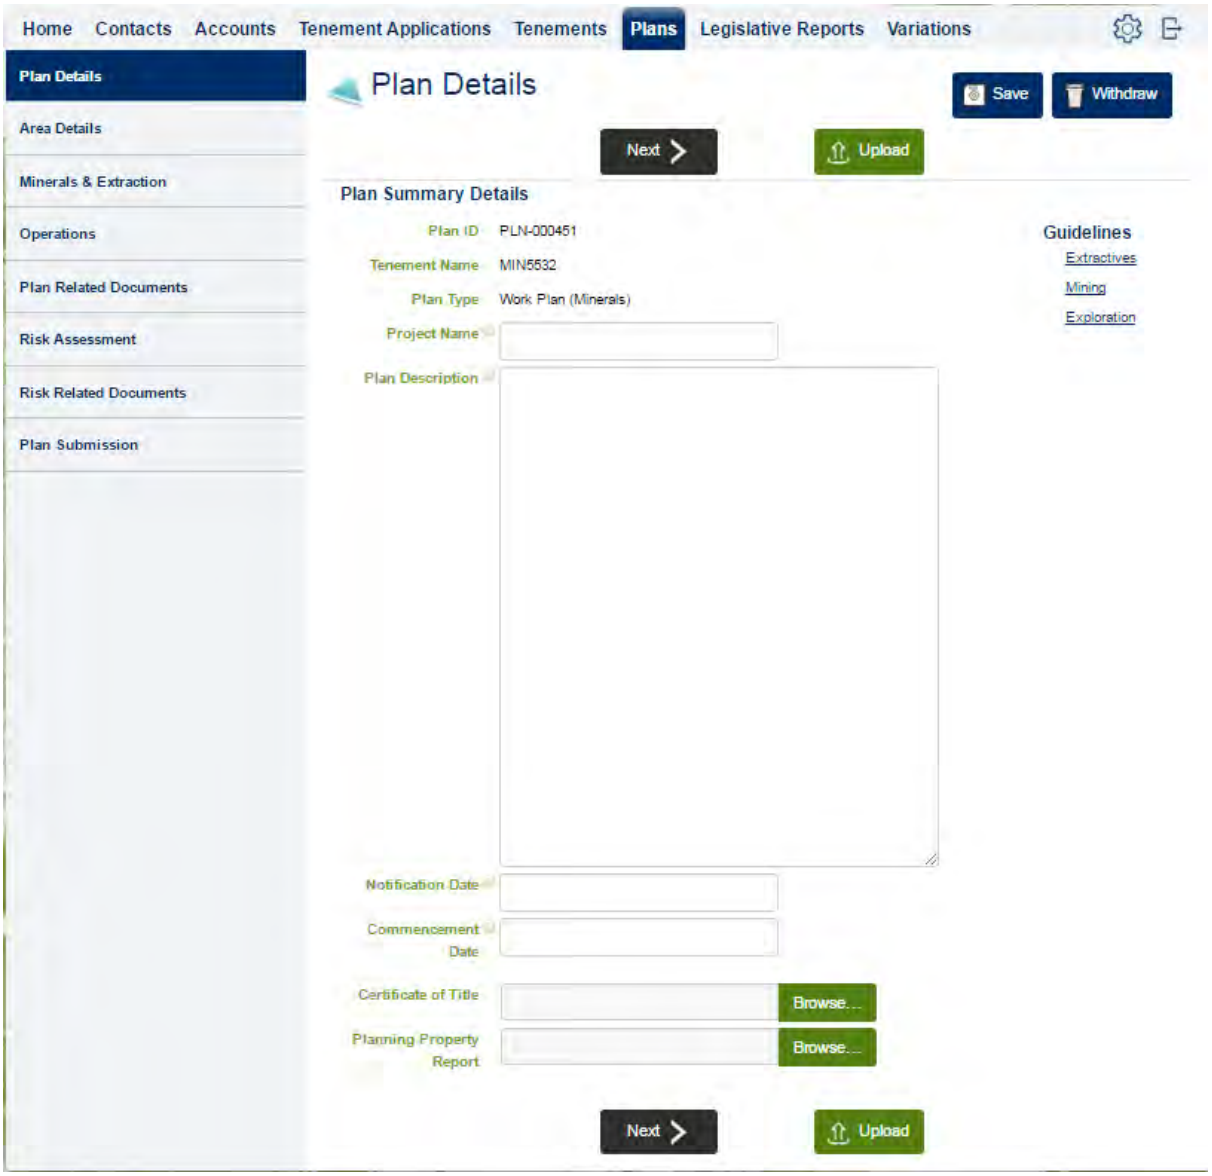


DRAFT

Part B – Preparing a risk-based work plan using RRAM

ERR's RRAM solution enables Tenement holders to complete risk-based work plans in accordance with the requirements of Schedule 15 of the MR(SD)(MI)R. The online form requires minimum targeted information that clearly identifies the risks that the proposed activity may pose to the environment, public safety, infrastructure and community, and how the Tenement holder proposes to eliminate or minimise the risk. It allows focus on key risks by priority.

Figure 3: Menu option in plans in RRAM



A risk-based work plan using RRAM contains three sections:

B.1. A high level description of the proposed exploration work

B.2 A risk assessment, including an assessment of the hazards relating to the activities, the receptors, consequences, controls, monitoring and reporting proposed

B.3 Attachments, including the site plans, a description of community consultation and rehabilitation

Initiating a work plan in RRAM

- Following contact with the department, ERR will create a new PLAN (work plan) in RRAM and change the author to the Tenement holder's nominated user.
- The Tenement holder accesses the PLAN through the RRAM business portal to prepare the risk-based work plan.

For a work plan variation, see part D.

B.1 Project description

B.1.1 Plan details

Fields or attachments in RRAM	Explanation
Project name	Provide the name of mining project – for example, 'Project Mineral Sand Mine'.
Work plan description	Provide a general description of the activities the risk-based work plan covers (include information for both above ground and underground work, under separate headings). For a new risk-based plan, information to be included in this section includes: MRSD(MI)R Schedule 15: ***"Part 1—Required information–mining work*** ***1 Description of work*** *1.2 A general description of geological information pertaining to the work, including stratigraphy, any adverse geological structures, the minerals to be extracted, and the estimated ore resources and reserves."* Description of geology, geological structure (faults, fractures etc.), current and past land uses (such as contaminated land, old tailing storage facilities, underground voids). MRSD(MI)R Schedule 15: **"*Part 1—Required information—mining work*** ***1 Description of work*** 1.3 *A general description of the mine operations that includes—* *(a) the method and scale of extraction; and* (b) *ore processing methods and facilities; and* *(c)waste disposal methods and facilities; and* *(d) stockpiling facilities; and* *Other mine infrastructure"* For an above ground mine, describe site layout and operations (as applicable): • Extraction methods and processing • Proposed area and depth of extraction, the proposed stages of extraction (if applicable) and the proposed design of the extraction pit, including the number of benches, the slope configuration (bench height, berm width), the terminal slope configuration • Location of water courses, proposed drainage diversions and water quality management; • Dewatering locations and methods. • Blasting methods, procedures and schedules • Location, dimensions, and design of dams and tailings ponds; • Location, dimensions and design of all waste dumps and soil stockpiles; • Vegetation and land management, particularly proposed clearing; • Mine rehabilitation and closure concept and planning • Permits, approvals and licences. • Specify the general location of topsoil, overburden and product. • Describe water sources for site operation (groundwater, dam etc.). • Describe the physical and chemical composition of quarry waste materials, identifying potential hazardous substances, including the presence of sulphides (if acid sulphate soil has been excavated and/or chemicals used in processing). In addition to the information above, information required for an underground mine includes: • access, the ventilation system • the extraction system • the stope and pillar layout; the stope or mining sequence • ore handling and transportation

Fields or attachments in RRAM	Explanation
	• the mine site layout and services. • Any backfilling methods/systems • The footprint at the surface of the underground mining operations MRSD(MI)R Schedule 15: "***Part 1—Required information—mining work 1 Description of work*** *1.5 A description of sensitive receptors (including their location) in relation to the environment, any member of the public, or land, property or infrastructure in the vicinity of the work."* • Description and location plan of roads, bridges, pipelines, power lines, easements, reserves, waterways, depth to groundwater, heritage sites and communities in the vicinity of the project area. MRSD(MI)R Schedule 15: ***"Part 1—Required information—mining work*** ***1 Description of work*** *1.1 A location map of the work plan area and surrounding areas, drawn at an appropriate scale proposed, that shows the following—* *the extent and status of Crown lands and private lands;* *residential, commercial and industrial development;* *public facilities and infrastructure;* *rivers and streams within the work plan area and within 2 km of the work plan area."* MRSD(MI)R Schedule 15: ***Part 1—Required information—mining work*** ***1 Description of work*** *1.4 A site map, drawn at an appropriate scale, showing the general layout of the mine and associated facilities and infrastructure.* • Show relevant information on a regional area map (see **table 1** for information to be included on a regional area map). • Show relevant information on a site layout plan (see **table 1** for information to be included on a site layout plan). Note: • See **appendix 5** for guidance on sensitive receptors in the vicinity of the work. • If there are sensitive receptors located within the generic GRZ (nominally=4H), attach a **Preliminary Slope Instability Impact Assessment** to the work plan. See **appendix 10** for the content of a Preliminary Slope Instability Impact Assessment. • In the case of a work plan variation, it should include how the variation relates to previously approved work plans (and variations) (see **part D** of this guideline).
Attachments	Planning property report (see **part a** and **appendix 1**)

B.1.2 Area details

Fields or attachments in RRAM	Explanation
Property name	Provide where applicable
Address	Provide property address of the project area. This is the physical address of the site. If street or rural road numbers are not used, refer to the nearest road.
Suburb / town	Provide suburb/town of the area.
Postcode	Provide postcode of the area.

Area size

Fields or attachments in RRAM	Explanation
Area (hectares)	Provide the size of the mining licence area.

Land tenure (ownership) details

Fields or attachments in RRAM	Explanation
Land tenure type	Select type of land tenure that applies to the tenement area.
Depth limitations	
Depth limit	

B.1.3 Minerals and extraction

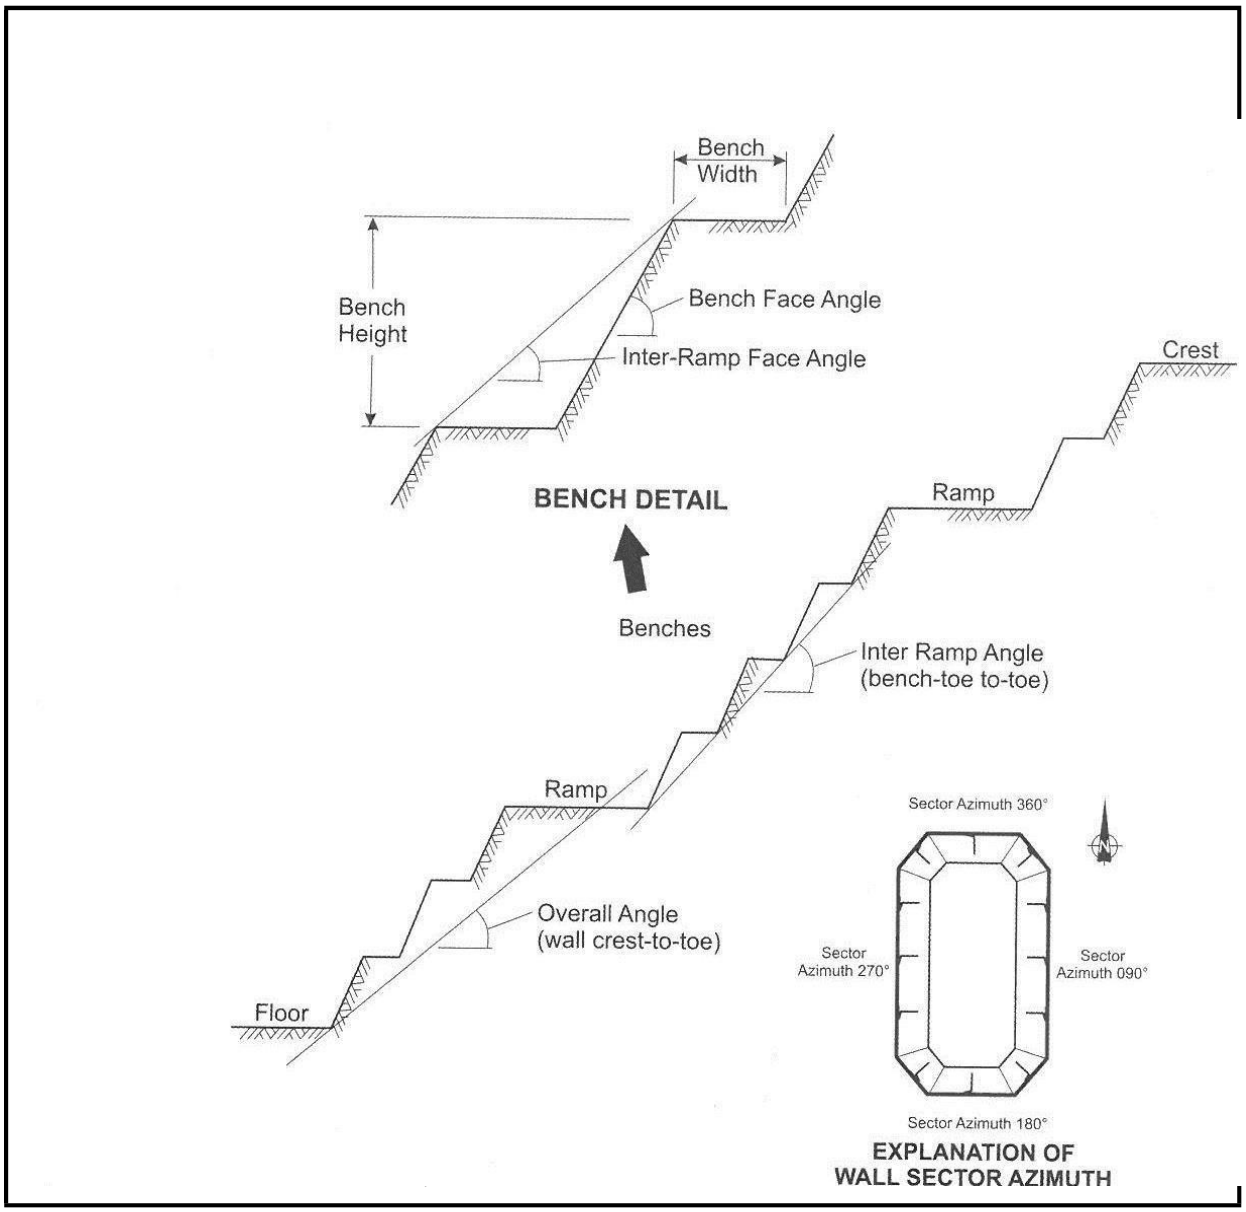
Resource type

Fields or Attachments in RRAM	Explanation
Commodity to which the work plan pertains	Select all commodity types to be extracted from the dropdown list. The selection must be the same as what appears on the licence. If more than one resource is selected, the primary resource must be indicated.
Commodity, primary	Indicate the principle commodity to be mined.
Total resource estimate	Provide the total resource estimate of the mineral resources. Note: This information in not available in the printed version of the risk- based work plan: you need to send the information to referral authorities and council.
Unit of measure	Select the unit of measure relevant to the estimate of the total resource provided.

Proposed final depth of extraction

Fields or attachments in RRAM	Explanation
Estimated maximum terminal depth	Give the maximum proposed vertical distance between the toe and crest of the terminal (final, overall) slopes of the pit before any rehabilitation. Include relevant information for an underground mine.
Batter slope angle	Provide the average horizontal angle of the terminal batter slopes of the pit before any rehabilitation, expressed in degrees (e.g. 15, 30, 45, 90). See the overall angle in figure 4. If operational batters differ from terminal batters provide details ot both. If rehabilitation is not undertaken within a reasonable time frame, the terminal batter slope must demonstrate that the slope will be safe and stable for the period of exposure. . You must detail the final rehabilitation slope in the rehabilitation plan. See figure 4.

Figure 4. Schematic description of batter design for open pit



Top soil, overburden and subsoil disturbance

Fields or attachments in RRAM	Explanation
Estimated depth of topsoil	Provide the estimated depth of topsoil to be disturbed (average across the extraction area).
Estimated volume of subsoil	Provide the estimated volume of subsoil to be disturbed. Subsoil is the layer of soil below the top soil. It is typically made up of sand, silt and/or clay, but lacks the organic matter and humus found in the topsoil. Subsoils can usually be used for rehabilitation purposes.
Unit of measure – subsoil	Select the unit of measure relevant to the estimate provided.
Estimated depth of subsoil	Provide the estimated depth of subsoil to be disturbed (metres), averaged across the mining area.
Estimated volume of overburden	Provide the estimated volume of overburden to be disturbed. Overburden is the soil and rock that is removed to gain access to the resource in a pit. It is usually piled on the surface at the site at designated areas where it will not impede expansion of the mine operation. It is used for the progressive and final rehabilitation of the site.
Unit of measure – overburden	Select the unit of measure relevant to the estimate provided.
Estimated depth of overburden	Provide the estimated depth of overburden (metres), averaged across the pit.
Area of disturbance	Provide the area of disturbance (square metres) relating to the surface area. The extent of disturbance should consider set-up/construction and operation/production activities, including the construction of roads, plant, pits, stockpiles, waste dumps and dams. This information to be depicted on the site area plan (see table 1).
Maximum disturbance at any time	Provide an estimate of the maximum area of disturbance (open area) in hectares at any given time. This estimate does not include any area undergoing progressive rehabilitation.

B.1.4 Operations

Operation type

Fields or attachments in RRAM	Explanation
Operation type	Specify the operation type(s) proposed for the site from the dropdown menu. Options include: • *Hard rock open pit*– Applicable to materials with high strength and/or abrasive materials such as granite or basalt, using surface techniques from an open pit • *Doze/excavate and detect* – Surface stripping with mechanical equipment, followed by intense hand-held detection techniques to extract the resource • *Shallow excavation* (depth must be less than 5 metres) – A surface technique for shallow deposits, which are typically softer materials such as sands • *Open pit* – Applicable to unconsolidated materials where extraction uses surface mining techniques. • *Dredging* – Use of a natural or human-made body of water overlying the deposit. Use of a variety of surface equipment, including bucket-wheel suction or a cutter-head with suction that can be used to extract the resource.
Operation type – other	Include any relevant operation type not included in the dropdown list.

Plant, equipment and method

Fields or attachments in RRAM	Explanation
Plant and equipment description	Provide a general description of operational equipment to be used on site, including but not limited to, equipment for extraction, processing, haulage. Describe (and show on the site layout plan) the location of processes or equipment (such as processing plants next to an open pit) that may heighten the potential for slope instability. Describe equipment to be used for dewatering (if applicable). Describe the number and location of any water bores and pumps. Show on a plan the location of: • workshops • storage sheds • lunchroom • the amenities block • the site office • the weighbridge • laboratory testing • training and meeting rooms • the maintenance hardstand and vehicle wash-down.

Operating hours

Fields or attachments in RRAM	Explanation		
	Operations	Sales	Processing
Monday to Friday – Start	Enter in 24 hour format, in half hour increments. Proposed hours for different business processes – for example, operations, sales, processing and maintenance should be entered separately.		
Monday to Friday – End			
Saturday – Start			
Saturday – End			
Sunday – Start			
Sunday – End			
Public holiday activity			

B.1.5 Attachments to risk-based work plan

Attach the following documents online. All maps and documents should be legible.

Table 1: Requirements of the regional plan, work plan and site layout plan areas

Fields or attachments in RRAM	Explanation
Work plan area (Location Map as per Regulation)	Work plan area maps clearly identify the location of the proposed mining activities. The maps should be of sufficient detail to enable the on-the-ground location of a work site. The amount of information on the work plan area map will depend on the complexity of the work plan area (for example, the variation of land types and vegetation across the regional plan area). **Requirements in risk-based work plan area** • Map prepared on a scale of 1:25,000 or at an appropriate scale for showing sensitive receptors within 2 kilometres of the surface footprint of the Tenement area. At a minimum, natural and human-made sensitive receptors within the Geotechnical Risk Zone (GRZ) area must be shown (see http://www.energyandresources.vic.gov.au/earth-resources/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/guidance-material-for-the-assessment-of-geotechnical-risks-in-open-pit-mines-and-quarries). GRZ applies to the surface footprint of the Tenement area. • North direction, legend, scale, date of and revision date of drawing • The extent of Crown lands, private lands and private land allotments for the proposed work plan area • Location of possible occupied houses, community facilities • Location of townships, cadastral boundaries • Location of waterways, parks and reserves, and environmental overlays (as included in the planning property report) • Radius of circles (at minimum 500 metres, 1 kilometre, 2 kilometres) from the surface footprint of the Tenement area • Maximum area of disturbance (provide separately for above ground and underground • Location of infrastructure, including major and minor roads (with names), bridges, rail lines, pipelines (water, gas, telecommunication), power lines, easements Note: See appendix 4.1 for guidance on sensitive receptors in the vicinity of the work. If there are sensitive receptors located within the GRZ (nominally=4H), attach a **Preliminary Slope Instability Impact Assessment** to the work plan. See appendix 10 for the content of a Preliminary Slope Instability Impact Assessment.
Regional plan area	**The regional location map is required to illustrate where the work plan area maps are located in relation to the licence boundary.** **Requirements in regional plan area** • Location of work authority area at a scale of 1:100,000 or 1:50,000 • Radius circles (at minimum 1 kilometre, 2 kilometres, 5 kilometres and 10 kilometres) from work authority boundary • Roads (including names), townships / built-up areas, l ocation of the mining area (proposed disturbed area), boundaries of the Tenement and risk-based work plan with distances and bearings • North direction, legend, scale, drawing and revision date *Note*: Please provide the map in an A3 size format and ensure it is legible.

Fields or attachments in RRAM	Explanation
Site layout plan area (site map as per regulation)	**A site layout plan area is required to illustrate the general layout of the plant-associated facilities and infrastructure.** **Requirements in site layout plan area** • A scale of 1:1,000, 1:2,500 or other appropriate scale, including North direction, legend, scale, date of and revision date of drawing • Mining licence boundaries, extraction boundaries (including underground), buffers and depth limitations • Cadastral boundaries • Cross-sections, showing geology, extraction and terminal batter design with proposed bench heights, berm details and working batters for all parts of the mining area • Existing surface contours, topographical features, drainage patterns, water courses and vegetation to be removed / retained • Plant and equipment (buildings and surface facilities, location of power generation and/or reticulation, offices and toilets) • Anticipated extent of open cut extraction • Sequence of open cut extraction (if applicable) • Proposals for landscaping of the surface footprint area, including buffer zones and retained areas of native vegetation • Adjoining public road(s) (including names) • A survey benchmark with a reduced level • Location of access roads • Location of water dams and storage, in-pit sumps, tailings storage and tailngs pipe lines • Location of onsite power lines, gas lines and any other easements • General location of stockpiles for topsoil, overburden, waste rock, and ROM product • Location of fuel storage areas – aboveground storage tank (AST), underground storage tank (UST) • Location of explosives, additives or hazardous waste storage areas • Location of water bores and pumps (if any) • Location and design of drainage diversion, including levees

B.2 Risk assessment

In this section of the risk-based work plan, the mining industry Tenement holder must identify mining hazards and assess risk in accordance with the requirement of Schedule 15 of the MRSD(MI)R.

Risk assessment is the process of finding, recognising and describing the mining hazard(s) within the work plan area, a clear pathway to one or more receptor(s), and the potential impact(s) on the receptor(s) if the hazard occurs.

> The MRSD(MI)R stipulates
> *"**mining hazard** means any mining activity and circumstances that may pose a risk to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of work carried out at a mine."*

Based on the possible questions raised at the site meeting (a**ppendix 3**), the Tenement holder should be able to identify the hazards, receptors and potential consequences for this section of the risk-based work plan.

A risk is not present if:

- the mining hazard does not exist within the work plan area, and/or
- there are no receptors that could be impacted.

The Tenement holder will:

- undertake a risk assessment by identifying the risks that the activities may pose to the environment, to any member of the public, or to land or property in the vicinity of the activities. This involves identifying hazards located within the tenement area and assessing the potential consequences of the hazard on public safety, the environment, public infrastructure, private infrastructure and community facilities (the receptors). Receptors may be located inside (for example, an historical heritage artefact) or outside the tenement boundary (for example, lakes, waterways, public roads, fauna), and could be adversely impacted if the impact of the hazard is not effectively controlled. See **section B.2.1**.
- specify what the Tenement holder will do to eliminate or minimise those risks **as far as reasonably practicable.** This specification involves proposing the controls that the Tenement holder will implement to remove, minimise and control the hazard and possible consequences. The objective of the control is to comply with the standards and thresholds set out in regulations, policies, guidelines and leading practice references. By focusing on the objectives/ outcomes to be achieved (based on the proportionality of the risk), the Tenement holder should demonstrate how the risk will be managed. See **section B.2.2**.

A risk assessment should be undertaken:

- for each phase of the project – set-up, construction, operation, production, rehabilitation and closure
- for combinations of all hazards, risk sources and receptors at risk (e.g. a single hazard may be associated with multiple risk sources and multiple receptors).

B.2.1 Risk 1

Fields or attachments in RRAM	Explanation
B.2.1a Risk hazard	Select the relevant identified hazard from the dropdown list. See **appendix 4** for a list of potential hazards. MRSD(MI)R Schedule 15: ***"Part 1—Required information—mining work*** ***2 Identification of mining hazards*** *2.1 An identification of mining hazards that may arise from each phase of the work, including set up/construction, operations/production and rehabilitation/closure."*
B.2.1b Risk source	Select from the dropdown list one or more potential sources of risk specific to the hazard identified. See **appendix 4** for a list of potential risk sources.
B.2.1c At risk	Select from the dropdown list what is at risk from the risk source if a standard control or additional control fails. See **appendix 4** for a list of potential 'at risk' features. MRSD(MI)R Schedule 15: ***"Part 1—Required information—mining work*** ***3 Identification and assessment of risk*** *3.1 An identification and assessment of the risks that the identified mining hazards may pose to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work."*

B.2.2 Risk management plan

A risk management plan is required under Clause 4, Schedule 15 of the MRSD(MI)R. The Tenement holder can meet the requirements of a risk management plan by completing the RRAM fields outlined in sections **B.2.2a** to **B.2.5**.

The extent of potential impacts depends on the controls that the Tenement holder implements. Control is defined as '*a system, process, procedure, equipment or other organisational capacity that prevents the consequences of the risk from occurring*'[1]

A standard control is considered to be accepted practice in the mining industry for addressing a potential impact on a sensitive receptor. Standard controls are recognised procedures, guidelines, methods, and codes of practice that can be sourced from regulations, policies, guidelines and leading practice references.

Standard controls can include:

- *Engineering/physical controls* – controls built into the physical design of plant or equipment, which do not rely on people to operate effectively. Examples include the substitution of a hazard with something less hazardous, such as using a less toxic chemical or an engineered control such as a pressure relief valve.
- *System-based controls* – part of a defined management system, which rely on staff to be implemented. Implementation is prescribed through rules, protocols and management reviews. An example is an Environmental Management System that features a range of policies, plans, procedures, roles and responsibilities to identify, plan, implement, monitor, evaluate and report on the effectiveness of controls to achieve environmental targets and objectives.
- *Procedural-based controls* – a written set of rules or guidelines, which rely on staff to be implemented. Staff implementing these controls need to be appropriately trained, assessed and monitored to maintain the required level of competency / performance.
- *Staff-based controls (least effective)* – controls that require people to identify, assess and respond to issues appropriately based on their skills, knowledge and experience.

Engineering and system controls are considered to provide a higher level of risk management than procedures or staff-based methods.

B.2.2a Standard controls and possible consequences

Fields or attachments in RRAM	Explanation

[1] Department of Resources, Energy and Tourism 2008

Fields or attachments in RRAM	Explanation
Standard control	List the standard controls identified to mitigate or lessen the risk. See **appendix 6** for a list of suggested standard controls. The Tenement holder should identify standard controls that will apply standards and thresholds set out in regulations, policies, guidelines and leading practice references. For example, they must demonstrate that the identified standard control will meet the noise threshold in SEPP N-1 or the ground vibration limit at the receptor. If the standard control is documented in a management plan (a blast management plan, for example) that is attached to the work plan, state it here. MRSD(MI)R Schedule 15: ***Part 1—Required information—mining work*** ***4 Risk management plan*** *4.1 A risk management plan that—* *(a) specifies the control measures to eliminate or minimise, as far as reasonably practicable, the identified risks associated with mining hazards; and* *(b) specifies the objectives, standards or acceptance criteria that each control measure or a combination of control measures will achieve;*
Possible consequence	Provide a brief description of the potential impacts remaining after the standard control has been implemented. Potential residual impacts relate to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work. *Example*: *Noise level will remain below SEPP N-1 threshold at two residential properties 400 metres south east from the WA boundary.*

B.2.2b Consequence and likelihood rating

MRSD(MI)R Schedule 15:

Part 1—Required information—mining work 3 Identification and assessment of risk

3.2 For the purposes of item 3.1, an assessment of a risk posed by a mining hazard must have regard to—

(a) the nature of the mining hazard; and

(b) the likelihood of the mining hazard causing, or contributing to, any harm or damage to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work; and

(c) the severity or consequence of the harm or damage that may be caused.

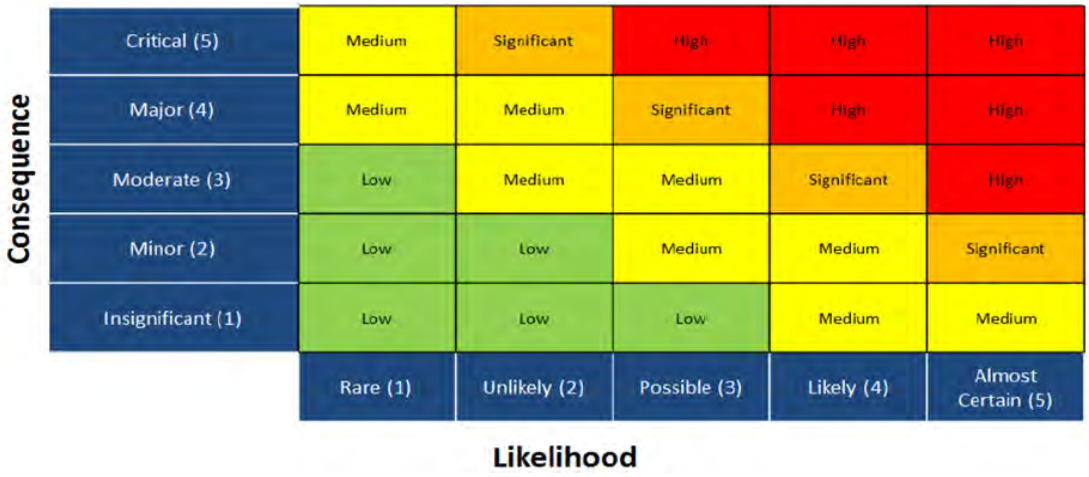
Fields or attachments in RRAM	Explanation
Consequence rating	Select the consequence rating from the dropdown list: • Insignificant • Minor • Moderate • Major • Critical This is the rating after accounting for the existence and effectiveness of the standard controls defined in B.2.2a. Base the consequence rating on reasonable judgement of the retained consequence described above. See **appendix 7.**

Fields or attachments in RRAM	Explanation
Likelihood rating	Select the likelihood rating from the dropdown list: • Almost certain • Likely • Possible • Unlikely • Rare This is the rating after accounting for the existence and effectiveness of the standard controls defined in B.2.2a. Base the likelihood rating on reasonable judgement of the likelihood described above. See **appendix 8**.

B.2.2c Risk rating

Fields or attachments in RRAM	Explanation
Risk rating	The risk rating is automatically calculated for each hazard type based on the selected consequence and likelihood ratings in B.2.2b. (Consequence and likelihood are applied after the implementation of standard control for that hazard.) RRAM calculates the following risk ratings: • Low • Medium • Significant • High

Figure 5: Risk matrix



B.2.2d Risk monitoring and reporting

MRSD(MI)R Schedule 15:

"Part 1—Required information—mining work

4 Risk management plan

4.1 A risk management plan that—

includes a monitoring program to measure performance against all the specified objectives, standards and acceptance criteria; and

specifies arrangements for reporting on performance against all the specified objectives, standards and acceptance criteria."

Fields or attachments in RRAM	Explanation
Risk monitoring and reporting	A risk rating of 'medium' and 'low' will require the monitoring of the identified standard controls, to ensure they remain effective. Describe the approach for monitoring whether the identified standard control is achieving the objectives/ outcomes specified in B.2.2a. Consider linking the monitoring to the overall site monitoring and Emergency Management Plans. • Describe the approach to monitoring in this section of RRAM (or as a separate attachment). Outline the monitoring method, location plan, key parameters to be monitored, trigger levels for key parameters, equipment to be used, the frequency of monitoring, and the capacity of the person undertaking monitoring. • Describe what mitigation measures or actions are to be taken should a threshold (trigger) level be exceeded. For example, what action will be taken should a certain amount of movement (as measured by eg. pins or prisms) be exceeded over a certain time period. Include the planned review of the monitoring program (for example, criteria for review, who, when and how). Describe how the information collected will be reviewed to consider control effectiveness. • Describe the approach to reporting in this section of RRAM. Outline reporting to whom (for example, the ERC), the frequency of reporting, reporting parameters, the format of reports (text, graphs, tables, cross sections), the presentation of reports (for example, trends, against standard/thresholds, trigger levels), mitigation/ measures where trigger levels are exceeded. It must also include the review process of the monitoring reports (for example, who reviews the report and makes the decision).

B.2.2e Additional control in risk treatment plan

The licensee is responsible for demonstrating that the standard control(s) specified under section B.2.2a are effective in achieving the objective/outcome (standards or thresholds) required under the applicable legislation, policies, guidelines or leading practice references.

If an objective/outcome cannot be met, the Tenement holder should review the consequence and likelihood ratings (under section B.2.2b) and re-assess the risk rating. **Appendix 9** provides acceptable risk ratings for various instances of consequences. The Tenement holder should discuss acceptable risk ratings with ERR and relevant agencies.

If the risk rating is 'significant' or 'high' (originally or after a review of risk assessment), then the standard control is considered to be not effective in meeting the objective/ outcome, and the Tenement holder must implement additional treatment (control) to mitigate the risk. The licensee is required to attach the risk management plan (see section **B.3**) to RRAM, outlining the additional mitigation measure(s) that the Tenement holder will implement to mitigate the significant or high risk(s).

Suggested contents of a risk management plan (see appendix 11 for examples)

- Relevant control design specification
- Documentation on the control's objectives and limitations
- Control monitoring and reporting program, including:
- an overview of the management process to monitor and report the control's performance
- the proposed monitoring and reporting program for the control and activity
- The qualifications of the personnel responsible for the design, implementation and operation of the control
- Relevant peer review reports on the control's effectiveness in comparable operations and environments
- Peer review reports on the control's design specification
- Modelling and simulation report(s)
- Documentation describing any proposed testing and observation of the control during operation

B.2.2f Add another risk

After completing the risk assessment for risk 1, the Tenement holder needs to select in RRAM 'Add another risk' and complete the iteration in RRAM as outlined in sections B.2.1a–B.2.2d (and B.2.2f if applicable) until all the hazards relating to the proposed project are captured in the risk-based work plan in RRAM.

B.3 Attachments – documents related to the work plan

Fields or attachments in RRAM	Explanation
Risk management plans	Attach a risk management plan for each hazard type if the risk rating is significant or high. See **appendix 11**.
Community engagement plan	Attach a community engagement plan. See **appendix 13**.
Rehabilitation plan	Attach a rehabilitation plan. See **appendix 14**.

Plan submission

After completing B.1 to B.3 in RRAM, the Tenement holder should select to submit the risk-based work plan for assessment. A payment request will be prompted at this stage. Consult with ERR about the correct fee for your work plan.

While RRAM checks for the completeness of mandatory fields in PLAN, the onus is on the licensee to ensure the completeness of the work plan before it is submitted.

Part C – Work plan assessment and approval

Risk-based work plans will be assessed as follows:

1. The department assesses the risk-based work plan within 28 days of receipt.
2. The department **accepts** the work plan as being satisfactorily compliant with the MRSD(MI)R for referral to referral authorities (if required).
3. The department forwards the work plan to referral authorities (within 28 days of receipt) as part of a statutory and/or non-statutory referral process (see **appendix 15** for the referral authorities).
4. ERR will send to the referral authority (for comment) a printable version of the risk-based work plan that the Tenement holder lodged in RRAM

According to MRSDA Section 40A:

(1) On receiving a work plan, the Department Head must, within 28 days, give a copy of the work plan or variation to an approved work plan to every referral authority that the Department Head considers, having regard to the kind of work proposed under the work plan or variation, should be given the work plan or variation.

(2) Before complying with subsection (1), the Department Head must be satisfied that the work plan or the variation to an approved work plan complies with the regulations.

5. The department statutorily endorses (under s40(4) of the MRSDA) the printable copy of the risk-based work plan, after the referral authorities confirm they have no objection to the plan's statutory endorsement.
6. ERR provides the endorsed printable risk-based work plan and the draft work authority conditions (including any condition imposed by referral authorities) to the Tenement holder so they can submit the plan and conditions to the council with the planning permit application.

According to Victorian Planning Provision Clause 52.08-2 Mineral extraction:

An application to use and develop land for mineral extraction must be accompanied by:

- *A copy of a work plan or a variation to an approved work plan that has **received statutory endorsement** under section 77TD of the Mineral Resources (Sustainable Development) Act 1990.*

7. The department approves the printable statutorily endorsed work plan after the Tenement holder provides a copy of the planning permit to the department.

Part D – Work plan variation or work plan notification

Under the MRSD(MI)R, the Tenement holder can take either of the two pathways through RRAM:

- pathway for acceptance of a work plan notification not legislated in the MRSDA, or
- pathway for approval of a work plan variation in accordance with s41 of the MRSDA.

The decision to follow the notification or variation pathway is based on whether the proposed changes to the work will **significantly increase the risk**.

Important information about significant increase in risk as stipulated in the MRSDA

- RRAM identifies four risk ratings: low, medium, significant, high (see section B.2.2c).
- A risk is considered significant when it falls in the category of significant and high.
- The Tenement holder can take the pathway of the work plan notification approval process (not a regulatory approval) when the proposed changes to work will not pose a risk that has a significant or high risk rating following the application of standard controls.
- The Tenement holder must make reasonable decisions about the risk assessment for their proposed new work.
- The onus is on the Tenement holder to demonstrate that the proposed new work will not constitute a significant risk.
- Se section D.2 of this guideline for more details.

The purpose of the notification is to allow ERR to assess the proposed changes and confirm whether a variation is required. This section provides guidance on how to assess whether a variation will likely be required.

The Tenement holder should consult with ERR whether a notification or a variation is required.

D.1 Work plan notification

A Tenement holder may seek acceptance of a work plan notification if the proposed new work retains a low / medium risk rating, or reduces the risk rating to medium / low when standard controls are applied, or eliminates the hazard. A Tenement holder must have an approved risk-based work plan to request acceptance of a notification.

A work plan notification may apply when:

- the Tenement holder/operator's details, address or land use change
- a change in resource, mining method, end use of site, hazards and/or sensitive receptors requiring only standard controls has:
  - not altered an existing low to medium risk rating that required only standard controls (for example, current standard controls remain effective for the proposed new work)
  - resulted in an existing low to medium rated risk that required only standard controls being eliminated (the risk no longer exists) or reduced. In this circumstance, the Tenement h older will notify ERR that approved standard controls are being ceased or changed.
  - resulted in a new risk being identified that requires only standard controls, and that has a risk rating of low to medium after the application of standard controls
  - the proposed new work does not require referral authority comment
  - reduced the risk rating from medium or low.
  - The proposed new work does not require planning permit amendment or Referral Authority comment

Examples of proposed new work that could represent an approved risk-based work plan notification

- Amending the staging of mining when the mining is entirely within the approved limit of the work plan
- Changing extraction methods
- Increasing the distance from neighbouring properties
- Reducing noise by enclosing the processing plant
- Reducing noise by switching from onsite power generation to mains power
- Using a new piece of equipment (that generates substantially less noise) to replace an existing piece of equipment
- Reducing dust by changing the mine access routes, increasing the distance to sensitive receptors
- Finding the mining area is no longer, or is significantly less likely to be, susceptible to flooding due to a sustained dry period

D.1.1 Steps for a work plan notification

The Tenement holder should take the following steps for work plan notification, and for the commencement of work relating to the notification:

- Assess that the proposed new works constitute a notification.
- Discuss with ERR that the proposed new work will be a notification.
- Confirm that the proposed new work will not require referral to referral authorities.
- Provide a formal notification to ERR, describing:
  a. the proposed new work in detail
  b. a risk assessment with supporting information (as stipulated under sections **2.1** to **2.2d** of this guideline)
  c. whether a risk rating remains unchanged, with reasons
  d. whether a risk rating has been eliminated, with explanation
  e. whether a risk rating has reduced (from medium to low), with reasons
  f. supporting map(s).

Important information about the approval of a work plan notification

- It is not a regulatory approval.
- It is the responsibility of the Tenement holder to ensure the proposed new work meets the criteria of notification described in this guideline at all times and throughout the operational period of the proposed new work.
- ERR will monitor whether the proposed new work accepted under the work plan notification meets the criteria of notification circumstances at all times.
- If the proposed new work no longer meets the notification criteria, ERR shall request that the Tenement holder lodges an application for variation in accordance with s41AA of the MRSDA.

D.2 Work plan variation

A Tenement holder should seek a variation to an approved work plan – in accordance with s41AA of the MRSDA – if the proposed new work involves:

- changes to mining methods
- a significant increase in risk, which requires an updated risk management plan (section **B.2.2** in this guideline)
- changes to the end of use of the mining area, which requires an update to the rehabilitation plan
- the identification of new hazards and sensitive receptors, requiring standard and additional controls
- changes to or lodgement (if previously not prepared) of a community engagement plan
- a new risk being identified that requires both standard and additional controls. The Tenement holder has to seek work plan variation approval for the proposed standard and additional controls.

Examples of proposed new work requiring a variation to an approved work plan and ERR approval, in accordance with s41AAB and Part 6B of the MRSDA:

- Discovery of a new species not previously listed
- The move of an existing listed species into a disturbed area
- Change in the direction of extraction, which moves it closer to sensitive receptors
- Inclusion of blasting as a new activity
- Change in extraction area
- Change in extraction methods, moving from dry extraction to wet extraction
- Change in processing method (for example, wash plant processing)
- Change in water storage, waste dump design, tailings storage facility
- Discovery of archaeological sites (deposits, features or artefacts)
- Removal of native vegetation. The removal, destruction or lopping of native vegetation is proposed, and an assessment is required under Victoria's Native Vegetation Permitted Clearing Regulations, with requirements determined by the relevant location category.
- Proposed new work requiring assessment or approval under other legislation. Other legislation could include but is not limited to:
  - *Aboriginal Heritage Act 2006*
  - *Crown Land (Reserves) Act 1978*
  - *Environment Effects Act 1978* (or consideration under s77T of the *Mineral Resources (Sustainable Development) Act 1990)*
  - *Environment Protection and Biodiversity Conservation Act 1999* (Commonwealth)
  - *Environment Protection Act 1970*
  - *Flora and Fauna Guarantee Act 1988*
  - *Heritage Act 1995*
  - *Land Act 1958*
  - *Planning and Environment Act 1987*
  - *Native Title Act 1993* (Commonwealth)
  - *Water Act 1989*
  - *Wildlife Act 1975*

D.2.1 Steps for a work plan variation

Preparation of a risk-based work plan variation in RRAM involves the same steps as a new risk-based work plan in RRAM (see p**art B** of this guideline) except the Tenement holder will complete only the sections in RRAM that are to be varied.

Important information about preparing a work plan variation in RRAM for the first time

The Tenement holder should complete a full risk-based work plan (the original approved work plan) in RRAM as if it is a new work plan, by completing all the sections in part B of this guideline.

A work plan variation through RRAM involves the following steps:

- The Tenement holder should consult with ERR about the proposed new work that requires a work plan variation.
- ERR prepares a clone of the existing work plan in RRAM (identifying the clone as a variation).
- The Tenement holder varies the sections of the cloned work plan in RRAM that apply to the proposed changes to work.
- The Tenement holder completes the full work flow process in RRAM from B.1 to B.3, and submits the work plan variation in RRAM.
- ERR approves the work plan variation by following the process in 'Work plan assessment and approval' in this Guideline.

Part E – Who is affected by the new regulation requirement?

All new work plans and variations to approved work plans submitted after 8 December 2015 must comply with Schedule 15 of MRSD(MI)R. A work plan will not need to comply with the new Schedule 15 requirements **if the plan has been submitted to ERR for assessment (or has been referred or endorsed) before the regulation's proclamation date.**

Part F – Work plan dispute resolution

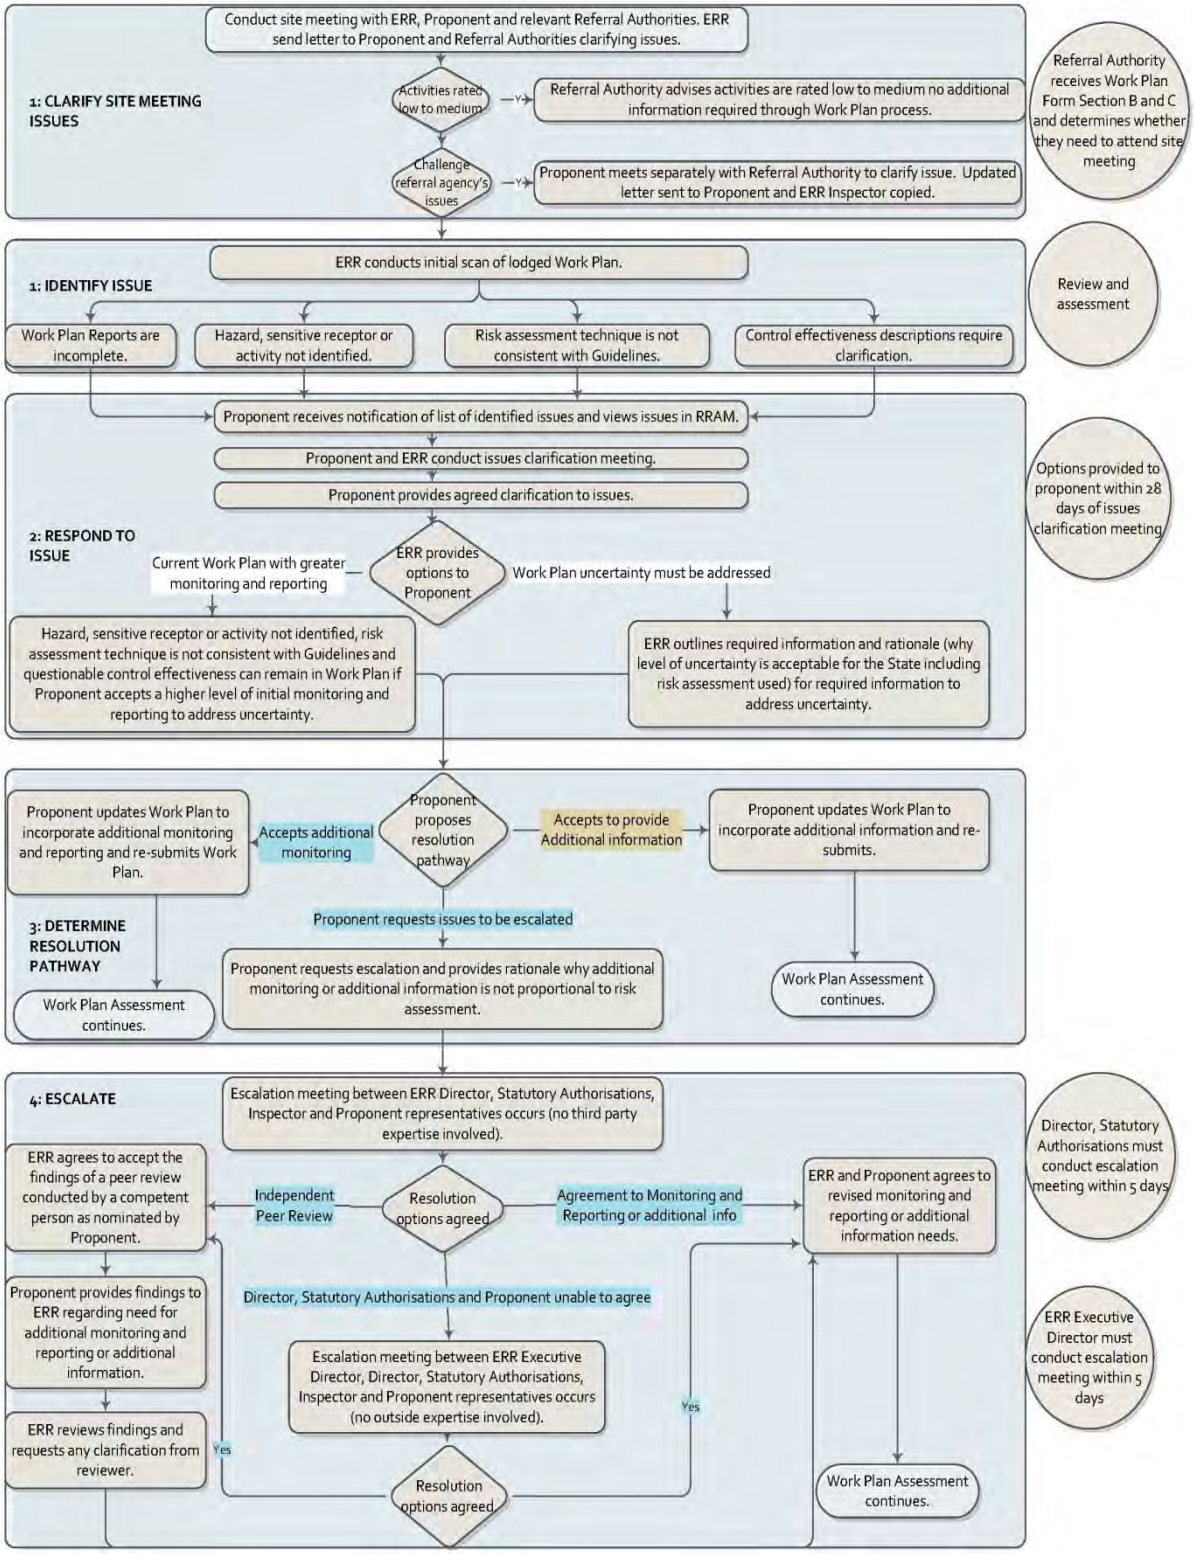
If a Tenement holder is not satisfied with – or is unable to resolve a specific issue with – ERR's assessment of a risk-based work plan, they may request (in writing) a management review by the Chief Inspector of Mines and/or the Executive Director of ERR. ERR will seek to complete a management review within five working days (**figure 6**).

If the management review identifies a deficiency in the assessment of the work plan, the Chief Inspector or Executive Director may decide to amend the assessment. The issue resolution process occurs concurrently with the assessment of the remaining activities contained in the work plan.

The process applies to only the Tenement holder challenging or clarifying conditions/controls imposed on the proposed works area.

ERR offers this informal non-statutory review process to help resolve issues early and to avoid unnecessary and costly Victorian Civil and Administrative Tribunal (VCAT) or other court processes. The review process cannot be used to challenge any conditions on the planning permit, or conditions imposed by referral authorities. Issues with a planning or referral authority decision will revert to the Victorian Civil and Administrative Tribunal (VCAT) for review.

Figure 6: Work plan assessment and approval issue resolution process



APPENDIXES

Appendix 1: Information to be supplied to ERR to identify referral authority for scheduling initial site meeting

1. Planning property report
2. Certificate of title
3. Plan of mining industry project area

Appendix 2: Information to be supplied to identified referral authorities before initial site meeting

1. Details of meeting place
2. Land tenure / status / allotment number
3. Plan of extraction or disturbed area
4. Commodity / resource type
5. Size / depth / life of proposed activity
6. Estimated total resource
7. Brief description of the proposed activity (for example, above ground or underground, blasting, dams, tailings storage facilities, hazardous waste issue etc.).

Appendix 3: Possible site meeting questions

The following questions/issues may be discussed at the initial site meeting. Use this checklist to identify information that may need to be provided in the work plan.

Discussion topic	Details
Mining proposal	• What is the estimated life of the activity? • What is the estimated/anticipated volume per year (output in tonnes or cubic metres) of the resource? • What is the estimated volume of soils and overburden to be disturbed? • What will be the operating hours?
General location information	• What road(s) are proposed to be used to enter/exit the activity area? • Are there any known inherited issues as a result of past or current land use?
Blasting	• Will blasting take place? • If so, could blasting related activity cause vibrations/noise/fly rock at the boundary of (or beyond) the activity area? If so, what would be the impact on sensitive receptors or infrastructure (including pipelines)?
Noise	• Is it likely that activity area noise will be heard at any sensitive receptor?
Dust	• Will the operations likely generate dust or spray that will be deposited or emitted outside the activity area boundary? • Will the operations likely generate any other substances listed as Class 1, 2 or 3 indicators under PEM (2007) that will be emitted outside the activity area boundary?
Community facility/private and public infrastructure	• Is known above and below ground infrastructure (electricity networks, water mains, designated waters etc.) located near the activity area? • Are known public roads, bridges or train lines located near the activity area?
Aboriginal heritage	• Are any areas of cultural heritage sensitivity or other protected areas in the proposed activity area? • Are any caves or dunes identified in the activity area? • Is a Cultural Heritage Management Plan is required?
Historic heritage	• Does the activity area contain places, sites or objects on: – the heritage overlay of the relevant planning scheme? – the Victorian Heritage Register? – the Victorian Heritage Inventory? – Must any historical heritage sites, structures or artefacts be retained as part of the post closure land form?
Flora and fauna	• Is any flora or fauna, including native vegetation, within the activity area to be removed or impacted? • Are there weeds, pests or feral animals within or from surrounding areas that could impact rehabilitation activities and/or potential land uses after closure?
Groundwater	• What is the depth to groundwater and water quality objectives as defined in the SEPP Groundwaters of Victoria? • Where are nearest groundwater users or groundwater sensitive ecosystems? • Will de-watering be required (for example, the lowering of the groundwater levels) or is the activity pit expected to intersect the water table? • Will there be any potential impacts on existing groundwater quality? Are there third party users of groundwater surrounding the activity? • Are there groundwater dependent ecosystems located within the specified distances surrounding the activity area? • Is the activity within a Groundwater Restricted Quality Usage Zone, a Water Supply Protection Area or a Groundwater Management Area?
Surface water	• What are the water quality objectives for the area defined in the SEPP Waters of Victoria? • Where are nearest water users or water sensitive ecosystems?

Discussion topic	Details
	• Are alterations to surface drainage needed (for example, waterway diversion)? If yes, will they increase the potential for flooding of adjacent land? • Are soil, overburden or proposed extracted materials (soils etc.) susceptible to erosion (created due to clearing of vegetation, problem soils etc.)? • Is there potential for soil and overburden stockpile to cause sedimentation outside the activity boundary? • Is the activity area located within a potable water catchment?
Dams	• Will there be water storages (for example, settlement pond, water storage, evaporation pond, bio-retention basin, other) or tailings storage facilities on the activity area? • Will any of the storages or tailings facilities meet the ANCOLD guidelines' criteria for a large dam? If yes, what is the type, area and embankment height of water storages or tailings facility and it's possible consequence category? • Will the storage or tailings facility be located on a waterway? • Will the storage or tailings facility receive runoff from a catchment upslope of the site? • Will any of the above storages or tailings facilities hold water that is unlikely to meet the SEPP guidelines for surface water or groundwater (or the ANZECC guidelines when a constituent is not specified)? • Will a tailings facility hold tailings that could be classed as contaminated or proscribed material? • What impact could failure of a storage or tailings facility have on public safety, infrastructure or the environment?
Geotechnical	• How will slope instability affect public safety, public infrastructure or environmental elements? • How can the site's lithology/geology and structural geology impact on slope stability? E.g. are there any active faults, dykes or shear zones (including adverse jointing) which may affect slope stability? • Is the overburden dispersive which may lead to long term erosion problems around the site? • What influence may seismic activity in the area have on slope stability? • Can elevated water levels in the batters have an impact on slope stability? • Are there areas where a perched water table may exist? • Could the proposed activity's operation and excavation methods heighten the potential for slope instability? Would such instability have any impact outside the activity area? • Are any historical voids (old mine underground workings, shafts etc.) within the activity area? • Could other adjacent land uses or features create triggers for land instability (for example, a neighbouring property that is performing blasting or surface water drainage near the batter crest)? • Will there be any crest loading, which may affect slope stability, such as an overburden dump or plant equipment situated near the crest of the open pit?
Environment – visual amenity (re overburden/ waste rock)	• Will stockpiles and overburden dump be located within the activity area? • If yes, what is the volume of material? And what is the proposed height of the largest stockpile / overburden dump?
Waste	• Will process wastewater be stored and treated within the activity area? • Will the operations (extraction and processing) generate hazardous wastes (for example, grease, oils, putrescible waste, batteries)?
Fuel	• Will fuel (for example, petrol, diesel) or other chemicals/additives be stored within the activity area? • Will refuelling, fuel storage and maintenance of machinery and equipment occur within the activity area?
Acid Mine Drainage	• Will acid sulphide soils be exposed/oxygenated during the proposed activities? • Is there potential for sulphide minerals to be present or exposed during the proposed

Discussion topic	Details
	activity (such as from overburden, waste and remnant pit shells surfaces)?
Radiation	• Is any part of the operation (extracted or processed material) going to be legally radioactive in accordance with the *Radiation Act 2005?*
Site Rehabilitation	• What is proposed for site rehabilitation and closure, and subsequent land use? • What is proposed for mine batter rehabilitation? • How will water storages and tailings storage facilities be rehabilitated? • What is proposed for surface water drainage and discharge from the activity area? • What land management or maintenance activities will be required after closure?

Appendix 4: Potential risks for consideration in the work plan (selection available in RRAM)

*"a **mining hazard** is any activity or circumstance that could pose a risk to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work."*

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)
• Air blast • Altered visual amenity • Biodiversity disturbance • Contaminated water • Excessive dust • Erosion and sedimentation • Fire • Flood • Fly rock • Ground instability, including slopes and sink-hole formation • Ground vibration, liquefaction • Unmanaged hazardous waste • Light emission • Noise pollution	• Activity – plant and equipment • Activity – blasting • Activity – drilling • Activity – overburden and waste dumps and stockpiles • Dams, drainage diversions and waterways • Fuel / chemicals storage • Geological rock types and structure • Geotechnical, including batter configuration • Seismicity • Night works • Surface water run-off • Tailings storage facilities, including pipelines	• Aboriginal h eritage • Historic heritage • Groundwater • Surface water • Biodiversity ecosystem • Air quality • Significant landscape • Crown land • National park • Public safety • Private property • Public infrastructure • Community facility

Appendix 5: Guidance for describing sensitive receptors in the vicinity of the work

Schedule 15 of the MRSD(MI)R notes information required in a work plan for mines includes:

*"A description of **sensitive receptors** (including their location), in relation to the environment, any member of the public, or land, property or infrastructure in the **vicinity** of the work"*

According to the MRSDA, the identification of quarrying hazards and assessment of risk relate to the environment, any member of the public, and land, property or infrastructure – called receptors. The MRSDA refers to Crown lands and private lands; residential, commercial and industrial development; public facilities and infrastructure; and rivers and streams. A selection of receptors is available in the RRAM field **'At risk'**. This list is not exhaustive, and the Tenement holder is responsible for identifying other receptors likely to be impacted. The Tenement holder is encouraged to describe all receptors around the project site that are likely to be potentially sensitive (if not described as sensitive receptors in **table 2**).

- **'In the vicinity of the work'** is defined by the required separation distances or buffer distances or other quantitative/qualitative references stipulated in legislation, policies or guidance material relating to those receptors.
- When receptors are in the vicinity of the work, those receptors are considered to be **sensitive receptors**. **Table 2: Guidance to identify sensitive receptors in the vicinity of the work**

Mining hazard	Receptors	Definition of vicinity	Is this a sensitive receptor?	Reference
Noise pollution	Public safety (as described in sensitive land uses and/or noise sensitive areas)	Mining industry project involving extraction, crushing, screening, stockpiling and conveying of rock, when the effective noise level for 'beneficial uses' cannot be protected in 'noise sensitive areas'	Yes	Sensitive land uses include residential premises, child care centres, preschools, primary schools, education centres and informal outdoor recreation sites. The effective noise level for 'beneficial uses' in 'noise sensitive areas' is as described in State Environment Protection Policy (Control of noise from commerce, industry and trade) No. N-1 (SEPP N-1), Applying NIRV to proposed and existing industry (EPA(publication 1413 – the Applying NIRV guide), SEPP N-1 and NIRV explanatory notes (EPA publication 1412), and *Noise from industry in regional Victoria – recommended maximum noise levels from commerce, industry and trade premises in regional Victoria* (publication 1411)

Mining hazard	Receptors	Definition of vicinity	Is this a sensitive receptor?	Reference
Excessive dust	• Air quality • Private property (as described in sensitive land uses) • Community facility (as described in sensitive land uses) • Public safety (as described in sensitive land uses)	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: • without blasting when sensitive land uses are within 250 metres • with blasting when sensitive land uses are within 500 metres • with respirable crystalline silica when sensitive land uses are within 500 metres	Yes.	Sensitive land uses (residential premises, child care centres, preschools, primary schools, education centres, or informal outdoor recreation sites) as defined in *Recommended separation distances for industrial residual air emissions* (EPA publication 1518)
Altered amenity	• Public safety (as described in sensitive land uses)	Mining industry project involving mining , crushing, screening, stockpiling and conveying of rock : • without blasting when sensitive land uses are within 250 metres • with blasting when sensitive land uses are within 500 metres • with respirable crystalline silica when sensitive land uses are within 500 metres	Yes	Sensitive land uses (residential premises, child care centres, preschools, primary schools, education centres, or informal outdoor recreation sites) as defined in *Recommended separation distances for industrial residual air emissions* (EPA publication 1518)
Air blast **Fly rock** **Ground v vibration** **Ground instability** **Noise pollution**	• Private property (as described in sensitive land uses) • Community facility (as described in sensitive land uses) • Public safety (as described in sensitive land uses) • Public infrastructure	Mining industry project involving mining: • with blasting when sensitive land uses are within 500 metres • with blasting when the requirement of ground vibration and air blast limits cannot be met • with blasting when there are infrastructure and sensitive land uses within the GRZ zone • with blasting when the effective noise level for 'beneficial uses' cannot be protected in 'noise sensitive areas'	Yes	Sensitive land uses (residential premises, child care centres, preschools, primary schools, education centres, or informal outdoor recreation sites) as defined in '*Recommended separation distances for industrial residual air emissions'* (EPA publication 1518) Ground vibration and air blast limits as described in *Environmental guidelines – ground vibration and airblast limits for blasting in mines and quarries, blasting limit guidelines v1.2* (Department of Natural Resource and Environment) GRZ zone as described in *Guidance material for the assessment of geotechnical risks in open pit mines and quarries* (DEDJTR)

Mining hazard	Receptors	Definition of vicinity	Is this a sensitive receptor?	Reference
				Effective noise level for 'beneficial use' in 'noise sensitive areas' is as described in SEPP N-1, the Applying NIRV guide, the SEPP N-1 and NIRV explanatory notes, and *Noise from industry in regional Victoria – recommended maximum noise levels from commerce, industry and trade premises in regional Victoria* (Publication 1411)
Water quality	• Groundwater • Surface water • Aquatic and terrestrial ecosystem • Groundwater dependent ecosystem • Public safety (as described in sensitive land uses and users of surface water and groundwater)	Mining project involving drilling, excavating, crushing, screening, stockpiling and conveying of rock: • with dry and wet extraction, including transport and deposition of tailings, when the protection of ecosystem and/or beneficial uses of the surface water and groundwater cannot be met	Yes	Advised by Southern Rural Water Beneficial use surface water and groundwater as described in SEPP (Waters of Victoria) (2003); and SEPP (Groundwaters of Victoria) (2003) Storage of hazardous material (for example, fuels, oils)
Groundwater supply	• Water supply – users of groundwater	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: • with dry or wet extraction when dewatering for excavation is proposed		Advised by Southern Rural Water: Groundwater Supply Protection Area, Groundwater Management Area
Ground instability	Heritage sites • Aboriginal heritage • Historic heritage Environmental features • Surface water • Biodiversity Ecosystem • Significant landscape • Crown land	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: • without blasting with wet or dry extraction when there are heritage sites, environmental features, public infrastructure and sensitive land uses within the GRZ zone • on land of historical mine site (e.g. underground shaft)	Yes	Sensitive land uses (residential premises, child care centres, preschools, primary schools, education centres, or informal outdoor recreation sites) as defined in *Recommended separation distances for industrial residual air emissions* EPA publication 1518) GRZ zone as described in *Guidance material for the assessment of geotechnical risks in open pit mines and quarries* (DEDJTR)

Mining hazard	Receptors	Definition of vicinity	Is this a sensitive receptor?	Reference
	• National park Public infrastructure, which includes but is not limited to roads, bridges, railways, pipelines, power lines and human-made drains Public safety (as described in 'sensitive land'[2] uses and users of roads/bridges/railways)	• For power lines mining on land within 60 metres of a major electricity transmission line (220 kilovolts or more) or an electricity transmission easement. Other infrastructure in the GRZ.		Advised by Heritage Victoria Victorian Planning Provision Clause 66
Erosion and sedimentation	Surface water Public infrastructure (water related)	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock with or without blasting, with wet or dry extraction, when the area is close to water-sensitive assets		Proximity to assets as advised by Melbourne Water pre-feasibility advice (http://www.melbournewater.com.au/planning-and-building/land- development-process/pages/feasibility- checks.aspx), as per Dial Before You Dig Designated watercourses, lakes or floodways.
Flood	Surface water Significant landscape Land	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: • in Special Areas declared under s27 of the *Catchment and Land Protection Act 1994* • on land that has been identified in this scheme as flood prone • on land that has been identified in this scheme as being subject to high erosion risk or areas • on land identified as being subject to salinity management	Yes	Victorian Planning Provision Clause 66
Fire	Crown land National park	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock, on Crown land or land abutting Crown land, other than a government road	Yes	Victorian Planning Provision Clause 66

[2] *Recommended separation distances for industrial residual air emissions' EPA publication No 1518*

Mining hazard	Receptors	Definition of vicinity	Is this a sensitive receptor?	Reference
Biodiversity disturbance	Biodiversity Ecosystem	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: on land when the use or development involves the removal or destruction of native vegetation if the total area to be cleared is 10 hectares or greater in areas with communities or taxa listed or critical habitat determined under the *Flora and Fauna Guarantee Act 1988* on land that has been identified in this scheme as containing sites of flora or fauna significance	Yes	Victorian Planning Provision Clause 66
Offsite traffic	Public infrastructure Public safety	Mining industry project involving mining, crushing, screening, stockpiling and conveying of rock: on land that abuts a local road that intersects with a road declared as a freeway or an arterial road under the *Road Management Act 2004* and if the development is expected to increase traffic movement at the intersection of the local road and the declared road by 10 per cent or more on land that abuts a road declared as a freeway or an arterial road under the *Road Management Act 2004*. This does not apply to a development that generates less than 100 commercial trips per day, with road works at the entrance to the site built in accordance with the requirements of the Roads Corporation and when the declared road is not a freeway.	Yes	Victorian Planning Provision Clause 66

Appendix 6: Example of controls for managing risk from mining activities

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
Noise emissions	• Activity – plant and equipment • Activity – blasting • Activity – drilling • Night works	• Public safety • Private property • Community facility	For applicable standards or thresholds, see: • SEPP (Noise from industry in regional Victoria) (2011) (NIRV) • SEPP (Control of noise from commerce, industry and trade) (2001) (SEPP N-1)	• Equipment orientation and position • Equipment maintenance regime in accordance with manufacturer specifications • Engineering attenuation controls (that is, mufflers, acoustic screens and enclosures) • Restricted operation of noise generating equipment • Overburden stockpiles located to reduce noise emissions at sensitive receptors. • Noise / acoustic barriers or bunds • Engineered noise abatement of crushers, mills grizzlies, pumps, conveyors, trommels and vibrating screens when practical
Dust emissions	• Activity – plant and equipment • Activity – blasting • Activity – drilling • Activity – overburden dumps and stockpiles • Tailings storage facility	• Air quality • Public safety • Private property • Community facility	For applicable standards or thresholds, see: • SEPP (Air quality management) (2001)	• Reduce vehicle speed. • When clearing vegetation, minimise exposed areas by progressively clearance. • Implement watering of exposed areas during dry periods and restrict site traffic to areas serviced by water tanker. • Apply chemical bonding agents to exposed areas / unsealed roadways. • Minimise vehicle movement. • Minimise exposed areas. • Implement fixed sprinkler system. • Implement mobile sprinkler system. • Cease works during high wind conditions (wind speeds over 50 kph). • Apply water cart on roads within the site. • Seal internal roads when practicable.

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
				• Use dust suppressants on topsoil stockpiles. • Progressively establish vegetation on topsoil/overburden stockpiles and rehabilitated landforms. • Use enclosures for dust generating equipment (for example, an enclosure around a crusher).
Air blast **Fly rock** **Ground vibration**	• Activity – blasting • Activity – drilling	• Public safety • Private property • Public infrastructure • Community facility	For applicable standards or thresholds, see: • Ground vibration (peak particle velocity) below 5mm/s in at least 95 per cent of cases in a 12 month period, and not exceeding 10mm/s at any time • Airblast below 115dB(L) in at least 95% of cases in a 12 month period and not exceeding 120dB(L) at any time	• Pre-calculate the effect to ensure the charge load is correct. • Use some kind of structure to minimise fly rock (for example, blasting mats). • Consider using controlled blasting techniques to minimise slope damage. These techniques include buffer blasting, trim blasting, pre- or mid-split blasting, post-split blasting and line drilling. • Propose a blasting technique, considering geology and geological structures' face heights and orientation, any topographic shielding, stemming heights, blast hole to burden ratios, etc.
Unmanaged hazardous material / waste	Fuel / additive storage and handling	• Groundwater • Surface water • Biodiversity • Ecosystem • Air quality • Significant landscape • Crown land • National park • Public safety • Private property • Public property • Community facility	• Bunding guidelines (EPA publication 347) • SEPP (Waters of Victoria) (2003) • AS 1940-2004 The storage and handling of flammable and combustible liquids	For protection against potential impact from **stored fuel** on site: • The quantities of fuel stored on site shall be kept to a minimum, and must not be stored in or adjacent to surface waters, drainage lines or floodplains, unless the storage facilities prevent them from coming into contact with surface waters. • Refuelling of plant and equipment shall be undertaken in designated areas, away from waterway areas and drainage lines. • Re-fuelling should be undertaken in bunded areas only. Or, if a bunded area is not available, a portable tray is to be used to prevent on-ground spill. • Any area on which a vehicle can stand while being fuelled shall be so graded that spilled liquid will flow

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
				away from any building, and will not flow off the site. • Procedures for fuel spills will be documented. • A spill kit(s) of the appropriate size, quantities and contents applicable to the site shall be supplied. • Employee induction will include spill response information (location of spill kits, and how to clean up spills). • Concrete hard stands, bunding and triple interceptors will be used as primary controls. • Any drainage from a hardstand area where fuels and lubricants are stored and used will be directed to a sump and triple interceptor. • Spill prevention and clean-up equipment will be readily available in the vicinity of all plant and machinery, including mobile and fixed fuel storages. • Spills of fuels, lubricants and/or hazardous materials will be cleaned up as quickly as practicable. Such spillage should not be cleaned up by hosing, sweeping or otherwise releasing such contaminant into waterways. Equipment and soil contaminated by fuels, lubricants, hazardous materials, and clean-up substances which cannot be salvaged should be disposed of in an approved waste facility.
			• *Occupational Health and Safety Act 2004* • *Australian Code for Transport of Dangerous Goods by Road and Rail* • *Code of Practice for the Storage and Handling of Dangerous Goods (2013)*	Protection against potential impact from **stored chemicals/ additives** on site: • The quantities of chemicals stored on site shall be kept to a minimum, and must not be stored in or adjacent to surface waters, drainage lines or floodplains, unless the storage facilities prevent them from coming into contact with surface waters. • Procedures will be documented for the storage and handling of chemicals. • Procedures will be documented for chemical spills.

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
			•	•
Unmanaged hazardous material / waste	Tailings Storage Facility and associated infrastructure, seepage or overflow	• Groundwater • Surface water • Biodiversity • Ecosystem • Significant landscape • Crown land • National park • Public safety • Private property • Public property • Community facility	• *Guidelines on risk assessment* • *ANCOLD guidelines on the consequence category for dams (2012)* • *ANCOLD guidelines on selection of acceptable flood capacity for dams (2000)* • SEPP (Waters of Victoria) (2003) • *Environmental guidelines – management of water in mines and quarries: Victorian legal and policy requirements* • Consequence Screening Tool for Small Dams (2014) (Department of Environment and Primary Industries)	For protection against potential impact from **tailings storage facilities**: • Suitable dam liner permeability • Spillway capacity (for example, capacity can pass the one in 10,000 year flood event) • Appropriately designed freeboard • Planning to ensure sufficient material (rock, clay, sand and soil) is available for covering the tailings in final rehabilitation • Battering of external dam walls to allow effective revegetation and prevent erosion (slopes of 1V: 3H or shallower are recommended). • Installation of cut-off drains to reduce water flowing onto the dam surface, and long-term collection and treatment of seepage from the dam For protection against potential impact from process water: • All storages are lined, to prevent seepage to groundwater. • Bunding is placed around processing facilities to contain any water spillage. • Pipelines are inspected regularly to ensure structural integrity and no leaks. • Ongoing sampling and monitoring of surface water and groundwater are done to ensure no contamination.
	Surface water (on site)		• SEPP (Groundwaters of Victoria) (2003) • *National water quality management strategy: water quality management*	For protection against potential impact **on surface water:** • Drainage control works that divert surface water away from extraction areas and control erosion • Culvert and channel capacity that can convey

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
			– *guidelines for groundwater protection in Australia* (1995)	the relevant flood event design criteria (for example, one in 20 years) • Appropriately sized sediment ponds • Diversion of runoff from the up gradient catchment area around the crest of the slope • Diversion of runoff from the upper benches along drainage channels (toe drains) constructed on berms that allow gravity drainage to low points • Placement of surface water collection facilities on individual berms to shed localised runoff water as quickly as possible • Direction of all surface water from the disturbed areas to the pit floor sump. In the event of the pit floor sump becoming full, it may be used in on or offsite irrigation. • Document standard controls in the form of a surface water management plan and/or drainage management plan.
Water quality	• Activity – drilling • Surface water (on site)	• Groundwater • Surface water • Biodiversity • Ecosystem • Significant landscape • Crown land • National park • Public safety • Private property • Public property • Community facility	• SEPP (Waters of Victoria) (2003) • *SEPP (groundwaters of Victoria) (2003)* • *Guideline construction techniques for sediment pollution control (EPA 1991)*	For protection against potential impact **on groundwater** • Apply high standards in design, construction, operation, maintenance and decommissioning of wells. • Minimise chemical use and use environmentally benign alternatives. • Monitor groundwater (levels and quality). • Remove the direct pathway to groundwater by lowering groundwater levels below the pit levels. • Have a contaminants spill kit available at all times when mobile equipment is being refuelled near waterways or any minor servicing and/or simple maintenance tasks are undertaken on site. Conduct any major servicing / repairs in a contained facility.

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
				• Drain any areas where activities are being undertaken to ensure no water leaves the site without first going through a sediment retention basin. For protection against potential impact **from surface water generated on site:** • Maximise the use of onsite water to limit offsite discharges. Document standard controls in the form of a surface water management plan and/or drainage management plan.
Water quality	Waste rock dump	• Groundwater • Surface water • Biodiversity • Ecosystem • Significant landscape • Crown land • National park • Public safety • Private property • Community facility	• *Industrial waste resource guidelines* (EPA) • *Radiation Act 2005* • SEPP (Waters of Victoria) (2003) • SEPP (groundwaters of Victoria) (2003) • ERR Tailings Storage Facilities guideline	For protection against potential impact **of any contaminated material in EPA guidelines (including radioactive waste):** • Conduct staff and contractor training and induction on the presence of radiation within the work authority area • Limit exposure to and spread of dust by minimising potential dust generating surfaces and using dust control measures. (seals, water suppression etc.). • Ensure trucks or other vehicles transporting radioactive material are covered to prevent spillage. • Conduct regular monitoring using gamma monitors. • Limit potential for seepage and uncontrolled runoff by using under-dump liners and interception drainage; • Conduct groundwater monitoring (water quality sampling).
Water quality	Waste rock dump	• Groundwater • Surface water • Biodiversity • Ecosystem	• *Victorian best practice guidelines for assessing and managing coastal acid sulfate soils* • *Victorian coastal acid*	For protection against potential impact **of acid drainage from waste rock**: • Identify potentially problematic materials. • Actively manage problematic materials to reduce oxygen ingress and reduce the flow of water, which

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
		• Significant landscape • Crown land • National park • Public safety • Private property • Community facility	*sulfate soils strategy* • *Industrial waste management policy (waste acid sulfate soils)* (EPA 1999)	may include encapsulation, isolation and/or neutralisation of material.
Erosion and sedimentation	• Activity – plant and equipment • Activity – overburden dumps and stockpiles • Dams and waterways • Tailings storage facility • Disturbed, unrehabilitated ground	• Surface water • Biodiversity • Ecosystem • Crown land • National park • Private property • Public infrastructure	For applicable standards or thresholds, see SEPP (Waters of Victoria) (2003)	• Drainage control works to divert surface water away from extraction areas • Culvert and channel capacity that can convey the relevant flood event design criteria (for example, one in 20 years) • Appropriately sized sediment ponds • Diversion of runoff from the upgradient catchment area around the crest of the slope • Diversion of runoff from the upper benches along drainage channels (toe drains) constructed on berms that allow gravity drainage to low points • Placement of surface water collection facilities on individual berms to shed localised runoff water as quickly as possible • Direction of all surface water from the disturbed areas to the quarry floor sump. • Use of the quarry floor sump, if full, in onsite or offsite irrigation • Adequate surface water drainage control along berms • Rip-rap protection of bench toes and erosion matting • Windows/crest berms on individual berms to prevent run on to the bench face below • Sediment pit pumping station at the quarry floor. • For erosion control of waste dumps/stockpiles, final slopes of 1V: 3H or shallower, with benches to

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
				break long slopes • Maximise use of onsite water to limit offsite discharges • Standard controls documented in the form of a surface water management plan and/or drainage management plan
Biodiversity disturbance	• Activity – plant and equipment • Activity – blasting • Activity – overburden dumps and stockpiles • Dams and waterways • Fuel / additive storage • Tailings storage facilities • Ground disturbance in buffer or vegetation protection areas	• Groundwater • Surface water • Biodiversity • Ecosystem • Significant landscape • Crown land • National park		• Fence and sign native vegetation to inform site personnel of no-go areas. • Maintain a buffer zone to ensure an effective screen between the relevant operation activities and surrounding biodiversity. • Avoid disturbing the root zone of a tree, which generally extends to the edge of the canopy plus half the radius of the canopy again. • Use species that are indigenous to the area and appropriate to the site's Ecological Vegetation Class (EVC) when establishing plants within the buffer zone. • Prepare a wildlife management plan/ strategy to address potential interactions with wildlife. • Complete a targeted survey (by a qualified ecologist) of the proposed disturbance area. • Complete a habitat hectare assessment. • Locate and secure required offsets. (Offsets must be in place before any clearing activities taking place.) • Produce a post activity restoration plan for the site. • Collect seeds of remnant vegetation and establish a suitable seed bank. • Refer to DELWP guidelines on changes to native vegetation policy.
Cultural heritage disturbance	• Activity – plant and equipment • Activity – blasting	• Aboriginal heritage • European heritage		• Mitigation conditions/ measures, including fencing, burial monitoring, site recording, test excavation, complete archaeological investigation, and

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
	• Activity – overburden dumps and stockpiles • Dams and waterways • Tailing storage facilities			interpretation • Contingency measures for the discovery of new archaeological relics (s132 Heritage Act 1995) • Approved Cultural Heritage Management Plan
Ground instability	• Activity – plant and equipment • Activity – blasting • Activity – drilling • Activity - excavations • Activity – overburden dumps and stockpiles • Dams and waterways • Geological structure • Groundwater • Surface water • Tailings storage facilities	• Surface water • Crown land • National park • Public safety • Private property • Public infrastructure • Community facility		• Design of flatter angled slopes • Berms or fences to catch any rock falls • Surface drainage controls. • Safety bunds established along the edge of pit ramps and quarry faces. • Safety bunds to be constructed at appropriate height, width and durability to withstand forces from the vehicles moving through that area • Dewatering of batters through pumping, and installation of horizontal drains along batters • Regular pit inspections by appropriate operator staff to confirm safety and absence of adverse stability issues • Annual review of activity level and the likelihood of instability • Blasting controls, such as using pre-split or post-split blasting techniques on terminal walls • Operation within a safe set-back zone from the infrastructure/facility by following the appropriate GRZ assessment process and demonstrating set-back distances are safe through sound geotechnical investigation, which may include analyses (as per *Guidance Material for the Assessment of Geotechnical Risk in Open Pit Mines and Quarries*) • Management plans, such as Ground Control Management Plan for the site. The GCMP is to have a Trigger Action response Plan linked to the site

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
				Emergency Response Plan.
Flood and discharge during a flood event	• Dams and waterways • Surface water • Tailings storage facilities	• Surface water • Biodiversity • Ecosystem • Significant landscape • Public safety • Private property • Public infrastructure • Community facility	• SEPP (Waters of Victoria) (2003) • *Guideline construction techniques for sediment pollution control* (EPA 1991)	• Appropriately designed, constructed and maintained water and tailings structures with adequate retention and controlled discharge capacity • Water and tailings management plan • Water and slimes storage management plan, including dam wall stability • Inclusion of relevant authority in the community engagement plan and emergency risk management plan • Employee induction
Visual amenity	• Activity – plant and equipment • Activity – overburden dumps and stockpiles • Dams and waterways • TSF	• Public safety (aesthetic value) • Private property (aesthetic value)		No mining within 1 kilometre of the boundary of a declared national park
Light emission	Night works	• Public safety • Private property		• Keep lights off when not needed. • Mount lights low down, with lowest intensity for the job. • Stop all light escaping upwards and outwards. • Undertake close analysis and judicious use of terrain and vegetation before commencing the design of a facility, to significantly reduce the potential for light spill
Fire	• Fire generating activity (ignition source) • Fuel/additive storage	• Biodiversity • Ecosystem • Air quality • Crown land		• Maintenance of firebreaks • Inclusion of bushfire authority in community engagement plan and emergency risk management plan • Employee induction

Potential risk hazard (includes activity or circumstances)	Potential risk source (includes activity or circumstances)	Potential receptors at risk (includes environment, member of public, land, property, infrastructure in the vicinity of the work)	Objectives or outcomes to be met	Example of controls
		• National park • Public safety • Private property • Public infrastructure • Community facility		• Fire management plan

Appendix 7: Consequence rating (selection available in RRAM)

The following examples guide the selection of the consequence rating in RRAM, in relation to the level of risk posed to environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work. The consequence rating is selected after the implementation of a standard control and/or additional control. The examples are not exhaustive, and the Tenement holder should make reasonable judgement of the correct consequence rating for their proposed mining project.

Consequence rating	Public safety	Community facilities, including property and infrastructure	Land and environment
Critical	• One or more fatalities or life threatening injuries or illness • Public exposed to a severe, adverse long-term health impact or life-threatening hazard	• Services suspended for an extended (years) period • More than 100,000 people who are unable to access the service or experiencing disrupted access to the service	• Irreversible widespread damage to: – listed species (biodiversity) – groundwater dependent ecosystems – groundwater and surface water quality • Significant contribution to multiple environmental pollution events
Major	• One or more injuries or illness requiring surgery or resulting in permanent disablement • Public exposed to a hazard that results in surgery or permanent disablement • Hospitalisation for extensive treatment from injury or illness for more than four weeks	• Services suspended for a major (months) period • 50,000 – 100,000 people who are unable to access the service or experiencing disrupted access to the service	• Extensive, reversible and long-term (remediation lasts longer than three years) or irreversible and localised damage to: – listed species (biodiversity) – groundwater dependent ecosystems – groundwater and surface water quality • Damage that requires specialist equipment and resources from government agencies
Moderate	• One or more injuries or illness requiring treatment by a physician or hospitalisation • Public exposed to a hazard that could cause injuries or health effects requiring treatment by a physician or hospitalisation • Hospitalisation (for observation, for example) for injury or illness for less than four weeks	• Services suspended for a moderate (weeks) period • 1,000 – 50,000 people who are unable to access the service or experiencing disrupted access to the service	• Localised, extended (remediation lasts less than three years) and reversible damage to: – listed species (biodiversity) – groundwater dependent ecosystems – groundwater and surface water quality • Damage that requires specialist equipment from government agencies
Minor	• One or more injuries or illness requiring treatment by a qualified first aid person • Public exposed to a hazard that could cause injuries or adverse health effects requiring treatment by a qualified first	• Services suspended for a minor (days) period • 100 – 1,000 people who are unable to access the service or experiencing	• Localised, temporary (remediation lasts less than one year) and reversible damage to: – listed species (biodiversity) – groundwater dependent ecosystems

Consequence rating	Public safety	Community facilities, including property and infrastructure	Land and environment
	aid person • Medical treatment required for injury or illness (but not resulting in hospitalisation) – not a Lost Time Injury	disrupted access to the service	– groundwater and surface water quality • Damage that requires specialist advice from government agencies
Insignificant	• An injury or ailment that does not require medical treatment by a physician or a qualified first aid person (such as minor bruises, cuts, abrasions involving only local first aid)	• Services suspended for a negligible (hours) period • Fewer than 100 people who are unable to access the service or experiencing disrupted access to the service	• Superficial, short-term damage with cosmetic remediation required for impacts on: – listed species (biodiversity) – groundwater dependent ecosystems – groundwater and surface water quality • Damage that does not require any involvement from a government agency

Appendix 8: Likelihood rating (selection available in RRAM)

Rating	Description of rating	Probability	Historical
Almost certain	High probability of the consequences occurring during the project life	Has a greater than 90 per cent chance of occurring after the implementation of a standard control and /or additional control	Has occurred several times in the past year in the mining industry and in each of the previous five years in Victoria
Likely	Significant probability of the consequences occurring during the project life	Has a 70–90 per cent chance of occurring after the implementation of a standard control and /or additional control	Has occurred once or twice in the past year in the mining industry and in each of the previous five years in Victoria
Possible	Even probability of the consequences occurring during the project life	Has a 30–70 per cent chance of occurring after the implementation of a standard control and /or additional control	Has occurred in the past five years in the industry,
Unlikely	Low probability of the consequences occurring during the project life but not negligible	Has a 5–30 per cent chance of occurring after the implementation of a standard control and /or additional control	Has occurred once or twice in the industry
Rare	Very low probability of the consequences occurring during the project life but not impossible	May occur in exceptional circumstances – that is, has less than 5 per cent chance of occurring after the implementation of a standard control and /or additional control	Unheard of in the industry

Appendix 9: Example narrative of risk rating (as calculated in RRAM)

The following table contains example narratives for various risk ratings (low, medium, significant, high). The Tenement holder should describe the risk posed to the environment, to any member of the public, or to land, property or infrastructure in the vicinity of the work.

Activities or circumstances that create a hazard or source of hazard	Risk rating			
	Low	Medium	Significant	High
Blasting	A small blast charge occurring kilometres away from any sensitive receptor	One medium blast charge occurring between 500 metres and 1 kilometre from any sensitive receptor over a period of time Many small blast charges occurring between 500 metres and 1 kilometre from any sensitive receptor over a period of time	One large blast charge occurring within 50 metres and 500 metres of any sensitive receptor A few medium blast charges occurring between 50 metres and 500 metres of any sensitive receptor over a period of time Many small blast charges occurring between 50 metres and 500 metres of any sensitive receptor over a period of time	A single large blast charge in close proximity (for example, 50 metres) of sensitive receptors A few medium blast charges occurring within 50 metres of any sensitive receptor over a period of time Many small blast charges occurring within 50 metres of any sensitive receptor over a period of time
Dams	A small standalone dam with no reporting catchment	A medium size standalone dam with no reporting catchment	A large standalone dam with no reporting catchment and moderate levels of constituents of concern Medium size dam with a small reporting catchment and medium levels of constituents of concern The potential for flooding of adjacent land impacting private/public infrastructure and/or temporary contamination of land and waterways	A large dam (for example, high wall) with high levels of constituents of concern and a large uncontrolled catchment reporting to it The potential for flooding of adjacent land placing population at risk and/or irreversible/ permanent contamination of land and waterways
Hazardous waste	Low volume of waste	Medium volume of waste	Presence of hazardous materials	Presence of hazardous materials
Noise and air quality[3]	No sensitive receptors within 2 kilometres	Noise and air quality assessment within the noise	Noise and air quality modelling on or just exceeding noise thresholds	Noise and air quality modelling exceeding or significantly

Activities or circumstances that create a hazard or source of hazard	Risk rating			
	Low	Medium	Significant	High
		and air quality threshold Sensitive receptors just 500 metres from the work authority area Some existing barriers (for example, hills, trees, industrial zone) that will mitigate noise impacts	Sensitive receptors within 50 and 500 metres of the work authority area boundary Some existing barriers (for example, hills, trees, industrial zone) that may mitigate noise impacts	exceeding noise thresholds Sensitive receptors within 50 metres of the work authority area boundary
Additives	Minor spill that can be fully contained within a small area Minimal effort needed to clean up	Spill that can be contained onsite Effort needed to clean up Possible impact on site operations	Spill that migrates offsite, impacting neighbouring properties and creating potential human safety issues Significant effort needed to clean up Impacts on site operations	Spill that migrates offsite onto neighbouring properties and surface waters Impact of public safety Significant effort needed to clean up Significant impact on site operations
Slope instability	No sensitive receptors located within the GRZ (GRZ4) (=4H)	There are sensitive receptors (in part or whole) within the final GRZ. In an instability incident, the impact would be low (for example, a dirt road in a remote location is impacted by batter failure but does not need to be remediated immediately because it not used). An instability incident is unlikely, based on a precedent for how proposed slopes are to be designed in such geology, a clear absence of adverse triggers for stability, and no known past problems.	There are multiple sensitive receptors located with the final GRZ. In the case of an instability incident, the consequence for each sensitive receptor would be low but would collectively create a significant impact. There is a single sensitive receptor located within the final GRZ. In the case of an instability incident, the consequence would be significant (for example, the partial loss of public facility resulting in the service being unavailable to the community for some time). An instability incident is likely, as indicated by no precedent to guide how the proposed slopes are to be designed, adverse triggers for instability are known or likely, or at least one past instability problem.	There exists one or more sensitive receptor within the final GRZ and, if any sensitive receptor is impacted by an instability incident, the consequence would be assessed as critical (for example, it would result in death or serious injury to the public, loss of a protected ecosystem, or loss of a public service resulting in long term disruption to significant number of people). An instability incident is almost certain, as indicated by no previous precedent to guide how the proposed slopes are to be designed, the presence

[4] Victorian Planning Provisions 32.08 (2013) – General Residential Zones

Activities or circumstances that create a hazard or source of hazard	Risk rating			
	Low	Medium	Significant	High
				of several known and recognised instability triggers and / or several past instability problems.
Historic heritage		Reuse of existing pits with no associated historic machinery or foundations	Mining of pebble dumps (deep lead) The work authority area features Victorian Heritage Register places and objects, multiple sites where aggregate elevates significance, the presence of rare mining machinery and other relics, lonely graves and burial grounds, a settlement site or the probability of new sites being discovered.	Mining of mullock heaps (quartz and deep lead) Reuse of mining or processing areas with historic mining machinery and/or foundations The work authority area features Victorian Heritage Register places and objects, multiple sites where aggregate elevates significance, the presence of rare mining machinery and other relics, lonely graves and burial grounds, a settlement site or the probability of new sites being discovered.
Groundwater Level	Water table will not be intersected and groundwater levels will not be impacted by mining activities.	Water table will be intersected and low groundwater inflows can be controlled directly from the pit as required, with draw-down impacts beyond the licence area acceptable	Water will be intersected and a dewatering scheme is required to lower groundwater levels beneath the pit with drawdown impact extending beyond the licence area causing a major groundwater level impact sensitive receptors	Water will be intersected and a dewatering scheme is required to lower groundwater levels beneath the pit with unacceptable drawdown impact extending beyond the licence area to impact sensitive receptors.
Groundwater Quality	Water table will not be intersected and/or existing groundwater quality is poor and there are little or no surrounding users or sensitive receptors.	Potential changes in groundwater quality are acceptable. Existing groundwater quality is reasonable and there are nearby groundwater users or sensitive receptors.	Potential changes in groundwater quality alter the beneficial uses of the groundwater and impacts limited number of adjacent users and/or sensitive receptors who rely on groundwater.	Changes in groundwater quality alter the beneficial uses of the groundwater and render it unusable. Significant number of adjacent users and/or sensitive receptors who rely on groundwater are impacted

Appendix 10: Guidance for preparing preliminary slope instability impact assessment

The sole purpose of the Preliminary Slope Instability Impact Assessment is to determine the level of potential geotechnical instability. The purpose is not to propose or assess any additional controls. The information provided should be sufficient for the proponent, ERR, and any relevant asset holder to understand the instability in order to have an informed and objective assessment of required controls, ie, what, if any, further investigations or studies are needed to control the potential instability. Most of the information required to produce the Preliminary Slope Instability Impact Assessment report should be drawn from existing data held by the proponent and from public sources. The extent of the GRZ, the location and nature of the sensitive receptors will determine the scope of information required for the Preliminary Slope Instability Impact Assessment report. If there is no clear pathway for possible slope instability to impact a sensitive receptor, or the sensitive receptor is at the limits of the GRZ, or the potential consequence of the sensitive receptor being impacted is low to moderate, basaed on information provided by the relevant Referral Authority, the Preliminary Slope Instability Impact Assessment report should be relatively short.

Note: Relevant information from the preliminary slope instability impact assessment must be incorporated in sections B.2.1a–B.2.2d (and B.2.2f if applicable) of RRAM.

Guidance on report structure	Explanation	Supporting map (A3 at a scale of 1:1000) to show following features
GRZ	• Establish and justify the GRZ in accordance with *Guidance material for the assessment of geotechnical risk in open pit mines and quarries* – see http://www.energyandresources.vic.gov.au/earth-resources/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/guidance-material-for-the-assessment-of-geotechnical-risks-in-open-pit-mines-and-quarries)	GRZ
Sensitive receptors	• Establish or confirm receptor locations/types/sensitivities and impact pathways. Identify high value sensitive receptors based on available information and from relevant referral authority. • Identify asset owner's requirements/ guidelines for any asset in the GRZ (for example, utility installations near sewers, drains and water mains (Melbourne Water 2009) – see http://www.melbournewater.com.au/Planning-and-building/Forms-guidelines-and-standard-drawings/Documents/Utility-installation-guidelines.pdf).	Location of sensitive receptors within the GRZ
Batters and slopes	• Identify all proposed terminal quarry batters (including both toe and crest). • State proposed face heights, slope and bench details, overall and batter scale heights. • Describe the proposed terminal batter ranges (for example, one in three) and the geotechnical design assumptions (for example, groundwater systems).	All infrastructure facilities to be constructed, including overburden dumps and slimes dam, drainage and outlets, water storages
Geotechnical and geological information	• Provide available geological and geotechnical information. Include geological and geotechnical information already provided for obtaining the work authority (for example, past exploration data). Additional information could include geophysical surveying, interpretation and modelling drilling logs, imagery of the site area, regional and local geology interpretation, geological mapping, and regional stress	

Guidance on report structure	Explanation	Supporting map (A3 at a scale of 1:1000) to show following features
	field information. Information on intact rock material properties – • such as unit weight, porosity, compressive strength, tensile strength, friction angle, cohesion, and elastic constants – together with rock mass properties – such as shear strength, deformation modulus, normal and shear stiffness – may be required for modelling during the stability analysis phase. It should be obtained before that phase (applicable to risks assessed as significant or above).	
Potential instability Triggers	• Describe any adjoining activities that may impact on the stability of the operation (for example, other mining operations, fire, flooding, residential zone/easements). • Determine any past precedence of forming similar batters in a comparable geological setting (for example, the characteristics of a similar (uniform) stratigraphical setting such as alluvial sand, gypsum operations). • If extraction is expected to intersect groundwater, consider how the water table will need to be managed to maintain batter stability. • State whether the area is susceptible to natural faults or seismic activity, and describe an earthquake hazard setting from sources such as the Geoscience Australia website. • Identify any historical instability related to the type of extraction activities proposed. Gather data from databases of events, regional observation and the council. • If blasting, indicate the potential impact of blasting on instability.	• Location of adjoining activities that may impact on the stability of the operation • .Available overlays (for example, from local council) • Overlay earthquake hazard map from GeoScience Australia website • Location of any known past instability incidents
Risk assessment	• Describe potential impact pathways. Potential impact pathways include a risk statement or description. • For each risk statement or description, state a threshold or the acceptance criteria to be applied to the sensitive receptor. • For each potential impact pathway, identify standard batter and slope design controls that will be applied to avoid, minimise or mitigate any potential impact on the sensitive receptors. No additional controls are to be included in the preliminary slope instability impact assessment. • Based on the preliminary instability impact assessment and the applied controls, state whether each potential instability issue identified is low, medium, significant or high. Significant or high • If the identified instability issue is rated significant or above, then stability analysis is required. The type of stability analysis is largely governed by the anticipated failure modes, the scale of the slope and the available data. Numerous slope	• Location of significant and high instability issues and sensitive receptors

Guidance on report structure	Explanation	Supporting map (A3 at a scale of 1:1000) to show following features
	stability packages exist; the quarry operator must determine and verify the package suited to the conditions at their operation. The main types of slope stability analysis include: • kinematic analysis of structurally controlled failures – this is the analysis of the removability of rock blocks from the slope without referring to the forces that cause them to move. It is based on stereographic projections. Mainly applied for batter designs, it may also be used for large scale slope design, if structures control any anticipated failure. • limit equilibrium analysis – this two dimensional method of analysis is widely used for the computation of Factor Of Safety against rotational shear failure in soil slopes. The analysis can be applied to assess the FOS of structurally controlled 'kinematically unstable' rock block and wedges in batter and inter-ramp scale. It can also be used to assess the FOS against failure through rock material or rock mass in batter, inter-ramp and overall slopes. • numerical analysis – this is based on numerical modelling tools such as finite element and distinct element methods. It can overcome some of the limitations in the limit equilibrium analysis, in that it can model complex rock masses and the deformation and displacement of the failing mass. For industry acceptable guidelines for factors of safety and probability of failure values, see summary in Guidelines for open pit design (Stacey and Reid 2009).	

Appendix 11: Recommended information requirement in risk treatment plan

The risk treatment, or management, plan is to contain *"control measures to eliminate or minimise, as far as reasonably practicable, the identified risks associated with mining hazards; and specifies the objectives, standards or acceptance criteria that each control measure or a combination of control measures will achieve"*

The following tables provide examples of how to describe unique aspects of an additional control as per the control design effectiveness criteria in appendix 12. Examples have been provided for noise, air quality, blasting, dams and slope instability. Tenement holders should talk to ERR or the relevant referral authority about the information needed to demonstrate the effectiveness of a proposed additional control. The information should be consistent with the scope outlined in control design effectiveness criteria.

Noise

Control design appropriateness	Control modelling and simulation	Monitoring and reporting
• Description of the local terrain and meteorological conditions • Description of the level and source of influences on the existing noise environment at the nearest sensitive receptors • Potential future changes to the number or location of sensitive receptors, such as proposed housing developments • Description of the design of additional noise control measures. Measures to be considered include: – Earth bunds – Barriers – Enclosures – Damping – Attenuators – Broadband warning alarms – Procedural noise control measures (i.e. the use of certain plant at certain times) • Description of how additional controls will minimise noise emissions and impacts on sensitive receptors	• Prediction of noise levels at all potential affected noise sensitive areas, using an industry recognised noise prediction computer model. Include details on background noise studies and modelling assessments to demonstrate compliance with thresholds.	• Implementation of a noise monitoring plan if the predicted noise levels exceed the EPA/guideline noise limits. Key aspects to include: – program for attended noise measurements – program for unattended noise measurements – proposed weather recording for the period of monitoring – narrow band frequency noise measurements – unattended noise measurements to be conducted for at least seven days • The use of measured data as inputs to updated noise modelling

Air quality

Control design appropriateness	Control modelling and simulation	Monitoring and reporting
• Description of existing air quality data from monitoring that are representative of nearest sensitive receptors and that allow for yearly trends to be determined • Meteorological data that are representative of the conditions across the assessment domain, in a spatial sense. • Topography and land use that influence meteorological and air quality conditions • Explanation of how dust from all sources at the operation will be controlled • Details on dust assessments to demonstrate compliance with dust control guidelines	• Modelling of dust based on standard controls and additional controls to determine whether controls meet the limits.	• Implementation of a dust monitoring plan. Key aspects to include: – program for dynamic dust measurements (for example, mobile monitors) – program for static dust measurements (for example, dust deposition gauges) – proposed weather recording for the period of monitoring

Blasting

Control design appropriateness	Control modelling and simulation	Monitoring and reporting
• Description of blast charge and time delay • Geological structure of the rock • Distances to nearest sensitive receptors • The number of proposed blasts • Description of the type of explosives • Description of the type of mitigation measures	• Include modelling predictions to demonstrate compliance with blasting limits. • Modelling to that includes contour plans at a scale that can be overlaid on imagery or plans of the surrounding area • Influence of atmospheric / meteorological conditions.	• Ground vibration monitoring at specific distances between the source and the sensitive receptor • Comparison of the ground vibration monitoring to with predicted levels

Dams and tailings storage facilities

Control design appropriateness	Control modelling and simulation	Monitoring and reporting
• Compliance with ANCOLD dam criteria • Reference to DEDJTR technical guideline *Management of tailings storage facilities +http://www.energyandresources.vic.gov.au/earth-resources-regulation/licensing-and-approvals/minerals/guidelines-and-codes-of-practice/management-of-tailings-storage-*	• Water balance modelling of site water management system (including dewatering inputs, evaporation facilities, process water demands, makeup water, etc.)	• Monitoring of groundwater (levels and water quality) to ensure that there is no offsite pollution or leakage from water storages • Monitoring of downstream surface water (flow rates and quality) to ensure that there are no uncontrolled releases from site.

Control design appropriateness	Control modelling and simulation	Monitoring and reporting
facilities • Review of appropriate water storage permeability, in relation to site-specific water quality and potential seepage concerns		

Instability

Control design appropriateness	Monitoring and reporting	Control modelling and simulation
• Detailed geotechnical assessment and stability analysis of operational and final landform slopes, possibly including: – evidence that all rehabilitated slopes will not be unduly impacted by ground and groundwater conditions, considering relevant seismic loading and liquefaction, and other factors influencing stability and ground movement. This evidence will rely on limit equilibrium (or finite element) analyses. – justification of assumed design parameters, probably including engineering geological evaluation, laboratory and field testing, rock mass assessment, weathering and erosion, potential for degradation, dispersive process and expansion – historical instability and presence of landslide triggers – previous performance of slopes in similar settings and lithology • The use of appropriate control measures, including (but not limited to): – changed site working patterns – the use of a different method of processing – the use of supporting or reinforcing structures – analysis and submissions as necessary to satisfy all asset owners requirements for any receptor/asset in the GRZ	• Inspections of all areas where slope failures, erosion or sedimentation are likely to occur, including rehabilitated landforms, pit walls, benches and haul roads, drainage lines, discharge points • Monitoring plan for assessment and management of geotechnical and hydrogeological issues (actual monitoring points on plan, and a schedule for measuring these points – prisms, piezometers, extensometers, inclinometers etc.). • Development of a ground control management plan that outlines the management of geotechnical and hydrogeological issues to ensure stability	• Modelling and simulation that could include: – 2D modelling (significant rated activity) – ground movement (strain rates) and dewatering modelling (high rated activity)

Control design appropriateness	Monitoring and reporting	Control modelling and simulation
– development of a surface water management plan describing how surface water diversion and control structures will be designed and maintained to minimise potential for an impact on and recharge to the pit slope materials – a description of the dewatering system and maintenance/monitoring procedures – controls related to subsidence, landslips, toppling, settlement, heave, slumping and fracturing		

Groundwater

Control design appropriateness	Monitoring and reporting	Control modelling and simulation
Describe existing groundwater levels and water quality. – Identify groundwater beneficial use and water quality objectives that are to be protected. – Describe any groundwater extraction or site discharge requirements. – Describe potential groundwater impacts (groundwater quality and level) and sensitive receptors. – Describe control measures to minimise impacts which may include (but not be limited to): – Minimisation of groundwater extraction; – Containment for fuel or chemical storage areas; – Lining of tailings dams; – Collection and treatment of waste rock dump runoff; – Re-injection to maintain groundwater levels. • Design documentation that outlines – proposed remediation techniques for	• The groundwater monitoring plan should document – the application of control measures for groundwater levels and quality – the frequency and type of monitoring – impact assessment review criteria for groundwater level and quality – control failure response actions • The appropriate control measures for groundwater are those that protect the existing groundwater quality and beneficial use, per the objectives and standards for groundwater in the SEPP Groundwater of Victoria and ANZECC water quality guidelines. • The control design should reference minimising impact to beneficial use not exceeding water quality criteria such that remediation is expected to be required. • Monitoring and reporting should be against the appropriate water quality criteria identified in the risk assessment.	• For complex groundwater systems, or where a significant or high risk rating results from the risk review, a groundwater numerical model should be established to assess the potential effectiveness of the proposed controls.The availability of suitable data for model establishment should be incorporated into the risk assessment and data gathering included in the Groundwater Management Plan.

Control design appropriateness	Monitoring and reporting	Control modelling and simulation
any contaminated groundwater – the time that remediation will take – control measures to deal with unplanned events (for example heavy rain during remediation)		

Surface Water

Control design appropriateness	Monitoring and reporting	Control modelling and simulation
• Describe existing surface water quality. • Identify water quality objectives that are to be protected and any site water discharge requirements. • Describe potential surface water impacts and sensitive receptors. • Describe control measures to minimise impacts which may include (but not be limited to): – Minimisation of sediment from erosion; – Management of rainfall runoff; – Collection and treatment of waste rock dump runoff; – Settlement prior to discharge; – Water management during flood events.	• Document in a surface water management plan; – the application of control measures for water quality; – frequency and type of monitoring; – impact assessment review criteria for water quality; – control failure response actions.	• For sites where a significant or high risk rating results from the risk review, a numerical hydraulic model should be established to assess the potential effectiveness of proposed controls. The availability of suitable data for model establishment should be incorporated into the risk assessment and data gathering included in the Surface Water Management Plan.

Appendix 12: Additional control effectiveness rating criteria

Control design effectiveness	Level of control design effectiveness required for significant rated risks	Level of control design effectiveness required for highly rated risks
Control design appropriateness *Is the control design appropriate considering the potential consequences?*	• People-based control – Mature organisation with experienced and skilled workforce, low turnover of staff, clear and documented roles and responsibilities, high level of process discipline with clear process leadership • System-based control – Procedures documented and managed under document control, periodic competency assessment of operators, periodic conformance and outcome evaluation, management reporting	• System-based control – System-initiated control tasks, periodic and system-generated conformance and outcome, system-set rules and protocols, management defined conformance target, continuous conformance and outcome evaluation • Engineering-based control – documented control, training on and understanding of control and control objective, control managed as part of a preventative maintenance system, system generated alarm / notification in the event of failure
Accountability *Is there an accountable owner for the control?*	Control owner is clearly identified and documented (for example, the site manager).	Control owner is clearly identified, and their role and responsibilities are documented (for example, tasks that they should perform in the design, implementation, operation, monitoring and reporting of the control).
Documentation *Are the control's objective, process and limits documented?*	Documentation of the control includes: • an understanding of what the control is attempting to achieve • the relevant limits (for example, under what circumstances/events the control will not work) • process steps relating to, but not limited to, the design, implementation, operation, monitoring and reporting of the control's effectiveness • a hazard and activity register outlining the hazards and risks that the control is seeking to minimise or mitigate • incident reporting (for example, a response process if the control fails). • Escalation process is set for resolving design, implementation, operation and monitoring control issues when relevant entities are unable to agree	All the relevant documentation related to significant rated activities, as well as: • formal periodic reviews of the documentation • a continuous improvement process outlining how learnings are identified, analysed and used to improve the control's performance
Monitoring and reporting *Does the monitoring and reporting program proposed include a clear*	Monitoring and reporting processes are established, but not fully embedded in existing processes, reviews and systems. Monitoring and reporting processes clearly identify:	Monitoring and reporting processes and programs detect non-performance. Performance measures for the control are established, and control documentation is regularly reviewed.

Control design effectiveness	Level of control design effectiveness required for significant rated risks	Level of control design effectiveness required for highly rated risks
management process to assess control effectiveness?	• the impact to be measured • the data to be collected on the impact, and acceptable ranges for the data • relevant thresholds that would apply to monitoring data and actions if thresholds are exceeded • data collection frequency • data collection methods (equipment to be used, by whom, and how calibrated) • monitoring location(s) • reporting frequency, schedule and format.	The monitoring and reporting process includes a continuous improvement processes outlining how the Tenement holder intends to improve control effectiveness and/or reduce the risk. Monitoring and reporting processes clearly state: • the impact to be measured • the data to be collected on the impact, and acceptable ranges for the data • relevant thresholds that would apply to monitoring data and actions if thresholds are exceeded • data collection frequency • data collection methods (equipment to be used, by whom and how calibrated) • monitoring location(s) • reporting frequency, schedule and format.
Competency *Are control owners/ operators competent to operate the control?*	Control owner is directly responsible for executing or maintaining the control, or supervises others that have been assessed as having the necessary knowledge and capability. The level of competency needed to design, implement and operate the control is documented. For significant rated activities, the competency level should be a high level of practical understanding of the hazard/activity control based on several years of experience.	As per significant rated activities. In addition, formal review and performance processes are in place to assess the control operator's competence and ensure they maintain their competence. For high rated activities, the competency level could include tertiary qualifications and/or higher education training, accreditation from a recognised professional industry body, and extensive experience in similar circumstances.
Assurance *Is there an independent assurance process for this control?*	Control will be monitored through an independent assurance assessment (in addition to routine monitoring). Independent assurance assessment will be undertaken by a qualified employee of the Tenement holder who is not directly involved in the site operations or with any direct reporting to the control owner. The appropriately qualified employee will undertake an assurance process to check the control is being operated as designed. The assurance process will involve interviews with the control owner and other relevant stakeholders. Control assurance reports need to be reviewed and endorsed by the Tenement holder, and made available to	Control will be monitored through an independent assurance assessment (in addition to routine monitoring). The independent assurance assessment will be undertaken by a competent person (not directly related to the site) who is suitably qualified in the design and operation of the control. A competent person (not directly related to the site) will undertake an assurance process to check the control is being operated as designed. The assurance process will involve interviews with the control owner and other relevant stakeholders. Control assurance reports need to be reviewed and endorsed by the Tenement holder and made available to the relevant regulator.

Control design effectiveness	Level of control design effectiveness required for significant rated risks	Level of control design effectiveness required for highly rated risks
	relevant regulator.	
Past use of proposed control *Has the control been effective in comparable operating environments?*	Peer reviewed reports describe the effectiveness of the control in comparable situation.	Peer reviewed reports describe the effectiveness of the control in the same application.
Peer review by competent person *Has the control design been reviewed by a competent person?*	A suitably qualified employee of the Tenement holder not directly involved in the operations of the work authority area has completed a peer review of the activity and the suitability of the control, and concludes the control is appropriate and proportional.	A competent person (not directly related to the site) has completed a study assessing the activity and the suitability of the control, and concludes the control is appropriate and proportional. If the proposed technology is new or unusual technology (for example, it has not been previously or extensively used at the site, and has not been used previously under anticipated conditions), the Tenement holder could be subjected to several peer reviews.
Control modelling and simulation *Has the control been tested using different operating assumptions and variables?*	Modelling and simulation of the control are undertaken and results are provided.	Extensive modelling and simulation of the control are undertaken and results are provided. If the proposed technology is new or unusual (for example, it has not been previously or extensively used at the site and has not been used previously under anticipated conditions), the Tenement holder should test the control against a wide range of operating variables and parameters.

Appendix 13: Community engagement plan requirements

According to Schedule 15 of the MRSD(MI)R, a work plan must include a community engagement plan.

Schedule 15 (Part 1) of MRSD(MI)R – community facilities and community engagement plan

"8. A description of the significant community facilities that may be affected by the proposed works.

9. A community engagement plan that –

(a) identifies any community likely to be affected by mining activities authorised by the licence; and

(b) includes proposals for –

(i) identifying community attitudes and expectations; and

(ii) providing information to the community; and

(iii) analysing community feedback and considering community concerns or expectations –

in relation to mining activities authorised by the licence; and

(c) includes a proposal for registering, documenting and responding to complaints and other communications from members of the community in relation to mining activities authorised by the licence."

Section 39A of the MRSDA – licensee's duty to consult with community

"A licensee has a duty to consult with the community throughout the period of the licence by -

sharing with the community information about any activities authorised by the licence that may affect the community; and

giving members of the community a reasonable opportunity to express their views about those activities."

A consultation / community engagement plan is required under clauses 8 and 9 of Schedule 15 of the MRSDM(EI)R. A licensee also has a duty to consult with the community under s39 A of the MRSDA throughout the period of the licence. This consultation provides valuable information that can go into the consultation / community engagement plan.

The consultation / community engagement plan must include:

1. a report cover sheet, including the name, date, author and contact details for the report's author
2. a contents and subheadings for easy assessment and use of the document
3. a brief overview of the proposed operations associated with the exploration licence
4. a brief overview of potential / likely social and environmental impacts of the proposed operations
5. a list of the community and any other stakeholders likely to be affected by the proposed operations, or interested in the proposed activities – including landholders, land owners, local government, community groups and Crown land managers
6. likely community and stakeholder attitudes towards and expectations of the proposed operations
7. how each of the identified community members / stakeholders will potentially be impacted
8. how each of the identified community members / stakeholders will be engaged (and at what level)
9. proposed information channels / types for the community (newsletters / meetings / facilitated events / web content / social media / dedicated contact person etc.)
10. how the community can provide feedback on the operations (online / meetings / phone calls etc.)
11. how community feedback will be captured, registered and responded to (that is, a register or similar that demonstrates how feedback is managed), including an example
12. a description of the proposed complaint / community feedback handling process, including when and how ERR will be notified
13. a timeline for the proposed community engagement, including:
    (a) community / stakeholder groups to be engaged
    (b) how the engagement will take place
    (c) when the engagement will take place

(d) what the engagement will address.

For further information, please see:

1. *Community engagement guidelines for mining and mineral exploration in Victoria* (2008)
2. Code of Practice for Mineral Exploration – Standards, procedures and practical guidance under the *Mineral Resources (Sustainable Development) Act 1990* (2014, section 3 – Community engagement).

Both documents are available on ERR's website at http://www.energyandresources.vic.gov.au/home

Appendix 14: Rehabilitation plan requirements

MRSD(MI)R Schedule 15 **Part 1—Required information—mining work 5 Rehabilitation plan** **5.1 A rehabilitation plan that—**	**Supporting map** **Scale: 1: 2,500 or 1:1,000** **and size: A1 or A2 size preferred**
(a) addresses concepts for the end utilisation of the mine site; and The concept plan should establish expected end use(s) of the site and its general characteristics at the completion of rehabilitation. It may consider: • future land uses that do not depend on the need to obtain a planning permit. If uses requiring a planning permit are being proposed (such as a land fill), the concept plan should be accompanied by a letter from the relevant waste management group. • the capability/suitability of the land – describe the land's inherent features to help demonstrate that the proposed final end use is suitable • possible end land use(s) – provide a conceptual statement on final landform based on all available geophysical, geochemical and biological information • conceptual slope configuration • conceptual rehabilitation of waste dumps, stockpiles, water storages and tailings storage facilities • surface water management for runoff control and erosion prevention • the nature of soils and overburden/waste rock to be used in rehabilitation • evidence that sufficient suitable material is available to complete the proposed final landform. • any constraints on final land use (for example, regulatory constraints, physical constraints, agreements with private land owners) • an overview of proposed action to confirm rehabilitation strategy with relevant stakeholders.	Drawings and plans should show: • North direction, legend, scale, date of/revision date of drawing. • Cross-sections, tenement area boundaries and final pit • Conceptual slope configuration • Proposed final rehabilitated land form • Salient features of the land following rehabilitation (for example, revegetated areas, pit faces, roads, drainage lines and water bodies).
(b) includes proposals for the progressive rehabilitation, stabilisation and revegetation of extraction areas, waste disposal areas, stockpile areas, dams and other land affected by the operation; and *(c) includes proposals for landscaping to minimise the visual impact of the mine site; and* The progressive rehabilitation strategy should detail:	Drawings and plans should show: • Progressive rehabilitation/staging • The progress of rehabilitation over time (for example, topsoil and waste dumps, bunding, final pit faces, benches, areas of landscaping and revegetation, roads, drains

- how a progressive rehabilitation strategy will deliver the final landform / land use outcomes
- how progressive landscaping will be undertaken so visual impact is minimised
- the timeframe between establishing terminal slope and commencing progressive rehabilitation
- the constraints that may limit progressive rehabilitation works
- the approach to undertaking progressive rehabilitation (for example, the availability of suitable material, landscaping, revegetation, the depth of soil stripping, the approximate depth of respread soil, proposed seedbed treatments and the reasons for their selection, the proposed revegetation method, the general mix of species, stockpile dimensions)
- the process for reviewing and improving the rehabilitation plan.

and dams)
- A materials balance

(d) includes proposals for the final rehabilitation and closure of the site, including the security of the site and the removal of plant and equipment, taking into account any potential long term degradation of the environment.

The proposal for the final rehabilitation plan should include:

- whether the proposed final land use is sympathetic to the surrounding landscape (for example, analysis of the visual impact from critical views)
- how the proposed final land form may impact on the long-term surface water/groundwater regime/system
- how final security of the tenement area (for example, water dams/slimes dams etc.) is to be achieved
- the proposed rehabilitation method of any quarry features (slimes dams etc.) to ensure their long-term physical and chemical integrity, including the management of erosion, seepage and potential exposure to contamination
- the proposed general plans for the removal of plant and equipment, including:
  - demobilisation of mobile plant, rolling stock and temporary facilities
  - decommissioning of fixed plant, including the removal and disposal of hazardous materials
  - demolition, refurbishment or reuse of buildings or facilities, including a description of expected waste and disposal methods
- objectives and acceptance criteria to demonstrate achievement of the proposed final land use
- short and long term monitoring and reporting to be undertaken to demonstrate achievement of the final land use.

Appendix 15: Possible statutory referral authority

Catchment Management Authorities (CMA)	Victoria has 10 Catchment Management Authorities, such as Melbourne Water for the Port Phillip region, and the Goulburn Broken Catchment Management Authority for the Goulburn Broken region. Under the Water Act 1989, the local CMA may have an interest and approval requirement for quarries if the proposed quarry area relies on riverine extractions or is situated: on a floodplain (the CMA is the statutory referral authority when a flood or land subject to inundation overlay is present in the local government planning scheme) on or adjacent to a wetland or waterway where CMA contribution to revegetation activities has occurred on relevant land.
Rural Water Authorities (e.g. Southern Rural Water)	Rural Water Authorities implement regulations and policy for groundwater and surface water management, in accordance with delegated powers under the Water Act 1989. These authorities have an interest in mining activities that relates to the intersection with groundwater.
Environment Protection Authority (EPA)	EPA has an interest in mining activities that includes noise, air quality, offsite discharges to water, waste disposal and infill.
Heritage Victoria	Heritage Victoria has an interest in mining activities that includes the potential impacts on state listed historical and archaeological sites (excluding Aboriginal heritage).
Department of Environment, Land, Water and Planning (DELWP)	DELWP has an interest in the possible removal of / impact on threatened species and native vegetation present on and near the mining lease area, if the work authority area is located in a salinity management overlay, impacts on Crown land and its reservation purposes at or adjoining the site.
Council	Council has an interest in mining activities that includes the offsite impacts of mining operations (for example, work hours and offsite traffic during set-up/construction and operation phases).
Other authorities –power (e.g. SP AustNet), **communication** (e.g. Telstra) **and water** (e.g. Yarra Valley Water)	These authorities have an interest in mining activities that include the potential impacts on an easement or asset on or near the work authority boundary.

Appendix D Permeability Results

Soil testing - Determination of permeability of a saturated specimen
Constant head method using a flexible wall permeameter
AS 1289.6.7.3-2016

GOLDER

Test request #:	TRM20-0581	**Lab sample ID:**	LMEL202009047
Client:	EHS Support		
Client address:	Po Box 297, Port Melbourne VIC 3207		
Project ID:	1772660-038-00	**Project reference:**	
Project name:	EHS Support - Permeability Testing		
Project reference:			
Specimen description:	(CI) Sandy CLAY, medium plasticity, black, fine to medium grained sand		

Golder Associates Pty Ltd
MELBOURNE GEOTECHNICAL LABORATORY
Building 7, Botanicca Corporate Park
570 - 588 Swan Street
Richmond, Victoria 3121

Exporatory Hole	**MB7**
Sample depth (m):	37.00
Client sample ref:	-
Location:	-
Phase / Locale:	-
Sample type:	Undisturbed

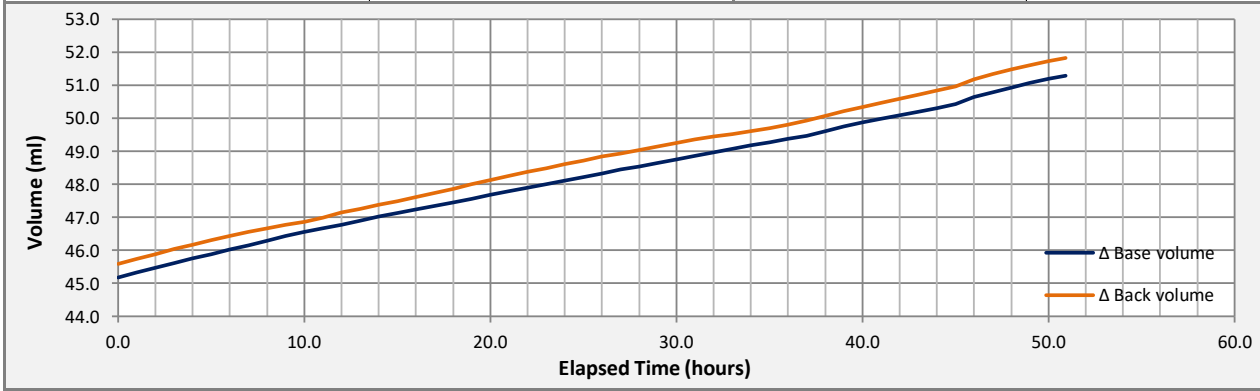
Specimen before testing		Compaction Details	
Height [H] (mm)	63.5	**Method**	-
Diameter [D] (mm)	63.3	**Material retained on 19mm sieve (g):**	-
[D]:[H]	1:1	**Optimum Moisture Content:**	-
Mass (g)	318.2	**Maximum Dry Density (t/m^3):**	-
Moisture Content:	5.3%	**Target moisture content to OMC:**	-
Dry Density (t/m^3):	1.51	**Target dry density relative to MDD:**	-
Assumed Porosity (%)	39.5%	**Laboratory Moisture Ratio:**	-
Assumed Pore Volume (mL)	78.8	**Laboratory Density Ratio:**	-

Pre-test photo

Post-test photo

Permeability test details

Permeant used:	Distilled water
Method of saturation:	Back pressure saturation
Estimate of initial saturation:	20.4%
Saturation B value:	98%
Confining Pressure (kPa):	2212
Inlet Pressure (kPa):	1805
Outlet Pressure (kPa):	1795
Mean effective stress (kPa):	412
Hydraulic Head (kPa):	10
Moisture content after test:	22.7%
Permeability: (m/s)	**7E-10**



Notes: Specimen prepared from a u63 tube sample, subsampled from a larger undisturbed core sample provided by client

Definitions:	**Specimen Prepared by:**	LM	**Test Performed by:** LM
ND = Not Determined	**Results Reviewed by:**	NLobb	**Date Reported:** 30/09/20

Cert. Ref.: 1772660-038-001_MB7_2009047_TRM20-0581_PERM_R20057065 **Approved Signatory:**

Appendix D 6-Month Pumping Test Outcomes

The long-term pumping test is an important component of the overall mine water strategy. The pumping test observations and analysis allow for understanding aquifer behaviour, constraining long-term sustainable pumping rates, and evaluating risks to receptors or environmental values. This section outlines:

- The adopted trigger levels and contingency measures to manage potential risks during the pumping test.
- The pumping test methodology.
- The observations and outcomes from the first 6-month groundwater pumping test.
- The derived UEVF aquifer hydraulic parameters (i.e., storativity and transmissivity).

D.1 Aquifer Pumping Test Methodology

The principle of a pumping test involves applying a stress to an aquifer by extracting groundwater from a well and measuring the aquifer response to that stress by measuring drawdown as a function of time. The measurements are incorporated into an appropriate well-flow equation to calculate the hydraulic parameters of the aquifer.

D.1.1 Objectives

The overall objectives of the aquifer pumping test (13 May 2021 to 8 December 2021) are to:

- Obtain additional hydrogeological data that can be used to develop a robust and peer-reviewed conceptual and numerical groundwater flow model that will determine if the use of longer term UEVF groundwater is a practical and an environmentally sustainable water management strategy to fill the mine pit void as part of the MRCP.
- Address data gaps identified in the draft MRCP.

To achieve these objectives the following was undertaken:

- Derive UEVF aquifer hydraulic parameters (i.e., storativity and transmissivity) to support the refinement of a numerical groundwater flow model by monitoring the aquifers response to pumping in surrounding observation bores.
- Update a CSM within the vicinity of the coal mine and former power station to inform localised refinement of an existing numerical groundwater flow model, as well as a risk assessment.

Following the completion of the first six-month pumping test, the revised numerical groundwater flow model will be used to determine a long-term sustainable pumping rate that can be used to help accelerate the filling of the water body (GHD 2022 (DRAFT)). In this event Alcoa proposes to seek a long-term groundwater license amendment from SRW to support the filling of the mine void.

After an approximate three-month cessation period, groundwater extraction will then resume for another six months. This period of pumping is expected to:

- Provide further validation of the numerical groundwater flow model calibration and predictions and the associated risk assessment; and
- Provide additional confidence to the community and key stakeholders.

D.1.2 Aquifer Pumping Test Program

The aquifer pumping test program included several stages to understand responses to aquifer stress as summarised in **Table D-1**.

Table D-1 Aquifer Pumping Test Program

Activity	Date
Installation of DBG MB1 – MB8 and UEVF MB1 – MB8	27 August 2020 to 30 April 2021
Baseline monitoring period – water level observations	10 December 2020 to 13 May 2021
Baseline monitoring period – groundwater quality sampling	8 – 12 & 23 April 2021
Pumping Test – 40 L/sec	13 May 2021 to 8 June 2021 and 6 August 2021 to 8 December 2021
Pumping Test – 50 L/sec	8 June 2021 to 6 August 2021
Pumping test recovery monitoring	From 8 December 2021 ongoing

D.1.3 Pumping Bore Specification

Groundwater was extracted from WB16 during the entire pumping test. The pumping infrastructure was installed and maintained by Agmek Ballarat Pty Ltd and is shown on **Photo 6-1** and **Photo 6-2**.

Photo 6-1 WB16 Pumping Bore Setup

Photo 6-2 WB16 Sampling Point and Flow Meter

The construction details of the pumping bore WB16 are summarised in **Table D-2** and the bore log is presented in **Appendix F**. The pumping bore has multiple screened intervals that all intersect the deeper zone of the UEVF. The bottom of the pumping bore is understood to be located at the base of the UEVF (i.e. where it intersects the MEVF).

Table D-2 Pumping Bore WB16 – Well Construction Summary

Casing From (mbgl)	Casing To (mbgl)	Casing ID (mm)	Casing Type and Material
0	163.7	307	Fibre glass reinforced plastic casing
163.7	173.7	203	Mild Steel
173.7	177.8	203	Wire-wound stainless-steel screen, 1.0 mm slot
177.8	183.7	203	Fibre glass reinforced plastic casing

Table Notes:

mbgl – metres below ground level

D.1.4 Groundwater Extraction Rate and Discharge

Groundwater extraction commenced on the 13 May 2021 at 11:00am. A summary of the extraction rates and duration is summarised in **Table D-3**.

Table D-3 Groundwater Extraction Rate Summary

Pumping Rate (L/sec)	Pumping Dates	Duration (hours)
40	13 May 2021 to 8 June 2021	630
50	8 June 2021 to 6 August 2021	1,412
40	6 August 2021 to 8 December 2021	2,970

The pumped groundwater was transferred via pipe to the mine pit void where it was discharged below the current mine water level, refer **Photo 6-3** and **Photo 6-4**. This mitigated contact to atmospheric oxygen as well as potential erosion.

Photo 6-3 Discharge Pipe

Photo 6-4 Discharge Location

D.1.5 Pumping Test Groundwater Monitoring Network

Of the 130 catchment wide monitoring bores, 31 (including the 4 Barwon Water bores) were selected to act as dedicated monitoring or nominated trigger bores for the pumping test. These bores are shown in above, and their construction details summarised in **Table D-4**. The pumping test groundwater monitoring network also incorporated the broader monitoring network Barwon Water use for their monitoring and assessment program (MAP), part of their monitoring requirements for their Bulk Entitlement.

Table D-4 Pumping Test Monitoring and Trigger Bores

Bore ID	Aquifer Monitored	Screen Interval (mbgl)	Trigger Bore (T) or Monitoring Bore (M)	Rationale
DBG MB1	Boonah Formation	37 – 40	M	These monitoring bores are located spatially around the periphery of the mine pit void located as close as practical and in a safe to access area. The monitoring objective of these bores are to confirm the presence and behaviours of any groundwater within the Boonah Formation and Mine Overburden. If during the 12-month pumping test the mine pit water level reaches -15mAHD, the pit water has the potential to migrate into the Boonah Formation.
DBG MB2	Boonah Formation	60 – 63	M	
DBG MB3	Boonah Formation	69 - 72	M	
DBG MB4	Mine Overburden	35 – 38	M	
DBG MB5	Mine Overburden	18 – 21	M	
DBG MB6	Mine Overburden	34 – 37	M	
DBG MB7	Boonah Formation	8 – 11	M	
DBG MB8	Boonah Formation	28 – 31	M	
MW27	Boonah Formation	10 -15	M	These bores are located in close vicinity (<250 m) around the pumping bore and screened in either the shallow DBF (PWTa) or the Boonah Formation associated with the surface water systems. These bores are also located as far away as practical from former power station assets such as the water reclamation pond which may influence water levels. MW27, MW29 and MW33 are also located adjacent to Marshy Creek. Monitoring of these bores was
MW29	Boonah Formation	6 – 12	M	
MW33	Boonah Formation	8 – 14	T	
MW37	DBF (PWTa)	3 – 6	M	
MW64	Boonah Formation	7 – 13	T	

Bore ID	Aquifer Monitored	Screen Interval (mbgl)	Trigger Bore (T) or Monitoring Bore (M)	Rationale
				undertaken to understand potential surface water / groundwater interactions.
UEVF MB1	$UEVF_U$	92 – 98	M	These monitoring bores are located spatially around the periphery of the mine void located as close as practical and in a safe to access area. The objective of these bores are to monitor for potential drawdown caused by pumping. If drawdown does occur, it increases the potential for mine water to seep into the aquifer. UEVF MB8 exhibits a higher groundwater elevation than the other bores in the upper section of the UEVF (MB1 – MB7). The higher groundwater level seen in this bore is likely representative of the confining coal and clay in which the bore is screened. During drilling, no upper sands were observed in this bore (as was observed in MB1 to MB7) apart from a possible 10-20cm lens located at approximately 82 mbgl in which the bore was screened.
UEVF MB2	$UEVF_U$	122 – 128	M	
UEVF MB3	$UEVF_U$	139.3 - 145.3	T	
UEVF MB4	$UEVF_U$	71 – 77	M	
UEVF MB5	$UEVF_U$	59 – 65	T	
UEVF MB6	$UEVF_U$	69 – 75	M	
UEVF MB7	$UEVF_U$	42 – 51.6	T	
UEVF MB8	$UEVF_U$	81 – 84	M	
WB4	$UEVF_L$	108.2 – 195	M	These bores are either former power station production or observation bores. They are screened in the lower part of the UEVF and will monitor drawdown as a result of pumping. The data will be used to provide reliable hydraulic parameters for a future numerical groundwater flow model.
WB12	$UEVF_L$	147.2 – 221.3	M	
WB14	$UEVF_L$	155.9 - 213.7	T	
WB15	$UEVF_L$	186.8 - 247.5	M	
WB16	$UEVF_L$	173.7 – 220.2	PB	This is the Pumping Bore.
116459	$UEVF_L$	243 - 246	T	This is a State observation bore with a long history of water level data. Drawdown observations within this bore will be used to ensure drawdown does not exceed what was modelled in the GIA and thus potential risks to environmental assets in outcrop areas remain low.
P8	ASA	0.36 – 2.73	M	These bores form part of the Barwon Water monitoring network. These were monitored by Barwon Water during the pumping test.
P12	LEVF	18 – 21	M	
P17	ASA	0.3 – 5.4	M	
P19	UEVF	19 – 22	M	
SB2	UEVF	223 - 226	M	

Table Notes:

mbgl – metres below ground level

$UEVF_U$ = Upper Sands of the UEVF

$UEVF_L$ = Lower Sands of the UEVF

D.1.6 Monitoring Activities and Elements

Monitoring activities varied from general site observations to in-situ water level measurements and sample collection for laboratory analysis. The level (type and frequency) of monitoring was established to assess changes in groundwater and the mine pit void water body.

D.1.7 Groundwater Level Monitoring

As discussed above and shown on **Figure 2-2** groundwater monitoring locations have been established by Alcoa and Barwon Water within the DBF (PWTa), Boonah Formation, UEVF (upper and deeper zone) and LEVF. During the baseline period and throughout the pumping test, continuous (hourly) groundwater pressure monitoring was recorded in all nominated monitoring and trigger bores, including by Barwon Water for those owned by Barwon Water (bores P8, P12, P17, P19 and SB2).

Groundwater level monitoring was collected using two primary data collection methods:

- Continuous monitoring using Solinst Levelogger.
- Manual gauging prior to each groundwater sampling event, undertaken monthly.

A Solinst barometric pressure transducer, in the vicinity of the Alcoa office, logged fluctuations in barometric pressure. The barometric data was used to correct groundwater pressures for the effects from barometric pressures and used to calculate the groundwater elevation.

D.1.8 Mine Pit Water Level Surveying

The mine pit water level has been surveyed by an independent surveying contractor (Cardno TGM) since June 2020. The survey point is along the south mine face and is shown on **Figure 2-2**. The mine pit water level since the commencement of pumping is shown on **Figure D-8** below.

D.1.9 Groundwater and Mine Pit Void Sampling Program

Mine pit void water body and groundwater sampling was conducted in accordance with the requirements of publication Victorian EPA (2009). All identified Alcoa owned monitoring bores and trigger bores that form part of the monitoring network (refer to **Section 6.2.5**) were sampled using a submersible pump and collected in laboratory supplied bottles and sent to a National Association of Testing Authorities (NATA) accredited laboratory for analysis. Groundwater sampling of Barwon Water monitoring bores was not undertaken. Grab samples were taken from WB16 where pumping was under continuous operation. In-situ field parameters were also measured at the time of sampling.

The sampling was undertaken in accordance with the schedule shown in **Table D-5**. Sampling was conducted in accordance with QA/QC procedures outlined in *EHS Support (August 2021) 12-month Groundwater Pumping Test Monitoring Plan – Anglesea Power Station and Coal Mine*. The analytical suite is shown on **Table D-6**.

Table D-5 Adopted Sampling Program

D.2 Baseline Groundwater Levels

Prior to conducting the pumping test, baseline conditions were monitored for approximately five months to evaluate static groundwater conditions. The following section discusses the evaluation of water levels, and pressure transducer data to establish baseline conditions.

D.2.1 Potentiometric Surface

D.2.2 Demons Bluff Formation

A total of 37 groundwater monitoring bores have been installed across the former power station site, and 8 groundwater monitoring bores installed across the Alcoa coal mine site targeting the DBF (mostly screened in the Boonah Formation). Of these monitoring bores, 13 were incorporated in the pumping test monitoring program. The baseline elevation (as of 17 November 2021) of the water table of this unit is shown on **Figure 5-39**.

Groundwater conditions at the Alcoa coal mine indicate that the DBF nearer the coal mine is largely unsaturated. For the saturated DBF bores located nearer the former power station, groundwater levels generally fall within the -4 to +4 m AHD range, which was the same range previously reported for the unconfined aquifer prior to Alcoa development (Hancock, 1967). This, combined with the absence of any widespread increases in DBF groundwater levels since Alcoa groundwater extraction from the UEVF aquifer ceased in 2016, indicates that past site activities, such as groundwater extraction from the UEVF or mine dewatering, are unlikely to have resulted in significant decreases in water levels within the DBF aquifer.

The direction of groundwater flow is expected to follow topography as well as being influenced by the mine pit void.

D.2.3 UEVF Upper Sands

An upper permeable sand unit within the UEVF was recorded in close vicinity to the Alcoa coal mine, noting that this unit pinches out along the western embankment of the mine pit void. Eight groundwater monitoring bores were installed in this unit in 2020/2021 and form part of the pumping test monitoring program.

The upper sands of the UEVF forms a discontinuous permeable unit that is separated from the shallow Boonah Formation by the basal clay and main coal seams. The direction of groundwater flow is expected to follow topography as well as being influenced by the mine pit void (**Figure 5-59**).

D.2.4 UEVF Lower Sands

At the site, the UEVF lower sands are confined by greater than 100 m of coal and clay that separate these sands from shallower permeable units (refer to sections above for lithological relationship between these two units).

A number of dewatering bores were installed by Alcoa across the former power station site targeting the lower sands of the UEVF to facilitate mining operations. Five of these dewatering bores form part of the pumping test monitoring program; the remainder of these dewatering bores have been decommissioned for various reasons.

Static groundwater elevations from May 2021 (i.e., prior to the commencement of the 12-month pumping test) indicate greater hydraulic pressures in the lower sands of the UEVF compared to the overlying upper sands (**Figure 5-62**).

D.2.5 Hydrographs

Hydrographs of monitoring and trigger bores during the baseline period are provided as **Figure D-1** to **Figure D-3**. Groundwater bores screened with the upper and lower sands of the UEVF show generally increasing groundwater elevations throughout the baseline period (**Figure D-1** and **Figure D-2** respectively). Groundwater bores screened within the Boonah Formation/DBF show a static response with minimal influence from direct rainfall recharge (**Figure D-3**).

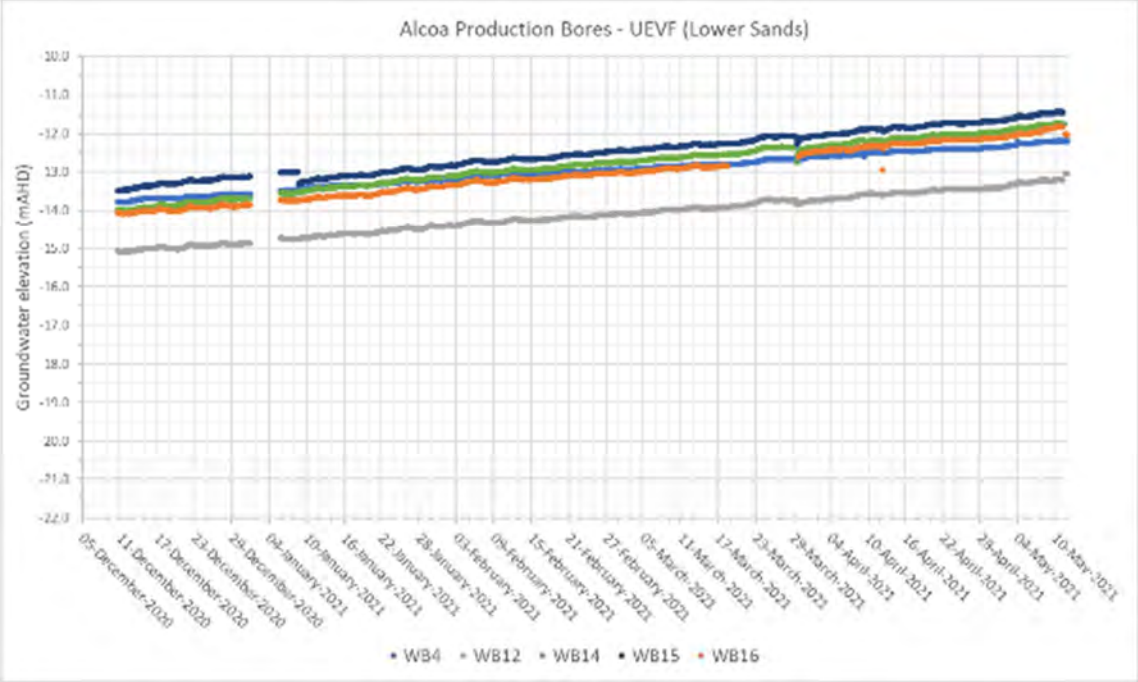

Figure D-1 UEVF (Lower Sands) Alcoa Production Bores – Baseline Groundwater Elevations

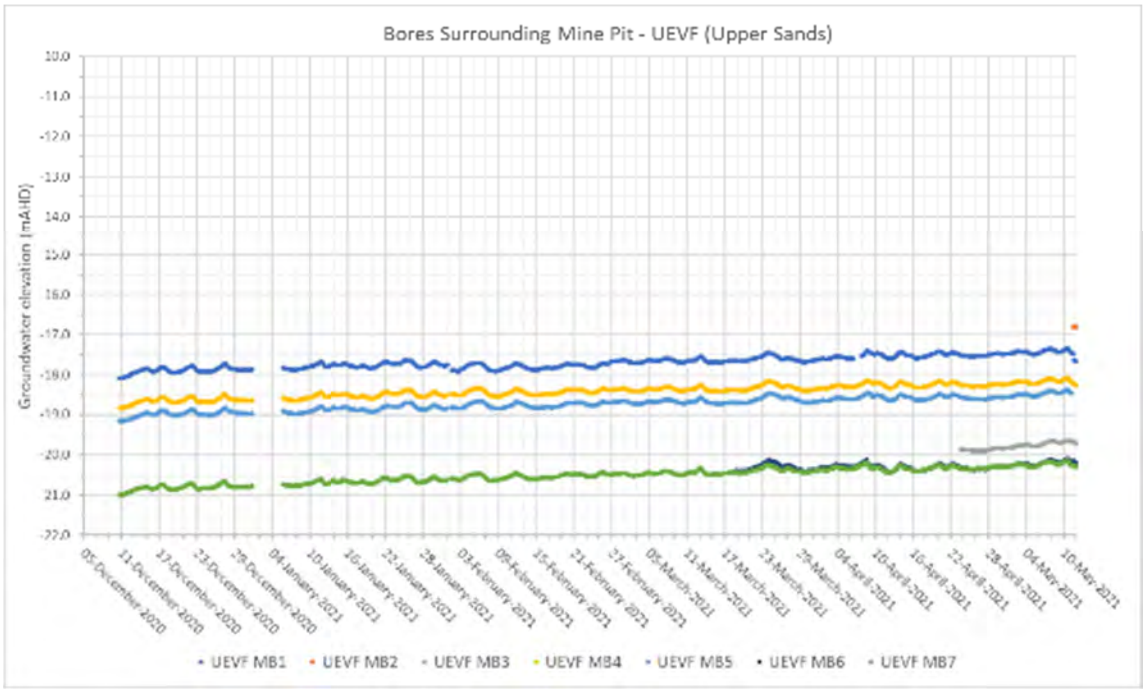

Figure D-2 UEVF (Upper Sands) Bores Surrounding Mine Pit – Baseline Groundwater Elevations

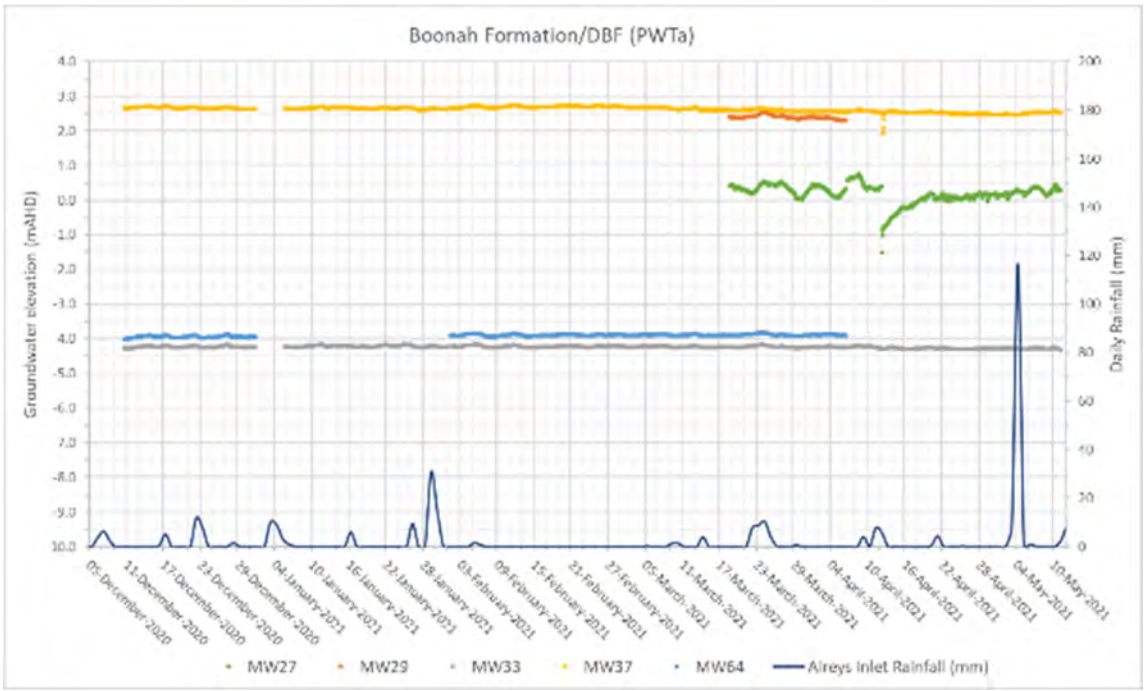

Figure D-3 Boonah Formation/DBF (PWTa) Bores – Baseline Groundwater Elevations

D.3 First 6-month Pumping Test Results

As noted in **Section 6.3.1** above, the main objective of the first 6-month pumping test was to derive UEVF aquifer hydraulic parameters to support the refinement of a numerical groundwater flow model and to update the CSM as well as the risk assessment based on the groundwater pressure and water quality observations during the test.

Groundwater is extracted from the aquifer and regulated to maintain a constant uniform rate during a constant rate pump test. The pressure response within the pumped bore and surrounding bores are monitored during the drawdown phase and during the subsequent recovery period to provide a means for estimating hydraulic and storage properties of the aquifer as well as for discerning formational and non-formational flow conditions (i.e., boundary effects).

The pumping test was conducted from 13 May 2021 to 8 December 2021 at WB16. The constant rate pumping test had a pre-selected pumping rate of 40 L/sec based on specific drawdown/discharge characteristics exhibited during the previous 7-day constant rate pumping test undertaken in April 2020, and historical Alcoa dewatering pumping rates. The pumping test commenced at 40 L/sec for a period of approximately 26 days and then was increased to 50 L/sec for an additional 59 days. Based on the drawdown observations, the pumping rate was reduced back to 40 L/sec for the remainder of the pumping test (124 days). Discharge was monitored using a calibrated magnetic flow meter at WB16, and groundwater was discharged to the mine pit void. Groundwater recovery has been monitored since the pump was turned off on the 8 December 2021.

The data analysis approach to the pumping test is based on type-curve matching methods commonly used to analyse standard pumping test responses.

D.3.1 Methodology and Design

The pumping test was monitored in the pumping bore WB16 and 26 monitoring bores. The depth to groundwater (and subsequent calculation of groundwater elevations) was recorded by a pressure transducer at 1-hour intervals and measured manually monthly to ensure that the flow rate and drawdown was satisfactory for the test. The pump flow-rate was logged electronically by the magnetic flow meter and checked regularly during the pumping test. The pressure transducers have been left in the monitoring bores to record groundwater recovery following the cessation of pumping on the 8 December 2021. A barometric pressure logger is located at the site and used to compensate all datalogger data for atmospheric pressure changes.

Table D-7 summarises the pumping and recovery test program.

Table D-7 Summary of Pumping Test

Phase	Start	Finish	Duration (hours)	Flow Rate (L/sec)	Max. Observed Drawdown / Recovery (m)
Pumping	13/08/2021 11:00 pm	08/12/2021 08:00 am	5,013	40 to 50	64.66
Recovery	08/12/2021 08:00 am			NA	

Table Notes:
L/sec - litres per second
m - metre

During the pumping test, drawdown versus time from WB16 was plotted on a semi-logarithmic plot and updated as new data was collected. Projections of drawdown were made as the test proceeded and compared with measured results. The plot assists in identifying boundary effects and other hydraulic features. When field data curves of drawdown versus time deviate from theoretical curves of the main types of aquifer, the deviation is usually due to specific boundary conditions (e.g., change in aquifer transmissivity and storativity, well bore storage, recharge boundary, impermeable boundary, geological boundaries, extraction of groundwater elsewhere).

D.3.2 Monitoring and Recovery

Field activities conducted during the pumping test included the following:

- Manual gauging of groundwater levels prior to, during and after the pumping test in the monitoring bore network.
- Manual gauging of groundwater levels monthly during the pumping test to supplement the datalogger data and verify groundwater elevations.
- Automated measurement of groundwater levels using pressure transducers.
- Discharge monitoring via a magnetic flow meter supplied by Agmek Ballarat Pty Ltd.
- Management of extracted groundwater to the mine pit void.
- Monthly sampling of the monitoring network and mine pit void.

D.3.3 Data Analysis

A range of analytical solutions were initially applied to the pumping test data using Aqtesolv™ (HydroSOLVE, Inc.). Diagnostic flow plots (i.e., radial flow) and derivative analysis (Bourdet et al. 1983; Bourdet et al. 1989) are tools used to facilitate and strengthen the interpretation of the pumping test data. A plot of linear drawdown (s) against log time (t), also referred to as a Jacob plot, was undertaken to identify the category of aquifer and the pattern of behaviour. Such plots inform if the system is confined or unconfined, has delayed yield, or exhibits leakage properties.

Based on the findings of the preliminary analysis, appropriate solutions can be applied to derive aquifer and aquitard characteristics such as transmissivity, hydraulic conductivity, storativity, and leakage coefficients. The Papadopulos-Cooper (1967) solution was adopted for this analysis to estimate the transmissivity and storativity of the UEVF lower sands aquifer.

D.3.4 Pre- Pumping Test Groundwater Levels

Prior to commencing the pumping test, the monitoring bore network was manually gauged on 11 May 2021. The recorded groundwater levels are summarised in **Table D-8**.

Table D-8 Pre- Pumping Test Groundwater Levels

D.3.5 Rainfall and Barometric Pressure

Approximately 431 mm of rain (Aireys Inlet BoM Station 90180) fell during the pumping test. Rainfall prior to and during the test period was considered in the pump test evaluation and barometric pressure changes were compensated for in the analysis of the transducer data.

D.3.6 Pumping Bore WB16 Groundwater Level Response

The pumping test was initiated on 13 May 2021 at 11:00am. As discussed above the starting pumping rate was 40 L/sec. At 5:00 pm on 8 June 2021 the pumping rate was increased to 50 L/sec. Following the temporary increase in the pumping rate, the pumping rate was adjusted back to 40 L/sec at 2:00 pm on 6 August 2021 for the remainder of the pumping test. The test was terminated at 08:00 am on 8 December 2021. A total volume of 671.9 ML was discharged to the mine pit void.

Water level response at WB16 during the pumping test indicated a maximum drawdown of 64.66 m was achieved at the pumping bore, and a drawdown of 51.94 m was recorded at the end of the pumping test. Following pump shutdown, groundwater levels in WB16 initially recovered rapidly. Recovery was within about 90% of initial groundwater levels after 30 days (i.e. with 5.7 m of static levels).

A plot of drawdown and recovery versus time at WB16 is displayed on **Figure D-4**. It is noted that during the entire duration of the pumping test, the pump intermittently shut off either due to malfunction or for maintenance activities. These shut down periods can be seen in the plot where groundwater levels start to recover.

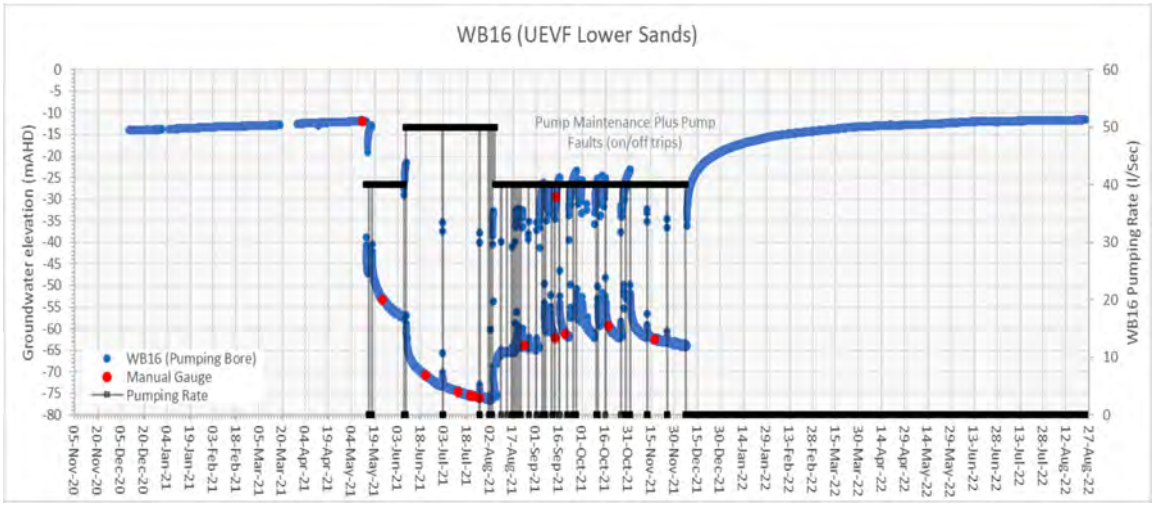

Figure D-4 Plot of Drawdown and Recovery at WB16 Versus Time

D.3.7 Monitoring Bore Network Groundwater Level Response

Groundwater level changes during the pumping test across the monitoring network are presented in **Figure D-5** to **Figure D-9**.

As expected, a drawdown response is observed in the Alcoa production bores screened in the lower sands of the UEVF (**Figure D-5**). SOB 116459 is screened within the lower sands of the UEVF and does not show a response to groundwater pumping (**Figure D-6**). This bore is located approximately 2.5 km from WB16. Barwon Water monitoring bore SB2 is screened within a 3 m section at the base of the lower sands of the UEVF. This monitoring bore is located approximately 1 km to the south of WB16 and recorded a response during pumping (**Figure D-7**).

Groundwater bores screened within the Boonah Formation/DBF (PWTa) do not show a response to the pumping test. Groundwater bores screened within the upper sands of the UEVF also do not show a response to the pumping test, with groundwater elevations continuing to increase as noted during the baseline period (**Figure D-8** and **Figure D-9** respectively).

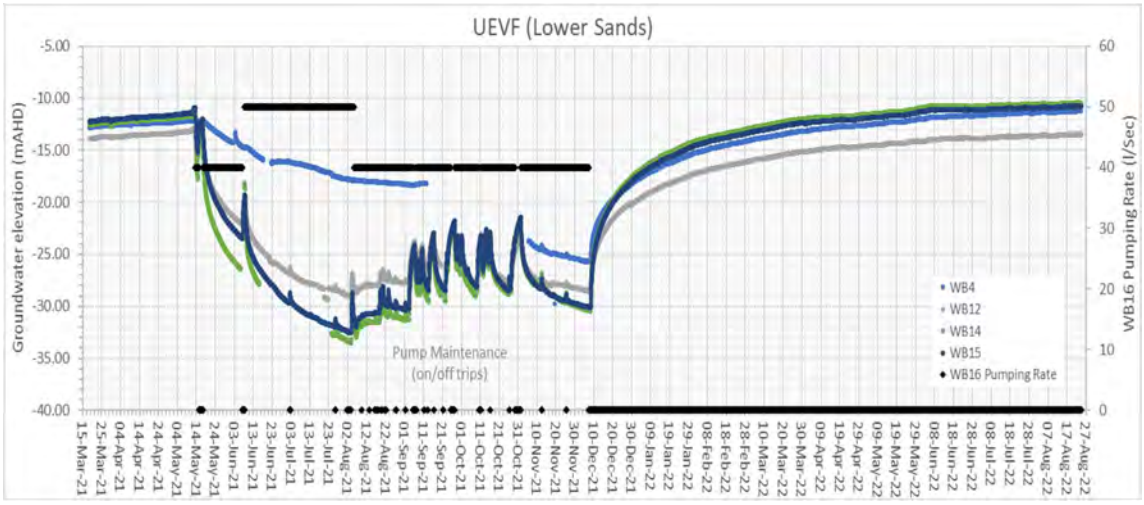

Figure D-5 UEVF (Lower Sands) Alcoa Production Bores – Plot of Drawdown and Recovery Versus Time

Figure D-9 Boonah Formation/DBF (PWTa) Bores – Plot of Drawdown and Recovery Versus Time

D.3.8 Distance Drawdown Analysis

The lithology of the UEVF lower sands aquifer comprises a series of alternating lenses (between 1 and 10 m) of high permeability sands and thicker alternating lenses of lower permeability silts/clays and coals. The Alcoa production bores monitored during the pumping test were constructed with a focus on intersecting these more permeable sands, and in some cases have six or seven screened sections ranging in length from 2 to 7 m, over a saturated thickness of approximately 75 m (i.e. the saturated thickness of the UEVF lower sands aquifer). Some of these production bores however may have intersected and screened the upper 5 m section of the MEVF aquitard. The Barwon Water monitoring bore SB2, however was constructed to intersect a 3 m permeable section only, at the base of the UEVF lower sands aquifer (i.e. screened from 223 – 226 mbgl).

The drawdown response observed at these monitoring bores at a distance from the pumping bore is a function of a number of factors, and lithological uncertainties, such as:

- Are the sand lenses screened at WB16 laterally equivalent across the catchment?
- Do the other observation bores screen the same sand lenses as those at WB16?
- Are some of these sand lenses drained during the pumping period?
- Are some of the sand lenses more permeable than others?
- Are the alternating lenses of lower permeability silts/clays/coals providing leakage across the aquifer?

The drawdown response in an observation bore(s) is used to derive aquifer hydraulic parameters. Therefore if any of the factors above are controlling the drawdown responses at the observation bores, which they likely are, they may also impact the derivation of transmissivity and storativity. Unfortunately the aquifer solution methods used to derive transmissivity and storativity can't account for these factors, and have a number of inherent assumptions and limitations, such as the aquifer is homogenous, isotropic and of uniform thickness, and the aquifer has infinite aerial extent.

A summary of the drawdown recorded at the pumping bore, and closest monitoring bores screened in the lower sands of the UEVF, calculated at different time intervals during the pumping test are provided in **Table D-9**.

The drawdown recorded at WB14 (228 m from WB16), WB15 (371 m from WB16) and SB2 (1,060 m from WB16) after approximately 2-3 months of pumping display a similar extent, and this trend is observed until the end of the 6-month test, indicating that the cone of depression may have reached a steady state. The responses in these three monitoring bores appear to be reflective of the aquifer and are considered suitable for analysis.

WB12 is located adjacent to the pumping bore and showed a subdued drawdown response. Subsequent bore investigations (down-hole camera survey) identified issues with the well casing and well screens. Therefore the data collected from WB12 is not considered appropriate for analysis.

Monitoring bore WB4 was re-sleaved during the pumping test as well casing issues were also highlighted. These investigations and rectification works occurred between July and October 2021. Therefore the data collected from WB4 is not considered appropriate for analysis. However the rectifications works mean that this bore is suitable for future and ongoing monitoring purposes.

Table D-9 Drawdown and Recovery During Pumping Test

Bore ID	Distance from WB16 (m)	Drawdown (m)				Recovery (m)	% Recovery
		1 month	3 months	6 months	End of test	After 1 month	
WB16	0	56.10	53.38	49.51	51.94	46.27	89
WB12	28	10.75	15.11	14.65	15.70	9.55	61
WB14	228	15.28	19.90	16.48	18.39	14.22	76
WB15	371	14.55	19.80	17.27	19.04	13.50	70
WB4	442	3.14	5.90	12.37	13.59	8.65	64
SB2	1,060	11.34	19.46	16.14	18.47	11.52	62

D.3.9 Groundwater Quality

The mine pit void and groundwater monitoring network, including the pumping bore, were sampled prior to the commencement of the pumping test (i.e. baseline) and monthly during the pumping test in accordance with the schedule and analytical suite outlined in **Table D-5** and **Table D-6** respectively.

Total dissolved solids (TDS), ion ratios (i.e. Cl/Br and Cl/B) and dissolved metals trends were evaluated to assess whether mine pit void seepage and groundwater mixing may be occurring as a result of filling the mine pit void with groundwater. **Figure D-10** to **Figure D-13** present the major ion ratios across the monitoring network. These ratio plots indicate that groundwater quality across the entire monitoring network has not changed significantly from baseline conditions, apart from minor variations likely associated with climatic conditions, and mine pit water is not migrating into the upper sands of the UEVF and/or the Mine Overburden/Boonah Formation/DBF (PWTa).

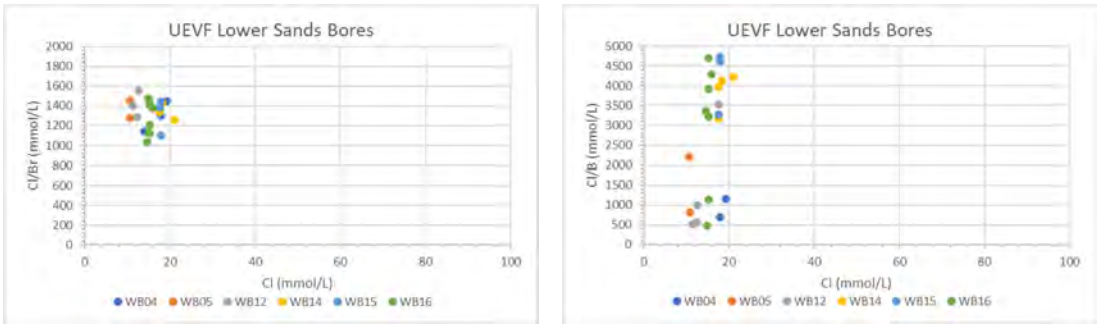

Figure D-10 Cl/Br vs Cl and Cl/B vs Cl Ratios – UEVF (Lower Sands) Alcoa Production Bores

Figure D-13 Cl/Br vs Cl and Cl/B vs Cl Ratios – Mine Pit Water

D.4 Aquifer Pumping Test Interpretation

D.4.1 Diagnostic Flow Plots

The time-drawdown relationship for WB16 was plotted using a log-linear (i.e., semi-log) plot to assess the indicative aquifer conditions (**Figure D-14**). The plot was found to be uncharacteristic of the theoretical time-drawdown relationships for confined, unconfined and leaky unconsolidated aquifers, however the early time data approximately resembles a confined aquifer type and this is consistent with expectations based on geology (Kruseman and de Ridder 2000).

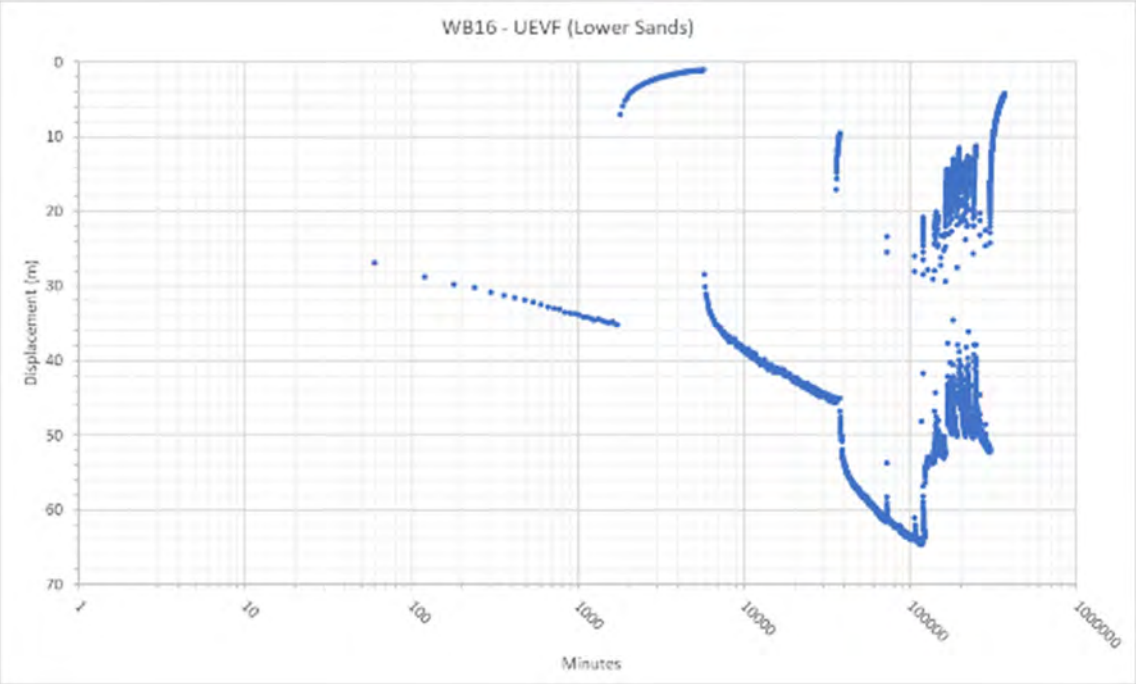

Figure D-14 Semi-Log Plot of Time-Drawdown Relationship (WB16)

Radial flow plots were evaluated to assist in identifying radial flow behavior or well bore storage. Due to the intermittent pump stoppages throughout the 6-month test, unit slope analysis on the early (well bore storage characteristics) and late (infinite acting radial flow) time data could not be characterised. However, the drawdown data across the monitoring bore network does not indicate that local boundary conditions were encountered during the test, such as dykes or geological boundaries where the drawdown in observation bores adjacent to these features would be greater than that observed at other spatial distributed observation bores at an equal distance from the pumping bore.

It was observed that the drawdown at SB2 located 1,060 m from WB16 is roughly equal to that of drawdown recorded at WB14 and WB15 located approximately 300 m from WB16. This may indicate that the cone of depression may have reached a steady state or that preferential flow pathways exist to the south towards the coastline, the former the most likely scenario.

D.4.2 Solution Matching and Aquifer Parameters

The Papadopolus-Cooper (1967) solution was adopted for analysis to determine the transmissivity and storativity of the UEVF lower sands aquifer. Aqtesolv™ (HydroSOLVE, Inc.) was used as the modelling platform. Outputs from the analysis are provided in **Appendix G**.

The following assumptions were adopted in the modelling, and limitations identified:

- The pumping bore WB16 fully penetrates the aquifer.
- Monitoring bores WB14 and WB15 fully penetrate the aquifer.
- Monitoring bore SB2, partially penetrates the aquifer.
- Solution methods for pumping tests assume one continuous screen length. It is noted that WB14, WB15 and WB16, that fully penetrate the aquifer, have segregated screened intervals at varying depths.
- Aquifer thickness of 72 m was adopted based on the bore logs from WB16 and SB2.
- A Kv/Kh ratio of 0.1 was adopted.
- The solution method accounts for well bore storage.

A number of different analyses were undertaken, selecting different observation bores for analysis, to derive aquifer hydraulic properties. This approach was adopted to account for the heterogeneity of the aquifer formation (i.e. alternating lenses of high and low permeability unconsolidated material), uncertainty around the lateral continuity of the higher permeable sand lenses, and the potential for the production bores to be partially screened in lower permeable lenses or underlying formations. This approach provides for a range of hydraulic parameters, that can be used as preliminary input parameters for the numerical groundwater flow model.

Based on the analyses, the estimated transmissivity ranged from 58.2 to 114.2 m^2/day (hydraulic conductivity range of 0.8 to 1.6 m/day) and a storativity range of 2 x 10^{-4} to 5 x 10^{-4} (**Table D-10**). The tight, deep drawdown curve observed at WB16 is representative of aquifers of low transmissivity. These derived parameters are also consistent with previous estimates (GHD 2013, EHS Support, 2018, EHS Support, 2019).

Table D-10 Derived Hydraulic Properties

Observation bores active during solution matching	Transmissivity (m^2/day)	Hydraulic Conductivity (m/day)	Storativity
WB14, W15, SB2 and pumping bore WB16	111.7	1.5	2 x 10^{-4}
WB14, W15, SB2 only	88.6	1.2	5 x 10^{-4}
WB14 only	114.2	1.6	3 x 10^{-4}
WB15 only	84.5	1.2	5 x 10^{-4}
SB2 only	58.2	0.8	3 x 10^{-4}
Average	**91.4**	**1.3**	**4 x 10^{-4}**

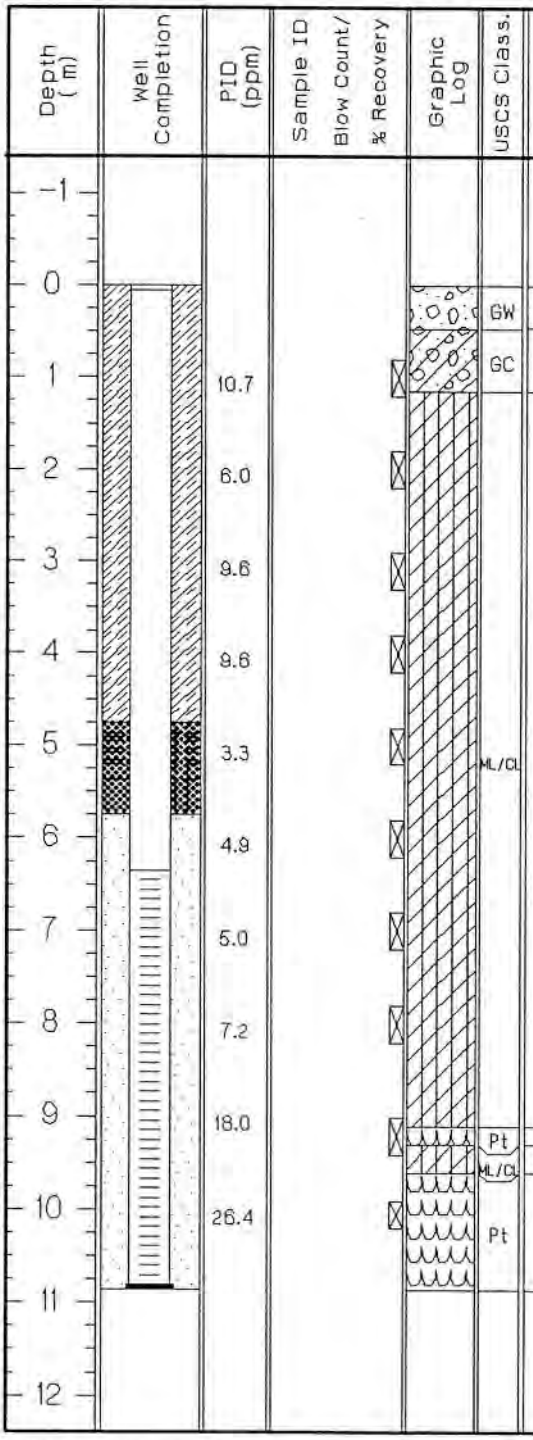
[X] Split Spoon Sample Depths.



Description

(Color, Texture, Structure)
Trace < 10%, Little 10% to 20%, Some 20% to 35%, And 35% to 50%

FILL: Sandy GRAVEL: dark grey, medium dense, subangular-sand, well graded, gravel predominantly medium to coarse grained, moist.

FILL: Gravelly SAND: orange, medium dense, well graded sand, some silt and clay (moisture content greater than plastic limit), moist.

Silty CLAY (extremely weathered Siltstone): light grey, stiff, non-plastic to very low plasticity, moisture content less than plastic limit, a little fine to medium grained sand. Orange Silty Clay fractures, a few very fine layers of moist coarse sand noted in the 1.8 to 2.2 metre split spoon sample a fine horizontal layer (4cm thick) of Clayey Sand at 3.2 metres, wet.

SILT/Silty CLAY (extremely weathered Siltstone): light grey, very stiff, non-plastic, no sand detected, homogenous clolour and texture.

As above.

As above: light greyish brown.

PEAT/COAL: very dark brown, moderately weak.

Silty CLAY: brown, stiff, moisture content less than plastic limit.

COAL: very dark brown, moderaately strong, wet.

Monitoring Well MW18 terminated at 10.85 metres below grade due to refusal.

Depth (m)	Well Completion	PID (ppm)	Sample Collected	% Recovery	Graphic Log	USCS Classification	Material Description
0			0.00-0.20 m	S 0.00-1.20 m Rec=92%		GC	Clayey GRAVEL: fine to coarse grained, well graded, dark brown; dry; with low plasticity clay and crushed rock present; no odour.
			0.40-0.60 m				
			0.60-0.80 m			SC	Clayey SAND: fine to coarse grained, sub-angular to angular, orange brown; medium dense to loose; dry; with quartz; no odour.
			0.80-1.00 m				AS ABOVE: with brown, fine to medium grained, medium dense sand.
1							Increasing low plasticity clay content with depth.
				S 1.20-2.40 m Rec=100%		CH	Silty CLAY: high plasticity, brown, dark brown to black, mottled grey to red; stiff; dry; no odour.
2			1.80-2.00 m				
				S 2.40-3.40 m Rec=80%		SC	Clayey SAND: fine grained, grey to brown; dry to moist.
						CH	Silty CLAY: medium to high plasticity, grey to brown; very stiff; dry to moist; with fine grained, dense sand.
3			2.80-3.00 m				
				S 3.40-4.40 m Rec=80%		CL	Sandy CLAY: low to medium plasticity, dark brown, grey to black mottled; moist.
						CH	Silty CLAY: medium plasticity, dark brown, mottled light grey; very stiff; dry.
4			3.80-4.00 m				
				S 4.40-5.50 m Rec=55%		SC	Clayey SAND: fine to medium grained; dry to moist; with non to low plasticity clay.
						CH	Silty CLAY: high plasticity, red with grey to brown mottling; very stiff; dry; no odour.
5			4.80-5.00 m				
				S 5.50-6.60 m Rec=100%			Various colour changes with depth (brown, orange brown, red, light grey, dark brown).
6			5.80-6.00 m

Drilling Log
Soil Bore ID: SS135

Comments
SS134 and SS135 have been assessed to represent 'soil' locations based on current ground conditions in the former sewage ponds

No surface water, sparse vegetation

Project: Anglesea Power Station		Client: Alcoa of Australia Limited	
Location: Power Station		Project No.: AUS##C02697

12-MONTH PUMPING TEST

Data Set: C:\...\Alcoa Anglesea_SB2, WB14, WB15, WB16.aqt
Date: 02/04/22 Time: 13:42:38

PROJECT INFORMATION

Company: EHS Support
Client: Alcoa of Australia
Project: AUS##C03371_2021
Location: Anglesea
Test Well: MW16
Test Date: 13 May 2021

AQUIFER DATA

Saturated Thickness: 72. m Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA

Pumping Wells

Well Name	X (m)	Y (m)
WB16	253504	5747188

Observation Wells

Well Name	X (m)	Y (m)
WB16	253504	5747188
WB14	253671	5747343
WB15	253857	5747075
SB2 (Barwon Water)	254260	5746445

SOLUTION

Aquifer Model: Confined Solution Method: Papadopulos-Cooper

T = 111.7 m^2/day S = 0.0002252

Appendix H Laboratory Permeability Results

Soil testing - Determination of permeability of a saturated specimen
Constant head method using a flexible wall permeameter
AS 1289.6.7.3-2016

Appendix B TRP Independent Peer Review Letter

Department of Energy, Environment and Climate Action

8 Nicholson St
EAST MELBOURNE, 3002
Telephone: 136 186

8 February 2024

Mr Warren Sharp
Pt Henry & Anglesea Site Asset Manager | Asset Planning & Management
Alcoa of Australia Limited
205 Coalmine Road
ANGLESEA, VIC 3230

By email: warren.sharp@alcoa.com

Dear Mr Sharp,

ANGLESEA GROUNDWATER MODEL

I am writing to inform you that the Interagency Group, representing the Water and Catchments Group DEECA, Earth Resources Regulation DEECA, and Southern Rural Water, has determined that the Anglesea Groundwater Model, as outlined in the report (12542999-REP-AngleseaNumericalModelUpdate_rev06b DRAFT – July 2023), is fit for purpose for conducting predictive modelling to inform Barwon Water's Bulk Entitlement review process and Alcoa's mine rehabilitation strategy and groundwater assessment for a groundwater licence application.

The IAG decision has been informed by an independent review process and a focus on the agreed scope of the groundwater model that does not pre-empt:

- the outcomes of future processes or work to be undertaken for groundwater related assessments; and
- any future process requirements or decisions for licence application by Alcoa or review of Barwon Water's Bulk Entitlement.

A copy of independent review report "Anglesea Groundwater Model – Review of Model Development and Calibration, January 2024" is attached.

Yours sincerely

Randal Nott
Senior Manager, Groundwater Assessment and Modelling | Water Entitlements, Licensing and Modelling | Water Resources Strategy | Water and Catchments

1. Introduction

1.1 Groundwater Technical Review Panel (TRP)

This report documents the technical review process and review outcomes in relation to the Anglesea groundwater model. The review was undertaken by the Groundwater Technical Review Panel (TRP). The TRP was convened in late 2021 to provide expert and independent review of technical groundwater investigations. The TRP was convened by an Inter-Agency Group (IAG) comprising DEECA[1], SRW[2] and DJPR-ERR[3] for the purpose to provide technical advice about the Anglesea groundwater model. The model will be used by Barwon Water and Alcoa to support groundwater bulk entitlement review and a licence application respectively.

The review is intended to critically assess the conceptual model, numerical model design, model build and model calibration. The review will provide an independent and transparent assessment of the model capability and limitations, to inform Regulatory decision makers, stakeholders and the wider community.

The two key water issues being investigated are (i) the proposed extraction of groundwater by Alcoa to fill the former Anglesea mine pit void and (ii) assessing the effects of groundwater extraction from the Barwon Water borefield[4] [i]for urban water security purposes. These issues involve interrelated technical aspects, including:

- an improved conceptual model drawing on operational, monitoring and test pumping data;
- an updated groundwater modelling tool for scenario modelling and uncertainty assessment;
- mine pit void hydrogeology;
- catchment impact assessments.

The Groundwater TRP is charged with reviewing investigation reports as to whether:

- appropriate methodologies have been applied,
- appropriate methods have been used to collect and analyse data,
- groundwater modelling is "fit for purpose",
- reasonable values and parameters have been used in calculations and computations,
- correct interpretations have been made on available and relevant data,
- uncertainty and risks have been adequately addressed, and
- recommendations and conclusions are reasonable.

1.2 Background on the TRP

The TRP is comprised of independent experts from a wide range of fields including geology, hydrogeology, modelling, geochemistry, and ecology, as outlined below.

[1] DEECA is Department of Energy, Environment and Climate Action

[2] SRW is Southern Rural Water

[3] DJPR-ERR was previously known as Department of Jobs, Precincts and Regions - Earth Resources Regulator, and it has now been incorporated into DEECA

[4] The Barwon borefield is an existing entitlement issued by a Ministerial Order in 2009 for 10,000 ML per year for the purpose of augmenting water supply to Greater Geelong customers. Barwon Water is obliged to submit a review report to the Minister about long term sustainability of resource, protect environment and improve management and will use the groundwater model to support this review.

Figure 1 - Photograph of TRP members on site (L-R: Timms, Lloyd, Middlemis, Scott)

Professor Wendy Timms (Chair of TRP)

Wendy has extensive expertise in geology, hydrogeology, and engineering, and almost 30 years' experience. She is a Chartered Engineer (Civil Engineering, Environmental Engineering) and a former Vice President of International Association of Hydrogeologists. Wendy is Professor of Environmental Engineering at Deakin University, teaching geology for geotechnical engineering, water and waste engineering and leading research in geological carbon sequestration, water tracer technology, and groundwater hydrology, especially low permeability aquitards. She has engineering project and research experience at coal, gas, uranium, metals and potash and waste sequestration sites in Australia, Asia and Canada, and has published over 200 technical reports and more than 65 peer reviewed journal papers.

Lance Lloyd (Ecology specialist)

Lance has over 30 years' experience (following a M.Sc. by research) as an ecologist in SE Australia and, in the Pacific Islands and New Zealand, in freshwater, estuarine, coastal and inland environments in fish and aquatic fauna ecology and their management requirements. His key expertise is relating the ecology of aquatic systems to the needs of management issues (especially environmental flows, ecosystem restoration and impact assessment). Lance is also the ecological expert on Southern Rural Water's Independent Technical Review Panel for the Barwon Downs Remediation and Environment Protection Plan which addresses the acid discharge issues arising from Big Swamp. He currently chairs the Great Australian Bight Resource Assessment Group, Australian Fisheries Management Authority (AFMA – 2013 to present), was previously the chair of the Translocation Evaluation Panel (Fisheries Victoria – 2004 – 2017) and a member of the Victorian Catchment Management Council (2015 -2018).

Hugh Middlemis (modelling specialist)

Hugh is a groundwater modelling specialist based in Adelaide with a degree in civil engineering, a masters in hydrology and hydrogeology, and 40 years' experience across Australia and internationally. Hugh established HydroGeoLogic in 2013 as an independent consultancy, specialising in flow and solute models, stream-aquifer interactions, groundwater dependent ecosystems and uncertainty analysis. Hugh is a co-author of best practice guidelines on groundwater modelling and uncertainty analysis, and has been appointed to expert panels, including for the Barwon Downs and Yeodene/Big Swamp remediation project, the Victorian Murray Floodplain Recovery Project and the NSW Mining and Petroleum Gateway Panel.

Peter Scott (acid specialist)

Peter is a geochemist specialising in the assessment and management of disturbance of coastal acid sulfate soils (CASS) and disturbance by mining of sulfidic rock material resulting in the generation of acid and metalliferous drainage (AMD). Peter has more than 50 years of experience in managing and minimising environmental impacts from mining and coastal land development throughout the world. Peter is a leading specialist in AMD assessment and design of mining landforms for control of AMD. Peter has established benchmark understanding of land development planning for controlling and mitigation/minimising impacts resulting from disturbance of acid sulfate soils.

1.3 Purpose of this report

This TRP report addresses the scope of work requested by the Inter-Agency Group:

- A brief explanation of the technical review panel objectives, the review process and its stages.
- A synopsis of the key elements of the review findings, in particular:
  - Are the model objectives clearly stated?
  - Is the conceptual model based on available information and fits the model objectives?
  - Does the model design and build reflect the conceptual model, fit the objectives and is it suitable for application to predictive scenario forecasting?
  - Comment on the importance of model calibration/history-matching performance and uncertainty analysis and their relevance to this model in achieving the objectives.
  - Any limitations or qualifications on the use of the model for its intended objectives.
- Any other comment from the TRP that may be relevant to modelling and model development.
- Conclusions and Recommendations about the modelling and model development. Is the model fit for its intended purpose?

2. Background on Jan Juc GMA and Anglesea

2.1 Jan Juc Groundwater Management Area (GMA)

The Jan Juc Groundwater Management Area (GMA) is part of the Torquay Basin, one of four major Tertiary depressions in the Otway Basin in southwest Victoria. The geological formations in the Jan Juc area are separated from other areas of the Otway Basin and so groundwater within the Jan Juc GMA is not connected with groundwater elsewhere in Southwest Victoria.

The Eastern View Formation (EVF) has two principal aquifers in the Jan Juc GMA. The EVF includes two distinct high permeability aquifer units that are separated by low permeability aquitards. The main aquifer units are in the Upper EVF and the Lower EVF, illustrated in the simplified conceptual model (Figure 3). In the centre of the Anglesea depression, where the sediments and coal are thickest and suitable for open pit mining (Holdgate et al 2001), there are multiple layers of low permeability sediments including:

- aquitards within the Demons Bluff Group (layers within the light grey colour in Figure 3) and,
- aquitards within the Upper EVF (layers within the orange colour in Figure 3).

The UEVF and LEVF are accessed by two major borefields operated by Alcoa and Barwon Water (BW) near the town of Anglesea:

- Alcoa borefield: 7 bores in the Upper EVF established in 1969, 4 bores decommissioned to date; historical licence to extract 4 GL/yr for industrial use relating to the former Alcoa Power Station and open pit coal mine at Anglesea; licence subject to review/amendment by Southern Rural Water (SRW) based on current investigations;
- Barwon Water borefield: 7 bores in the Lower EVF established in 2009 (5 southern bores near the Anglesea pit void; 2 northern bores about 4.5 km north of the pit); Bulk Entitlement (BE) licence to extract 10 GL/yr (average); includes trigger level conditions for the protection of the swamplands groundwater dependent ecosystems (GDEs) in the upper Anglesea River.

A timeline of historical extraction from the UEVF (Alcoa), including via the mine sump, and from the LEVF (BW) is presented in Figure 2.

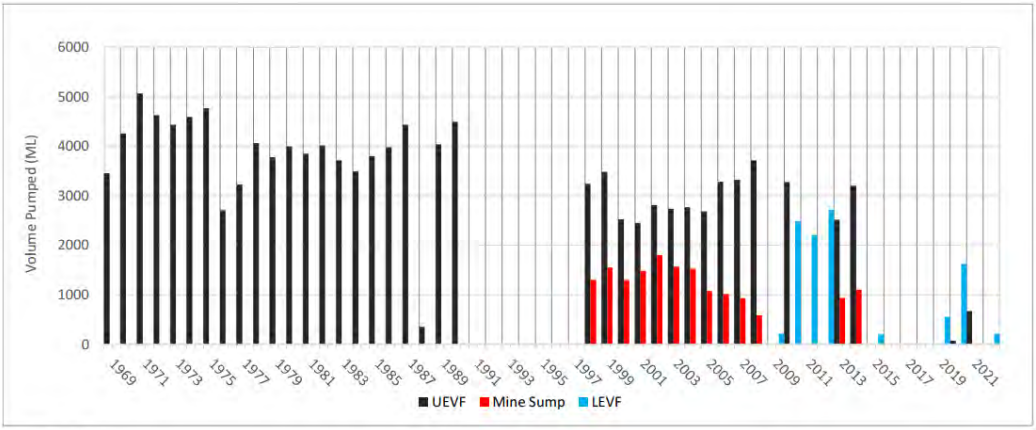

Figure Notes:

UEVF Data missing for 1991-1997, 2009 & 2011-2012
UEVF volumes prior to 1989 also include the mine sump volume
LEVF 2021 Data – Up to and including February 2022

Figure 2 - Timeline of historical groundwater extraction (after EHS Support 2022)

2.2 Background on regulatory obligations

Barwon Water's Bulk Entitlement (Anglesea Groundwater) Order 2009 authorises Barwon Water to extract groundwater from the Lower Eastern View Formation (LEVF). Under the bulk entitlement, Barwon Water must undertake a periodic review of the bulk entitlement to inform the Minister for Water about:

- the long-term sustainability of groundwater resources in the area,
- protecting the environmental values and health of groundwater dependent ecosystems, and
- improving resource management arrangements under the bulk entitlement.

Barwon Water will submit a review report to the Minister in late 2024 for the next review of the bulk entitlement. In accordance with the bulk entitlement, Barwon Water must consult with the Department of Environment, Land, Water and Planning (DELWP, now DEECA) on the review process and present the subsequent review plan to the Minister for Water for approval. Barwon Water carried out a groundwater pumping test at the Anglesea borefield from January to July 2022 to inform the review of their bulk entitlement and associated monitoring program. Data collected from the pumping test was used to identify the impacts of taking groundwater and support the process of reviewing and updating the local groundwater model.

Alcoa has a regulatory obligation to develop the Anglesea Mine Rehabilitation and Closure Plan (MRCP) for review and approval by Earth Resources Regulator (ERR). The relevant legislation is the Minerals Resources (Sustainable Development) Act 1990 (MRSD Act). Alcoa's current proposed approach is to fill the mine void with groundwater pumped from the UEVF. This proposal will require a licence application to SRW.

The relevant legislation for assessing licence applications (SRW) and Bulk Entitlements (DEECA) is the Water Act 1989, particularly matters that are listed under s40 of the Act. These matters include a range of water availability, water quality and environmental considerations.

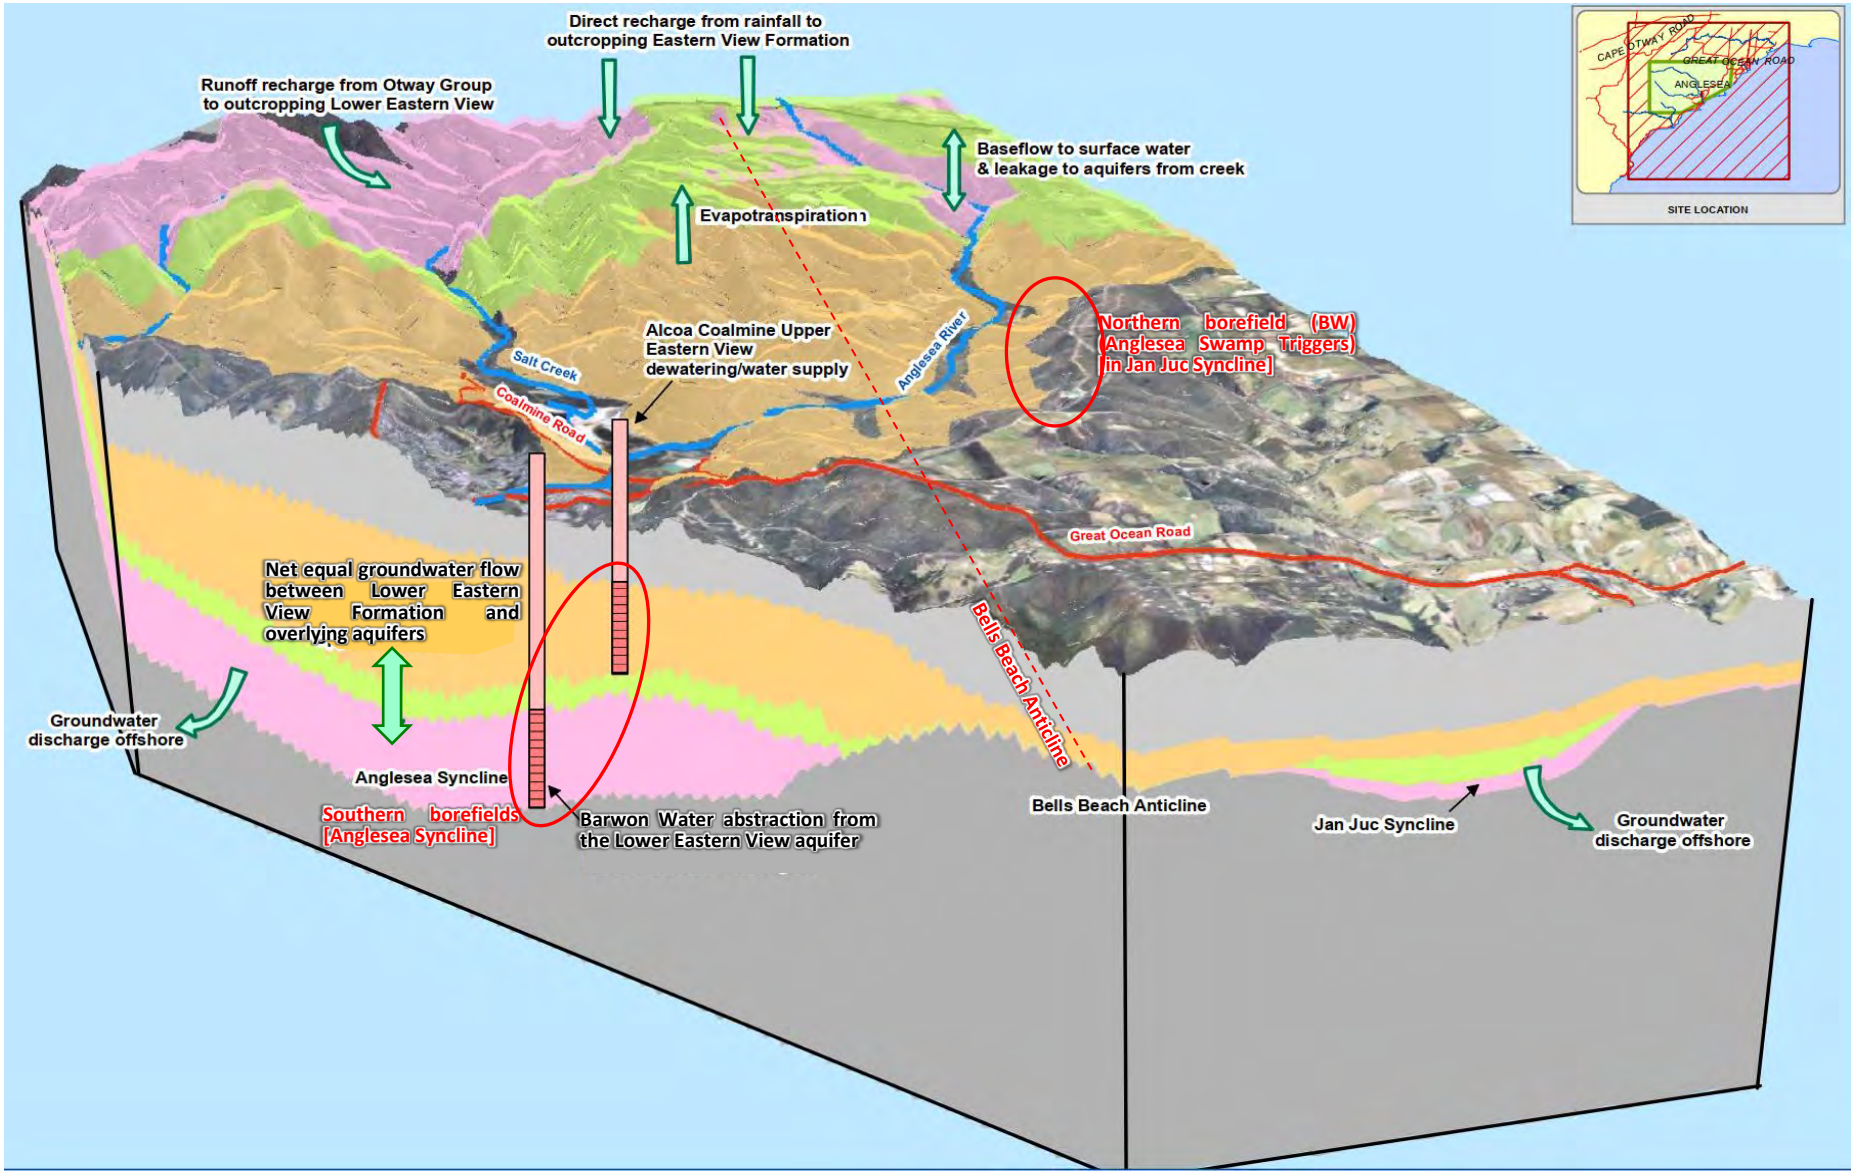

Figure 3 - Anglesea conceptual groundwater model (after GHD 2013, 2022)

2.3 Anglesea Groundwater Model

Barwon Water commissioned consultants GHD in 2009 to develop a numerical groundwater model of the Jan Juc GMA aquifer system for application to borefield sustainability and impact assessments. The model was updated in 2013 and 2019 and has undergone a major update in 2022.

The 2022 Anglesea model update involves using the latest numerical code, updated layer structure and parameterisation schemes, the latest methods of history-matching to observation data, including new information gleaned from the 6-month pumping test, and with integrated uncertainty analysis methods.

The intention is to develop a groundwater model representative of shallow and deep aquifer systems that is suitable for the ongoing water management and planning needs of both Barwon Water and Alcoa, to support:

- the Barwon Water Anglesea borefield planning, management and approvals works under the Bulk Entitlement (BE) process, including periodic model updates and re-assessment of sustainability.
- the Alcoa mine closure and rehabilitation planning and management works, including the licence application to SRW for long-term groundwater abstraction to fill the pit water body.

2.4 Anglesea Mine Rehabilitation and Closure Plan (MRCP)

A draft Anglesea Mine Rehabilitation and Closure Plan (MRCP) was submitted by Alcoa to Earth Resources Regulator (ERR) in September 2017. It was estimated that allowing the pit void to naturally fill and form a water body (lake) would take 50-100 years to reach a final level of between -4 to +4 metres AHD (EHS Support, 2017). Alternatively, filling the pit void with groundwater extracted from the Alcoa UEVF borefield could reduce the timeframe, and enable a more rapid implementation of the MRCP.

In September 2020, Alcoa submitted a Groundwater Impact Assessment (GIA), evaluating risks to the environment and third-party users associated with a proposed 12-month groundwater pumping test of the UEVF aquifer. In October 2020, Southern Rural Water (SRW) issued an amended groundwater licence for that purpose.

On 13 May 2021, Alcoa commenced the groundwater pumping test of the UEVF aquifer, with the extracted groundwater being discharged to the pit void lake, and with monitoring and modelling investigations ongoing. The pumping test was paused on December 8, 2021 after 672 ML was extracted, about 44% of the licensed volume, while the data from the first 6-months of pumping was evaluated.

3. The TRP review process

3.1 Objectives of reviewing the Anglesea groundwater model

The TRP was engaged by DEECA in November 2021 to provide independent technical expertise:

- to review the development of the Anglesea groundwater model and its application to impact and resource assessments in the Jan Juc GMA
- to provide advice to the Inter-Agency Group comprising representatives of DEECA, SRW and DJPR/ERR.

The TRP brief is outlined in section 1.1.

3.2 Processes and stages of the TRP model review

The TRP review process involved several stages:

- inception meeting, reading of background reports and a site visit on 25 February 2021 (Figure 1),
- reviews of updated conceptual and numerical model report submitted by Alcoa and Barwon Water to the IAG (see Table 1 lists and references),
- several meetings with Alcoa, Barwon Water, and their consultants, facilitated by DEECA,
- several meetings with the Inter-Agency Group, facilitated by DEECA,
- meetings for internal discussion amongst TRP members.

Apart from the site visit, all meetings were conducted by videoconference.

Outcomes of the TRP process are summarised in

Table 1:

Table 1 - Summary of TRP review process

Timeframe	Stage	Description
December 2021 to January 2022	Inception, Site Visit and Conceptualisation (initial)	Inception meeting 3 December 2021, with DEECA and Inter-Agency Group (IAG includes ERR, SRW & DEECA), and including briefings by Alcoa, Barwon Water, and their consultants. Review of technical reports provided by DEECA, notably: • previous investigations and the numerical model development (GHD 2013, 2019), and related reports on ecology and acid mobilisation • the conceptual hydrogeological model ('CHM'; EHS December 2021) • the numerical model design for the 2022 update (GHD December 2021). Outcome: TRP initial review reports to DEECA on conceptual hydrogeological model and numerical model design.
March 2022	IAG workshop	TRP and IAG workshop facilitated by DEECA, with Barwon Water, Alcoa and their consultants, to discuss the initial TRP

Timeframe	Stage	Description
		review, and the updated (March 2022) reports on the CHM and numerical model design, and the comments register.
May-June 2022	Calibration 3b	TRP review of the GHD numerical model calibration report version 3b (May 2022), including updates to address previous TRP review recommendations on the CHM and model design (TRP letter to DEECA, 24 June 2022).
July 2022	TRP/IAG Workshop	TRP and DEECA workshop on 15 July 2022 to discuss TRP response to additional questions from the Inter-Agency Group on the model suitability, historic impact (hindcasting), baseline scenario, BW pumping and risk assessment (TRP memo to DEECA, 22 July 2022).
September 2022	IAG workshop	TRP and IAG workshop facilitated by DEECA, with Barwon Water, Alcoa and their consultants, to discuss the TRP review report (June 2022) on the numerical model calibration version 3b (GHD May 2022). Key issues discussed included the Quantities of Interest (QoI; or key model forecasts), and the acid generation/mobilisation assessment methodology.
October 2022	Conceptualisation (update) Calibration 4b	Review of updated conceptual model report (EHS Sept 2021) and numerical model calibration version 4c report (GHD Oct 2022). Outcome: TRP review report on use of model for scenario forecasting and draft QoI (TRP memo to DEECA, 14 October 2022).
August 2023	Calibration 6b	Review of updated numerical model calibration version 6b report (GHD Oct 2022). Outcome: The model is "fit for purpose" and can proceed to testing "Predictions of Interest".
October-December 2023	TRP Review Summary	Preparation of updated summary report on the TRP process and outcomes.

225

226

227

228

4. Findings of the model review

4.1 Responses to key questions

4.2 Model Objectives

The model objectives are clearly stated in the modelling report (GHD 2022) in terms of developing a single Anglesea groundwater model that is suitable to meet the needs of the ongoing water management and planning obligations of both Barwon Water and Alcoa via investigations, monitoring and periodic model updates to support:

- the Alcoa mine closure and rehabilitation planning and management works, including the licence application to SRW for long-term groundwater abstraction to fill the mine pit void;
- the Barwon Water Anglesea borefield planning, management and reviews under the Bulk Entitlement (BE) obligation, including re-assessment of the sustainability of groundwater extractions for urban water security purposes.

The latest methods of groundwater modelling and uncertainty analysis have been applied. This allows for input data and conceptualisation uncertainties to be carried through to their influence on model forecasts and their uncertainties. The model results for the history match calibration and the scenario forecasts are presented in the following terms, which is designed to aid decision-making:

- magnitude of effects of groundwater extraction
    - eg. groundwater levels and drawdowns in the EVF and swampland aquifers; river flow-duration and zero flow period changes with time; aquifer flux exchanges with rivers and swamplands; pit lake levels and water balances, etc.
- probability of occurrence of those effects
    - eg. the key metrics of 5%, 50% and 95% likelihood ('P5, P50 and P95') of predicted impacts exceeding or not exceeding established triggers at sensitive/key sites such as groundwater dependent ecosystems and at stream flow gauges (DELWP 2015a,b), and with consideration of climate change effects (DELWP 2020).

Results are presented in catchment-wide spatial terms (and also for the upper and lower catchments and specific locations), such as the area where 0.1m drawdown is predicted to be exceeded with a suitably justified probability.

4.3 Conceptual Hydrogeological Model (CHM)

The Anglesea conceptual hydrogeological model is illustrated in Figure 3. The Anglesea catchment is a very complex system and it is very challenging to quantify precise predictions of ecological hazards or impacts given this complexity and the gaps in historical data. Some of the key challenges are:

- There are complex processes that generate acidity and mobilise metals, including flushing events after drying of soils and swamps and water-rock interactions with underlying geology.
- There are complex processes influencing water quality in the estuary with dynamic conditions. For example, buffering capacity of the water to acidity and hydrodynamics of variable surface flows and interactions when the sand bar is open to the ocean.
- It is possible that small changes or short-term changes in the system could result in significant ecological effects. For example, a small watertable drawdown could significantly impact flora and fauna species in swamp and estuary if that results in a mobilisation of significant acid loads that are not buffered by the estuary water chemistry.

- Current understanding of the relative significance of natural variations and human activities on the system is limited. There is currently uncertainty in quantifying the influences of mining and/or groundwater extraction from the UEVF and/or the LEVF, particularly with time-lags for affects over many years and large variations in rainfall.
- A combination of modelling with uncertainty analysis and monitoring will be required to inform risk-based approaches that include adaptive management of groundwater extraction rates and locations.

That said, the conceptual model is based on the available information and is designed consistent with the model objectives, with the following features are adequately represented in the numerical model (with reference to Figure 3):

- catchment extent and hydrogeological setting (Anglesea and Jan Juc synclines)
- groundwater flow in the main aquifer systems (EVF and alluvial swamp aquifers)
- rainfall recharge, creek flows, evapotranspiration, and groundwater interactions, including climate variability (eg. history match variability and forecasts with/without climate change)
- groundwater pressure changes at the coast for saline intrusion risk assessment
- Alcoa and Barwon Water borefield pumping, and third party users
- Alcoa pit water body levels, water balance and groundwater interactions
- groundwater particle tracking capability to evaluate capture zones around pit water body and borefields
- simulation of dynamic watertable variability in the alluvial swamp aquifers (ASA), as a proxy indicator of acid generation/mobilisation risk across model scenarios (uncertainties apply).

The model is designed to assess the effects of climate change on key forecasts of interest, such as changes to groundwater recharge rates, changes in evaporation, particularly with the modelled pit water body, and potential future sea level rise. The TRP identified a potentially significant issue with the coastal boundary at the design stage, which was corrected.

An appropriate balance has been achieved between model design complexity and simplicity, and implementation in the numerical model, consistent with best practice guidelines, including for uncertainty assessment (Barnett al 2012; Peeters and Middlemis 2023) and climate change (DELWP 2020).

4.4 Model Design, Build and Predictive Purpose

The model is capable of simulating groundwater levels, groundwater flows, and surface water flows; however, it is not designed to directly simulate the processes of acid generation and mobilisation, or ecological impacts. The investigation into those would require different tools and assessment, for which the model results are potentially critical inputs.

The model has reasonable capability in terms of aquifer system processes. For example, the model reasonably replicates the pattern of observed groundwater response in the deeper aquifers to pumping from the deeper aquifers (UEVF, LEVF). The model also reasonably replicates the lack of groundwater response observed at key locations in the shallow Alluvial Swamp Aquifer (ASA) to groundwater pumping (see Figure 4 below, after GHD 2022 Figure 3-16 and 3-7).

The model reasonably replicates these dynamics in most monitoring bores in the main EVF aquifers for the history match period (1968-2020), although there are few nested bore sites (with screens in all units) close to the area influenced by mining activities (e.g., only two ASA bores near the Alcoa mine; WTOB1, WTOB2). Interestingly, Figure 4 shows minor decreases in measured ASA levels at times that do not appear to be related to pumping effects, suggesting climate effects may be important. Although the groundwater level drops are minor, they may be enough to expose acid sulfate soils (ASS) in the swamplands. A comparison of different model scenarios (with and

without pumping) could provide insights into the effects of groundwater extraction and climate on the shallow aquifer system, and the investigation of hydrological conditions that may be associated with acid mobilisation events.

4.5 Model Performance and Uncertainty Analysis

Model calibration/history-matching performance and uncertainty analysis and their relevance to this model is important in achieving the model objectives.

Available observation data have been used for model calibration/history-matching, with metrics including aquifer extractions for water supply and pit dewatering, groundwater levels and trends, stream flows, and post-mining pit lake levels and water balances/fluxes.

The model history-match period 1968-2022 includes a very wide range of stresses including climate variability (rainfall-runoff, recharge/discharge and evapotranspiration, above and below average rainfall periods), groundwater pumping, pit void rehabilitation and development of the

water-body ('pit water body'). The model commences prior to mining of the main pit and groundwater pumping that supported the first power generation at the site in March 1969.

The reasonable calibration/history-match performance provides confidence that the Anglesea model is a suitable predictive tool under a range of climate and other stresses for surface water and groundwater interactions, interactions with the pit, interaction between the main aquifers (UEVF, LEVF and ASA), groundwater trends, water balances, pit water levels, flux exchanges and parameter realisations.

The model will be a useful tool for scenario forecasting, provided that the inherent limitations of modelling are acknowledged (e.g., see sections 4.3 and 4.6).

The large uncertainties that are inherent in modelling this complex system means that the model results should be considered within a risk management framework for adaptive management. The uncertainty assessment methods applied to the model history-match and the predictive scenario forecasts are consistent with best practice methods (Peeters and Middlemis 2023) and are designed to inform a risk management framework. Confidence in future predictions can be improved with a combination of periodic updates, to the modelling and uncertainty analysis, monitoring and investigations. The model is also suitable for use in a data worth analysis to identify optimum sites for filling gaps in the monitoring network (eg. in the ASA, such as in the lower catchments to augment the existing bores WTOB1 and WTOB2).

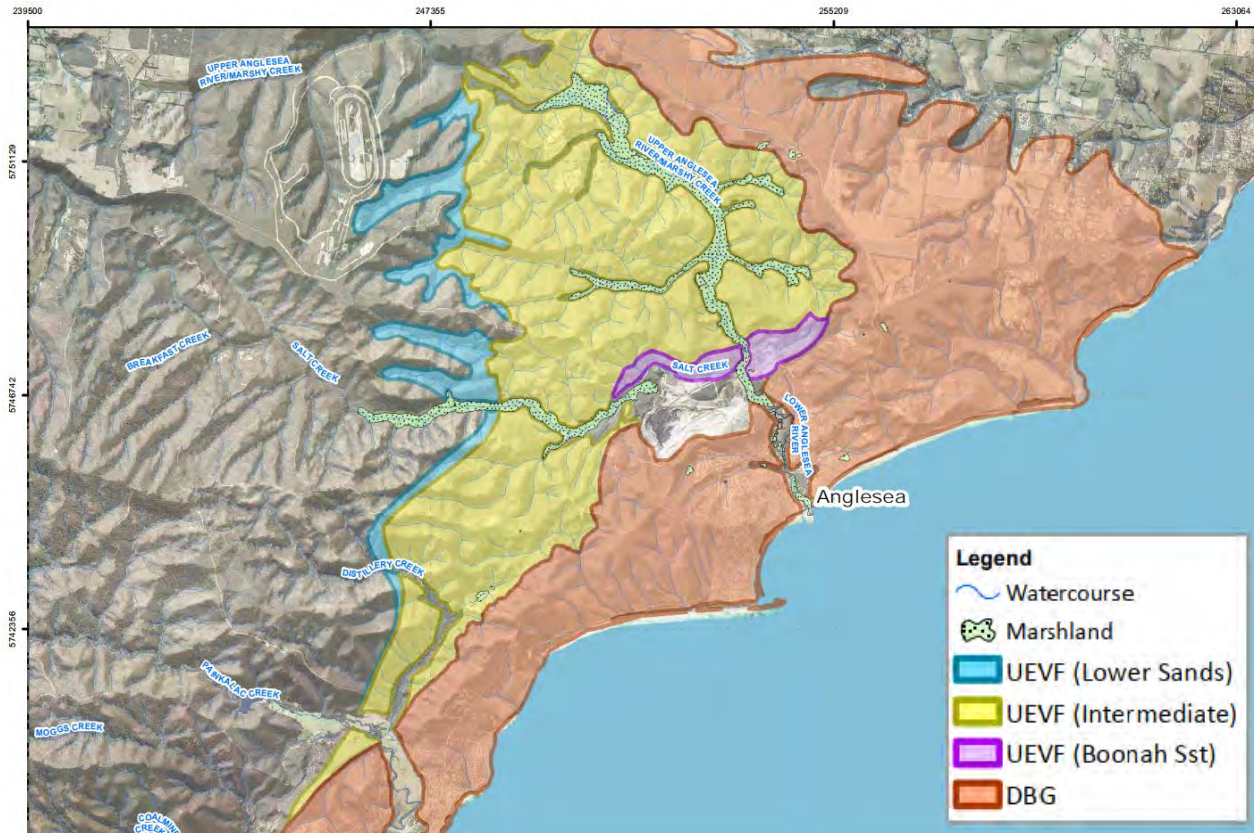
4.6 Model Capability and Key Limitations/Qualifications

The model has demonstrated capability for directly evaluating local to catchment scale resource management issues such as the effects of pumping in terms of groundwater levels and interactions with the pit water body, swampland sediments, stream flows and coastal boundaries. The modelling report (GHD 2022) outlines the main uncertainties and limitations applying, and proposes reasonable actions to address the issues.

4.6.1 Acid generation/mobilisation

The groundwater modelling is designed to investigate and unpack the influence of key processes such as climate, pumping and mine pit voids or water bodies. It provides output data for input to ecological impact and acid mobilisation assessments, and it can provide other objective insights, as follows.

The generation and mobilisation effects of acid sulfate soil (ASS) components (acid sulfates, reduced iron, low dissolved oxygen and acidity and dissolved metals) is a highly complex process. The alluvial soils present in the upper catchment of Anglesea River in the Salt Creek and Marsh Creek swamplands that support the Alluvial Swamp Aquifer (ASA) contain sulfide minerals. The sulfide presents in the alluvials that support the ASAs are derived from erosion of sulfidic carbonaceous material in EVF, Salt Creek Formation and Anglesea River Formation where exposed in the catchment (Maher 2011, Tutt 2008); see also Figure 5. Additional sulfate released into the shallow groundwaters of the ASAs is captured in the peaty soils and converted to monosulfides, which remain inert in saturated soils. When the groundwater level in the ASA is lowered (e.g. during a long dry spell), these sulfidic alluvial soils are exposed to oxidising conditions that generate the acid sulfate salts. Minor drawdowns of ~0.1m can generate acidic sulfate salts in the exposed soils, and mobilisation of these acid sulfate salts can occur when significant rainfall recharges the aquifer, flushing the acid sulfate components to the downstream receiving environment.



382 Figure 5 – Summary map of regional geology (after EHS Support 2022, Fig.5-6)

383

384 A conceptual model of the role of the swamplands on surface water flows is shown in Figure 6
385 (after GHD 2022). The most important processes in the model include:

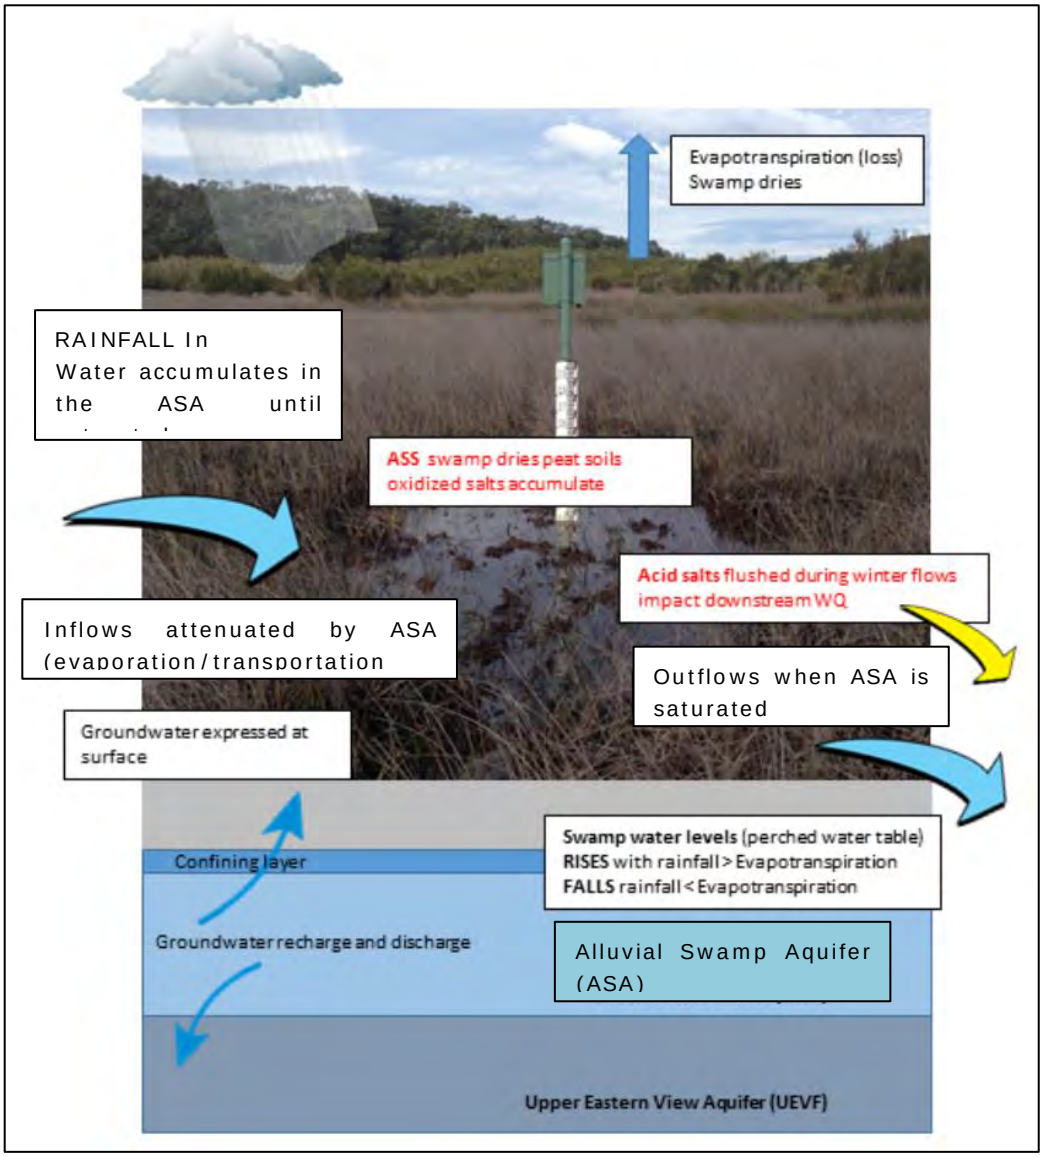
386 • During summer and other dry periods, water is lost from the ASA by evaporation and by
387 evapotranspiration from vegetation. This lowers the ASA water levels and dries and oxidises
388 the upper layers of peat in the swamplands.

389 • During wetter months, the ASA water levels increase and the soil profile is wetted up. While
390 very large flows can pass through the swamplands to the lower catchment, much of the
391 surface flow and rainfall is attenuated until the soils of the swamplands are saturated.

392 • The attenuation of surface water flow by the swampland communities increases the duration
393 of cease-to-flow periods in the downstream Anglesea River and Salt Creek, and subsequently
394 the estuary.

395

Figure 6 Conceptual model of interactions between surface water and groundwater in swamplands on the Anglesea River. In dry periods, the swamp soils dry and groundwater levels fall. Initial rainfall is attenuated by swamp until the soils are saturated and then surface water can commence to flow in downstream waterways (after GHD 2022). Note that with the lowering of the watertable in the ASAs oxidation products are mobilised into the porewater within the peaty soil of the ASA, and only are released when the swampy soils reach saturation, and the Anglesea River begins to flow, this can happen rapidly, slowly or not at all.



The groundwater model can be used to estimate the ASA drawdowns, for example from scenarios with and without borefield pumping or climate change effects, and the predicted drawdowns can be (indirectly) input to a benchmarking assessment of acid generation and mobilisation events using data on past events, or for predictive purposes.

This also means that, since the groundwater model focuses on groundwater (drawdown) in saturated materials, it does not directly evaluate the significance of other processes for oxidising ASS and metal mobilisation, such as in the unsaturated zone above the water table. However, the modelling does simulate the spatial and temporal distribution of the depth to water table, along with depth-duration-frequency curves in key areas such as the ASA, and how that changes over time in response to anthropogenic and natural stresses, for application to such assessments.

The TRP has recommended that water quality triggers be developed within the Alcoa Area of Interest (in parallel with the groundwater drawdown trigger) for ASS investigations and adaptive management. To be clear, trigger values are determined after a geochemical analysis task that uses outputs from the groundwater model for a set of key predictions of interest (or 'quantities of interest'). For example, key predictions may be designed to quantify the probability of drawdown metrics (e.g. 0.1 or 1m or 2m drawdown) at specific points or areas (e.g. Alluvial Swamp Aquifer) for specified time frames, because that may be relevant to acid mobilisation processes. The range of results from these key predictions form key inputs to the geochemical analysis of the consequences of such outcomes, which can then help determine trigger values for adaptive management purposes. In some cases, there are already agreed metrics that can be used as trigger levels or as quantities of interest, such as the drawdown metrics set out in the Ministerial guidelines for the protection of GDEs (DELWP 2015a). Scenario forecasting and differencing could provide groundwater model outputs for use in detailed analysis to gain such insights to acid mobilisation and thus to confirm whether or not the combined groundwater modelling and geochemical analysis methodology has suitable capability for the assessment acid-related effects.

4.6.2 River flow

The model simulates river flows and discharge to the top of the Anglesea estuary on a daily basis, based on rainfall-runoff variations across the Anglesea catchment, and fluxes between surface-groundwater including baseflow. These processes include groundwater discharge to surface waters and losses of surface water through river or stream beds into underlying layers. The model performance for river flows and frequency-duration will depend on good matches of surface survey elevations and water levels at key ASA monitoring bores and stream flow gauges.

During large first flows after a prolonged period of low or no flow, significant volumes of acidic water containing reduced iron can be flushed down the catchment and estuary. Flows at or above 10 ML/day occur only 10% of the time in the Anglesea River (Marshy Creek) and Salt Creek systems. Since 2009, there have been a number of high flows greater than 100 ML/day. During these high-flow events, significantly higher peak flows were generated in Salt Creek than in the Anglesea River. However, the high flow events in Salt Creek are short in comparison to the Anglesea River, where flows are lower but for a longer duration, which results in higher total flow volumes. Since 2009, higher total annual flow volumes normally occur in the Anglesea River (Marshy Creek) than in Salt Creek.

Both systems are highly ephemeral with prolonged cease-to-flow periods: 65% for Salt Creek and 50% for Marshy Creek. Turned around, these values mean that Salt Creek flows for only 35% of the time and Marshy Creek for 50% of the time. The long cease-to-flow periods are exacerbated by the natural swampland communities in both systems needing to become saturated before commencing to contribute baseflow to downstream waterways.

4.6.3 Groundwater drawdown in the swamps

The groundwater model is designed to evaluate drawdown in the swamps, although that is subject to different levels of uncertainty in different parts of the catchment given the natural complexity of the system and with limited data coverage.

Groundwater levels in layer 1 of the model (ie. the swamps) is a balance of vertical inputs from rainfall and upwards flow from groundwater, and vertical losses due to evaporation and downwards flows to deeper groundwater (as shown in Figure 6). There are also horizontal flows through the layer 1 sediments, down the catchment.

The model is capable of evaluating various scenarios of groundwater drawdown in the swamps that may potentially occur with:

- dry periods with limited rainfall and/or increased evaporative losses
- potential influence of the mine pit void and/or changes in stream bed losses
- potential influence of groundwater pumping from the Upper EVF (e.g. Alcoa) or Lower EVF (e.g. Barwon Water).
